Along the road's eastern part the whole country has changed since the colonist generals engineered its making. Valley Forge

"Thank-You-Ma'ams" Were Numerous.

attained a place in history and became an everlasting memorial to Washington. Gettysburg attained a place in history and became an everlasting memorial to Lincoln. Philadelphia spread her metropolitan airs over the vicinity, and the Forbes road was graced with beautiful country estates and well-groomed suburban towns. The Pennsylvania Dutchman and the Quaker covered the road's original clay with macadam and dotted the hillsides with large barns and small houses. The trolley worked its way into the district and the toll-gate changed its program to make automobiles the topliner.

The western part of the Forbes road is the same old mountain highway. It is still a trunk line through a wild country, full of rattlesnakes, trees, and rocks, where wide perspectives have no trace of habitation, cultivation, or epulation. The road is an air line. It goes over the mountains as nearly straight as its builders were able to make it. In some places it is simply a traveled course on the naturally flat mountainside. In other places it is a shelf hewn with difficulty in the native rock. It is fenced with thick forest, except where it rises above the trees and sticks boldly out on top of some ridge or mountain crag. It rises in a steady ascent for 5 and 6 miles at a time, simply to run down into the next valley, which is valley only by comparison, because the lowest level is high above the sea. Almost all of the clay which originally surfaced the road has been washed away. For scores of miles the road is simply a trail of bed rock, littered with loose stones. Every two hundred feet there is an immense waterbar. These were put on the road originally to turn the course of water from heavy rains into the gutter and thus prevent the washing away of the road. The road has been long since washed away. The waterbars now keep the rains from washing the loose stones off the jagged rock foundation.

In the valley towns, whose only excuse for being seems the mere habit of existence, are taverns whose halls once echoed the boisterous merry-making of stage coach travelers; where the tavern keeper once poured bad wines down the dusty throats of thirsty stage drivers, at whose tables tired passengers once sat down to boiled dinners. Some of these taverns have obtained a new lease on life. The village loafer has been moved to the far corner of the bar to accommodate the begoggled motorist, down whose dusty throat the tavern keeper now pours bad whisky. At the tavern table the modern knight of the road feasts on fried chicken, apple butter, and other substantials of a period before the Astor butted into the hotel business, but not so long ago as to have been forgotten when a Michigan-made stove transplanted the original fireplace.

There is Old Joe at McConnellsburg, whose memory far exceeds his age and who recounts more traditions of these everlasting rocky hills than were ever set down in authentic history. He knows the man who invented the mighty brake with which the mountain wagons are held against perilous flight

Forbes Road Over Alleghenies Has Steep Grades.

down the steep grades, and he thinks he knows the exact dialogue between George Washington and General Forbes when they discussed the surveying of the highway. He makes a specialty of automobilists. Over 500 cars have passed through McConnellsburg this year. Joe has entertained nearly 300 parties and expects to exceed that figure by the time cold weather comes.

The man who sells everything from rattlesnake belts to self-rising pancake flour has added gasoline and cylinder oil to his list and is local authority on automobiles. He says that there have been more Packards over this route than any other car and that over thirty Packards passed through McConnellsburg during the last two weeks.

Mr. Waldon's record run was his third trip over this road. Each year the Packard Motor Car Company sends its cars over thousands of miles of the roughest roads in general testing and

On Top of Little Round Top at Gettysburg.

development work. The long, hard runs across Pennsylvania suggested the fitness of the Allegheny Mountain district as a permanent testing place. Consequently a Packard camp was established at McConnellsburg and three experimental Packards were put through their paces in that vicinity. For a fortnight these cars were driven by different members of the Packard executive staff, engineering department and men from the factory. Different parties of Packard dealers and several Packard owners were brought to the camp to see the cars perform over Cove Mountain and other difficult stretches of road in the vicinity. So successful was the work accomplished and so extreme was the test given the cars that the Packard company is preparing to erect a permanent garage on Cove Mountain, near McConnellsburg, as headquarters for future testing.

There had been no through trips from Pittsburg to Philadelphia and return until Mr. Waldon first attempted to drive a Packard over the road in one day. This summer he essayed to establish a record that would test the ability of the car in continued hard running over a mountain road, in whose entire 300 miles there is no chance for high speed running and on which a fast record must be made absolutely by steady plugging. The result is the present record, at which the automobilists who have traveled in this country marvel.

Mr. Waldon left Pittsburg at 4 o'clock in the morning with a party of five in a standard touring car. The first half century of the trip was made before dawn over that hilly, tortuous road leading to Bedford Springs, which is familiar to all of last year's Glidden tourists. From Bedford the course turns northeastward through the very heart of the mountains and then runs eastward through Chambersburg and Gettysburg to Lancaster, where it strikes the famous Lancaster Pike leading into Philadelphia.

The foothills of the Alleghenies begin immediately out of Pittsburg and our early morning ride was simply an unbroken struggle against grades and waterbars. The brakes had to be used on both sides of each mountain. For mile after mile the car would be tossed from "thank-you-marm" to "thank-you marm," until finally it reached the apparent top of some ridge, only to descend by an equally arduous road to the bottom of a valley, whence it would rise again through foothills and finally onto the last, long climb of the next mountain ridge.

When daylight succeeded Prest-O-lite, the view from each height showed in the hazy distance a long, blue bank on whose crest an occasional break in the forest marked where the road 25 miles away touched the clouds. "Beating it" between crests meant simply a continual zigzagging from one side of the road to the other in order to strike the waterbars obliquely and rise over them with undiminished speed but with lessened jolt. Up hill and down hill, it was the same steady 25 to 30 miles an hour. In one, two, three order the wheels slammed over the waterbars, the car was yanked straight again and then pulled to the right of the road to take the next obstruction.

There is no let-up in these waterbars. Two hundred feet apart they are like rough ties in a giant, railless railway between Philadelphia and Pittsburg. Even when the road swept down the eastern face of the last mountain ridge and into the rolling farmland of eastern Pennsylvania, even when the now leveller road became a comparatively smooth macadam—still the waterbars remained to check the flight. Record breaking continued just a persistent struggle against stubborn obstruction. Since 4 o'clock in the morning Waldon had stopped only while an exploded tire had been repaired and at noon to feed the car with gasoline. The human stomach had to be satisfied with a cold lunch carried in the car.

Occasionally a slanting pole across the road meant a toll-gate and a brief respite from the bouncing, tiring journey; occasionally a small village meant a brief respite from the unpopulated hills or from the wearisome quietude among the apathetic Pennsylvania farmers. Not until the refining influence of Philadelphia was approached and the Lancaster pike had become a boulevard through beautiful suburban villages was there a restful breath or an easing up of the tense attitude that had been taken to conquer the roughness of a highway which was built for stage coaches and seems to have a natural protest against its adoption by motor cars. Then the town marshal took the place of the waterbars and stood with almost the same frequency on the road, waiting to arrest progress if progress gave him the chance by violating speed laws.

Really a record run from Pittsburg to Philadelphia should end at the city line. It seemed that night, wandering into Quakertown over a smooth but uncertain way through Fairmount Park, that we were trying impatiently to get done with an anticlimax. The noise of a big city does not appeal strongly to the reactive nerves of a record breaker who has finished his job. His atmosphere is the wild hillside or the open road where the wind blows the dust across an astonished countryside. His hotel is the country tavern. His garage is the country hardware store, where gasoline is sold at prices that would make the Standard Oil Company blush with shame. His lights are the glaring headlights which peer into the darkness before dawn or the deep black of midnight and tantalizingly beckon him to go on faster and faster into the secret paths of the mountains.

There should be an inn at the city line; an inn for record breakers; an inn like we used to have in the old mediæval times when the knight errants rattled into a stone-flagged courtyard, jumped from tired horses and thumped into the great room where mine host set before them bread, meat and wine, according to the best style of historical novels—a room where they could loudly bang on the tables and, sprawling on crude benches, as loudly gabble over the happenings of the day. Enter then the record breakers, noisily:

"What ho, varlet! Meat not steaming on the board? Think ye that we, who have ridden since the cock crowed, a hundred leagues o'er yon accursed mountains in our valiant Packard, are not raving with thirst and nigh to perishing of hunger? We have smashed the record and right heartily would we eat. Beat it to the kitchen, you mutt."

Valley Forge Lies Close to Old Forbes Road.

Latest Doings of the Aerial Brigade

Attaching Ropes to Basket for Malecot Combination Airship.

PARIS, Aug. 22.—It is an easy job that the eight policemen and one brigadier have at the Issy-les-Moulineaux ground from 4 to 6 a. m. every day, for although the Parisian is naturally an early riser he is not equal to reaching this distant military ground at daybreak. Consequently the aeronauts can operate in that isolation that Wilbur Wright sighs for.

Captain Ferber, inventor of the Farman type of aeroplane, has been busy every morning with his new biplane, constructed and engined by the Antoinette company. Having been recalled to active service, the captain has made a gift of his new machine to M. Legagneaux, a young enthusiast, who after three trial trips succeeded in covering a distance of 280 yards under official observation, thus winning the third of the prizes offered for a flight of not less than 200 metres. The first two were won by Delagrange and Bleriot.

Ferber's machine, known as the *Ferber IX*, is a nearer approach to the Wright Brothers' idea than any aeroplane built in France. Its bearing surfaces consist exclusively of two superimposed planes. There is no tail; the elevation rudder is in front and the lateral rudder in the rear. On the first trials the balance was not perfect, the rear rudder too did not appear to have any power to bring the apparatus into the wind as it should have done, the aeroplane falling off whenever it was taken a point or two out of the eye of the wind. Starting is effected by means of a couple of pneumatic shod wheels in tandem and mounted on powerful hydraulic shock absorbers.

Gastambide-Mengin has the honor of being the first to rise in the air on a monoplane machine with two persons on board. The performance was made at Issy one morning last week, the distance covered being about 120 yards. The machine was engaged for the 200 metres competition, but was unable to run owing to the ground being closed at 6 o'clock just as the apparatus was ready to compete.

A New Aeroplane Recruit at Issy.

A new recruit at Issy, the tri-plane Bousson-Borgnis, failed to make a good impression on its first outing. The new aeroplane is a curious looking structure, having three curved, superimposed bearing surfaces with a strong resemblance to the wings of a huge bird. At the front are a couple of elevation planes also shaped like the wings of a bird. The entire apparatus is mounted on a stout carriage borne on three small pneumatic tired wheels, the driving power being a six-cylinder engine operating a four-bladed propeller at the rear through shaft and chain drive.

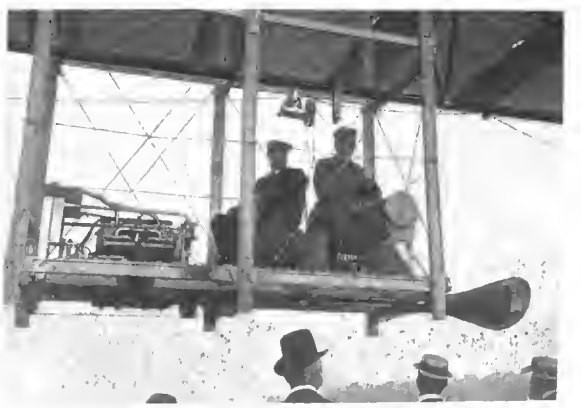
Sky pilots are seeking to escape from the annoying restrictions of Issy, the Antoinette company having already secured a training ground on an island in the Seine, some distance above Rouen. Here they have a length of about one mile by three-quarters of a mile, where no restrictions whatever are in force and which cannot be reached by inquisitive sightseers. Delagrange is looking for a private ground before resuming work and Farman will also make a change if possible.

An aeroplane section will be included in the Paris automobile salon this year for the first time. The section will be a purely commercial affair, only current models of aeroplanes and aeronautical motors as placed on the market being on exhibition.

Issy-les-Moulineaux now has a hybrid in the form of a cross between a dirigible balloon and an aeroplane, a production due to the inventive genius of M. Malecot. It consists of a cigar-shaped gas bag inflated with hydrogen and having a lifting capacity of 600 pounds, or sufficient to raise its machinery, two passengers and a small amount of ballast. But, unlike the ordinary dirigible, the Malecot machine does not depend entirely on the lifting power of its gas.

Immediately below the gas bag is the aeroplane portion, consisting of a couple of parallel planes running the full length of the lower part of the balloon and terminated by a vertical rudder. Below this again is an open wooden cage on the floor of which is installed a four-cylinder water cooled automobile engine, the installation and fitting of which is exactly similar to that of a car, with the exception that instead of driving a rear axle the propeller shaft bears a two-bladed propeller at its extremity. The pilot and mechanic occupy basket-work chairs just to the rear of the dashboard and still further to the rear is the gasoline tank on raised brackets.

Owing to the large bearing surface under the gas bag the apparatus naturally rises and descends vertically with a certain difficulty. Thus an ordinary balloon basket has been attached some distance below the engine cage, one rope going to the forward end of the frame, the other to the rear, and both passing over pulleys above the pilot's house. By these means the position of the basket can be varied sufficiently to raise or lower either the nose or the tail of the balloon and provide for ascent or descent. When sailing



Pilot and Mechanic in Malecot "Engine Room."

First Attempt of the Aeroplane Boisson-Borgries.

Ferber Aeroplane Driven by M. Legagneux.

on an even keel the basket is, of course, kept in the line of the center of gravity. This method of raising and lowering a dirigible balloon is similar to that adopted by the early sky pilots, with the difference that instead of a basket a heavy trailing rope only was employed; the method of shifting to alter the center of gravity is, however, the same.

Satisfactory trial trips were made over the Issy-les-Moulineaux ground this week and further trials are promised at an early date before a military commission interested in the balloon for army work. The claim made for this apparatus is that should the gas bag burst a gradual descent could be made.

PILOTS FOR AERIAL GORDON BENNETT.

PARIS, Aug. 27.—With the exception of one of the Belgians, all pilots have now been appointed for the Gordon Bennett balloon race to start from the suburbs of Berlin, Sunday, October 11. The list of sky pilots stands as follows: United States, Frank P. Lahm, McCoy and Forbes; England, C. S. Rolls, Prof. Huntington, John Dunville; France, Emile Carton, Jacques Faure, Alfred Leblanc; Germany, Oscar Erbsloh, Capt. Abercron and Dr. Niemeyer; Italy, Prince Borghese, Usuelli and Capt. Frassinetti; Switzerland, Dr. Beauclair.

BRITISH AIRSHIP FAIRLY SUCCESSFUL.

LONDON, Aug. 27.—The new British Army airship "Dirigible II," although a great advance upon the "Nulli Secundus," is still many years behind the French and German craft. It has been increased in size and some refinements in detail made, but there is still much to be done before a really practicable dirigible is evolved. It attained a speed of about twelve miles an hour on its trial trip, but was nearly wrecked returning to its shed.

FRENCH EIGHT-DAY TAXICAB TEST.

PARIS, Aug. 22.—A fixed course around Paris, starting from the Port Maillot, passing through Maisons-Laffitte, St. Germain and Versailles and finishing at the point of departure, has been selected for the eight-day taxicab and light delivery vehicle competition next October. The main reasons for keeping the cars on one course for eight consecutive days is to give an opportunity of more accurately controlling and comparing the consumption of the various fuels employed. In addition to a couple of days on gasoline, each competitor will have to cover the regulation distance on alcohol, white spirit and benzol, official observation being made of the quantity of each consumed. This should provide some valuable comparative figures on the cost of fuels, although alcohol can hardly be expected to give its best efficiency except in engines specially designed for its use.

By starting in the early morning and finishing at the same place in the early afternoon drivers and helpers will be able to return to their homes or business each day, a rather important consideration in view of increasing activities in the automobile trade on the approach of the shows.

Contrary to the usual plan of procedure in competitions, only one man will be allowed on each taxicab, hotel omnibus or delivery vehicle. The organizers declare that this step has been taken in order to remove the impression prevalent among business firms that two men are required to run an automobile. The plea is often put forth that mechanical traction is more costly than horse haulage because in addition to driver and delivery man there will be required a mechanic on the automobile, making three men where two are now employed. In the Paris competition all work must be done by the one man in charge of the vehicle, no outside help whatever either on the road or in the parking stations being allowed.

"Dirigible II," the New British Army Airship Making a Successful Ascent.

One of the Nearly Completed Stretches of the Long Island Motor Parkway, That Will be Used in Vanderbilt Cup Race.

KNOX ENTRIES FOR VANDERBILT—LIST REMAINS OPEN.

AMERICAN makers are beginning to wake up to the opportunities the Vanderbilt Cup race will afford for the demonstration of the speed and road qualities of their cars. A manufacturer hitherto not identified with road racing, the Knox Automobile Company of Springfield, Mass., sprang a genuine surprise this week by nominating two of its stock cars for the Long Island classic. Both are of the 1909 vintage and of the 4-cylinder type. Model M, a 48-50 horsepower machine, with 5 1-2 by 5 1-2 cylinders, is to be driven by Charles S. Basle, who scored records for H. L. Bowden at Ormond in his big Mercedes. Model O, a 38-40 horsepower car with 4 7-8 by 4 3-4 cylinders, will be piloted by William Bourque, who has been at Knox wheels in some hill-climbing contests.

The officials of the Springfield company had the speed possibilities of the Knox impressed upon them by the performances of their 1909 cars at the Wildwood, N. J., straightaway races on August 3. At this meet Knox cars won 8 out of 10 events, scoring 47 2-5 seconds for the mile, a rate of 76 miles an hour, and 28 seconds for the kilometer.

In a trial for the Lowell race, however, Basle, over a measured mile, showed the Knox "M" capable of 81 miles an hour. The nomination of the Knox pair was made on September 1, the date originally set for the closing of preliminary entries. On that day, though Chairman Thompson, of the Vanderbilt Cup Commission, announced that the double fee originally intended to be charged for entries made after September 1 up to October 1 would not be exacted and that the fee for all would remain at $1,000. This action was dictated by diplomacy and the uncertainties of the racing situation at present. The chairman realized the fact that some makers desired more time to reach a decision and others would very likely follow the example of the Knox people and compete in the race with high-powered stock cars.

On the date originally set for closing the actual paid entries were a Mercedes, a Mora, an Acme, a Chadwick, and the two Knoxes. Entries of two Locomobiles, a Thomas, and a Roebling were promised and plans were on foot for the participation of the Pope-Toledo and Frayer-Miller Vanderbilt racers of 1906. Negotiations were also in progress for a Pennsylvania. A nucleus of thirteen cars was accordingly fairly well assured, with the claim that subsequent entries likely to be made by October 1 would raise the number of contenders to at least a score.

Robert Graves has secured Emile Stricker to drive the Jenatzy Mercedes, his original Vanderbilt entry. Stricker has been a Protos pilot in the last two Grand Prix contests. He was some years ago a demonstrator in New York City for the late Alexander Fisher, at that time importer of the Rochet-Schneider. To Stricker's instructions, it will be remembered, Louis Strang attributed his success as a racing driver. The Mercedes pilot is expected to reach this country next week and will at once take up his quarters at Mr. Graves' racing garage at Mineola.

The Vanderbilt Cup Commission is scheduled to meet to-day. Mr. Vanderbilt sailed yesterday and is due to arrive early next week. Important developments are expected to follow close on the heels of his coming.

The New York Club's contest committee is making extravagant claims for its proposed race at Savannah under European rules. Its chairman seriously puts forth the statement that the entry of 15 cars by foreign makers is assured. The only actual paid entries so far seem to be three Fiats, but claims of entries promised by other importers are made and that the nominations of three Garfords, a Stearns, a Lozier, a Chadwick, an Acme, and a Pennsylvania are assured.

"If all those European racing cars are actually to be on hand," remarked an American maker, "then it strikes me that American manufacturers who send stock cars way down to Savannah with strong chances of being merely 'also rans,' are fit candidates for the easy mark class. The chances for efficient demonstration and wide publicity on a metropolitan course offered by the Vanderbilt race are so incomparably greater than the remote possibility of scoring against the foreign racers at Savannah that I marvel at an American maker hesitating for a moment in making his choice."

LOWELL'S INTERNATIONAL LABOR DAY ROAD RACE

LOWELL, MASS., Sept. 1.—Until next Monday evening this city will be the center of motoring interest in New England, and the citizens are already basking in the illumination of publicity which even their world-famous cotton mills could not bring them. It remained for the automobilists to bring Lowell into the public eye by means of the 250-mile road race which is to be held Labor Day on a ten-mile circuit in the outskirts.

When it was first proposed to hold a race the citizens were a little slow in taking to the idea, but when President John O. Heinze, Vice-President Frank S. Corlew and other officers of the Lowell Automobile Club overcame seemingly insurmountable obstacles and at last made the race a certainty, the people took up the idea with enthusiasm and they are preparing to entertain a host of visitors on Monday. Capacious grandstands have been erected to seat the spectators, and the transportation companies are preparing for the biggest rush they ever experienced.

Nine cars are now entered for the race for the Butler Ames trophy. Of these six are American and three foreign.

The domestic manufactured competitors are two Knox machines, to be driven by Charles Basle and William Bourque; two Buicks, to be driven by R. Burman and C. S. Smith; a Simplex, to be driven by Frank L. Lescault, and an American, to be driven by A. J. Andrews.

The foreign competitors are two Isottas and a Fiat. The Isottas will be in the hands of Louis Strang and Alfred Poole, two of the Isotta team in the Briarcliff race. The Fiat driver is George H. Robertson, who drove a Panhard in the Briarcliff.

Most of the machines are already on the course, arrangements having been made so that they could be used for practice early each morning. The road has been put in good condition, the corners banked and the surface oiled. About half the course is over the boulevard, where the going is fine and upon the straight-away stretches of which maximum speed can be made. The rest of the circuit is made up of good country highways and city streets. There are enough difficult places to make the race exciting and to try the best of drivers. There is a hairpin turn and several sharp right-angle turns. The whole course has been wired off and the club proposes to collect an admission fee of nearly everybody who sees the race.

The police are coöperating with the club in the patrolling of the course, and Monday there will be strong details at the most congested points. For the remainder of the course special deputies are being sworn in. There will be a telephone circuit around the course and the usual couriers and flagmen. There are no railroad crossings, and at the point where the street cars touch the course the service will be discontinued while the race is in progress.

SAN ANTONIO'S "12" WON BY STODDARD-DAYTON

SAN ANTONIO, Tex., Aug. 29.—The 12-hour endurance contest held on the fair grounds track last Saturday was won after some fast work by David Pryor's Stoddard-Dayton, with Studebaker and Mitchell as runners-up. The track was only

Stoddard-Dayton Winning the 12-Hour at San Antonio.

three-quarters of a mile long, and without banking at the corners, but good time was made and no accidents marred the day. It is believed that the twelve-hour race will become a popular form of contest, as it is almost as good a test of endurance as the 24-hour, and has the advantage that it is all run during daylight hours, rendering the lighting of the track unnecessary.

Five cars started when the gun was fired at 7 A. M. The Stoddard-Dayton, driven by De Hymel, a youth of only 18 years, took the lead at the start with a fine burst of speed, and then settled down to a regular schedule, covering lap after lap in 1:10, without varying more than two-fifths of a second. At one time he had a lead of 35 laps over the nearest competitor, but this was reduced to about nine at 5 P. M. on account of tire trouble. From then on he gradually drew ahead until at the finish he was 14 laps to the good. The Chalmers-Detroit roadster made the fastest lap, in 55 seconds, but sprung its rear axle and was withdrawn to avoid an accident after covering only 94 laps. The Studebaker put up a good race and finished only 14 laps behind the winner, in spite of the fact that it carried a touring body and had only 30 horsepower to the Stoddard's 45. The score was kept on Burroughs adding machines. Each time a car crossed the line the judges called out its number and the scorer pushed the lever of the corresponding machine. This method proved entirely satisfactory, and not the least whisper of a protest was heard. The summary follows:

Car.	Owner.	Driver.	Score.
45 h.p. Stoddard-Dayton..	David Pryor..	De Hymel....	574 laps
30 h.p. Studebaker.....	Staacke Bros.	Van Tine.....	560 "
30 h.p. Mitchell.....	D. G. Robbins	W. A. Marsh.	539 "
20 h.p. Mitchell.....	D. G. Robbins	Withdrawn*..	174 "
40 h.p. Chalmers-Detroit.	A. Calkhurst.	Withdrawn†..	94 "

*Ignition trouble. †Sprung axle.

MOTOR RACING ASSOCIATION INCORPORATES.

New York tradesmen interested in the promotion of the two-days' race meet at Brighton Beach, September 11 and 12, have incorporated the Motor Racing Association with a capital of $2,000.

The full complement of 16 starters in the 24-hour race, which is to be the star feature of the meet, seems assured. Harry S. Houpt, New York agent for the Thomas, has promised his associates to supplant the two Thomas cars ordered withdrawn by E. R. Thomas, with two machines of his own, one a stock car to be taken from the floor and the other the machine which Montague Roberts drove victoriously in last year's 24-hour race at Brighton Beach.

It transpires that two men of considerable prominence in their A. A. A. affiliations appeared among the officials on the entry blanks. One of them was Charles Jerome Edwards, president of the Long Island Automobile Club, who was named as a referee; and Charles J. Swain, of the Quaker City Motor Club, who was set down for a judge. Both are absent on pleasure or business trips. Both, on being informed of the use of their names, made haste to send declarations that they were used without authorization.

CAMERON AND BUICK IN LIGHT CAR RACE.

Two more American makes of light cars are assured of representation in the race for this class the Automobile Club of America proposes to run on the day before its contest at Savannah for big cars under European rules. A 4-cylinder Buick will be driven by Edward A. Hearne of Chicago. The Cameron Car Company of Beverly, Mass., writes that it will enter one or more air-cooled cars as it believes that for the first time in the history of competitions of this description, an opportunity is afforded "to demonstrate to the public and trade the relative merits of air- and water-cooling systems for use in light cars." There is a call for a light car race on the Vanderbilt Course, and one may be arranged.

A BUILDING LOT FOR A RACE PRIZE.

Wildwood-by-the-Sea, N. J., Sept. 1.—The Labor Day meet of the Motor Club of Wildwood will doubtless attract all the owners of fast cars in the East, who will come with the object of pulling down a neat bit of plunder in the shape of a $1,000 Wildwood Crest building lot (all improvements made), which the Race Committee has hung up as an incentive to speed.

What the Fair Autoist Now Wears

Striped Silk Rubberized Auto Coat with Auto Silk Veil.

WHILE the enthusiastic autoist never really loses interest, it is everywhere acknowledged that the real season for automobiling begins in September. And so widespread has become the active interest in automobiling throughout the country, and so numerous are the members of the gentler sex who can intelligently discuss the merits and demerits of a car, and do not hesitate to undertake a long tour through a section of country of which they know little aside from the facts that its roads are rough and its inns of uncertain quality, that it is not surprising that the question of suitable garb should have become one of vast importance. Certain it is that the woman who wishes to travel in comfort appreciates the necessity of providing herself with an outfit which will not only perfectly protect her from dust and cold, but will enable her to always present a smart, trim appearance.

For the earliest weeks of Autumn, when the days are still warm, the best sort of motoring coat is one of the rubberized taffetas or English mohairs, which are to be found in every imaginable shade and pattern, notably the wide stripes and checks now considered so smart in tailored suits. These coats are made up in various ways, although invariably long and loose, but not so roomy as to utterly disguise the lines of the figure, as was the case in the earliest models. There is, however, a marked change in the sleeves of the newest coats as compared with those made a few months ago, which it behooves every woman to carefully note. This change is due to the very radical differences between the gowns of this year and last—the Directoire influence having so marked an effect upon the sleeves of every garment that to wear anything savoring of the balloon order is to frankly announce one's self as being behind the times—from a sartorial viewpoint. This is not saying that automobile coats have tight sleeves, for that would be an absurdity that no woman of taste would tolerate. The majority of them, however, are of the modified coat order and are put into the armhole without an atom of fullness, precisely as are the sleeves of the coats worn by men. Beyond this feature and the fact that pockets are larger and more prominent than heretofore, these rubberized medium weight garments show few changes, for the satin and silk neckties worn last Spring are still in evidence and so are the contrasting satin insets on the collar and cuffs.

In the realm of cloth motoring coats, there are several fabrics employed which heretofore have not been in general use for that purpose. One of these, and a material, by the way, which is considered immensely smart abroad, is the rough-faced English tweed in London smoke gray which has almost invisible stripings of black, and another is chinchilla cloth which, while undeniably a cold-resister, is rather too weighty to appeal to some women. The cloth motoring coats are of both three-quarters and full length, and a feature of their treatment is the perfection of the tailor-finished edges and the manner in which the bulk is taken from about the hips by means of the cleverly sloped side forms. While the cloth coat, like the lighter one of mohair and silk, has double-breasted fronts, its back may be made many inches narrower and in fact many of them are almost semi-fitting, although not in the least suggesting tightness. Some of these heavy cloth coats, and especially those brought over from London and Paris, have detachable hoods and capes of the same material, so that in some climates they will do duty all winter, especially if the cape, as is often the case, is fur lined. A coat which is a compromise between cloth and fur, in that it possesses attributes of both types, is a heavy double-faced English tweed made on the conventional lines of the ulster and supplied with an exceedingly high collar lined with otter and wide cuffs of the same fur. This is an ideal garment for mid-autumn and cold evenings, as the throat and forearms—most vulnerable parts of the body—are adequately protected.

The woman who is nearly related to the owner of an automobile and yet has not the income to warrant the purchase of a varied assortment of long coats, would best purchase a practical garment of rough cheviot, which may be worn on street, railway,

New Veil in Two Sections.

English Tweed Coat.

Hip-Length Sweater.

steamer or motor. Naturally such a utility coat should not be very weighty, owing to the discomfort of walking about in it and the fatigue involved by carrying it. Nevertheless, it may be very smartly lined throughout with striped silk or satin, have one of the new deep hoods, tassel trimmed, and a detachable shoulder cape of several sections. To provide additional warmth when necessary, every woman contemplating a motoring trip should provide herself with a sweater. The latest designs in these garments are so attractive, and withal so practical, that they will instantly appeal to the woman who wishes to be garbed becomingly as well as comfortably. These auto sweaters, as they are termed, actually extend half way to the knees and cling so closely that their presence is not detected even underneath a semi-fitting coat. The daintiest of these are in white with dark brown or blue borders, which also furnish the color scheme of the turn-over collar and deep, closely-fitting cuffs.

For some occasions, such as a race meet or a hill climb in a fashionable locality, it is necessary to wear a hat of as dainty character as possible, commensurate with the sport. Many women, after long—and costly—experiments with motoring headgear, have fallen back upon the dust and rain-resisting Panama, which is also incrushable and so flexible that it may be bent wherever desired. They will continue to be worn until snow flies. Their most effective trimming consists of scarfs, ribbon chou, wheels or bows, all secured with Japanese pins, or merely fancy feather clusters.

The smartest motoring headgear is undoubtedly the visored cap which precisely matches the coat, but the most comfortable and the type much affected at this season by women who take long tours is the silk baby hood over which is tied a mask veil fitted with isinglass eyes. The double veil is now so generally used with motoring garb that almost every woman knows that it must be so arranged over the hat crown that there shall be four ends—one pair falling forward and the other backward. When these are crossed there is no possibility of the hat becoming disarranged even in the strongest wind.

TEXAS ABOUNDS IN IDEAL NATURAL MOTOR PARKWAYS

MIDLAND, Tex., Aug. 31.—It is only three years ago since Midland saw its first automobile, and now there are 41 owned here by official count, with the prospect that this number will be more than doubled by the end of the year. The majority are touring cars, and are used to carry family parties, mail, and groceries to and from the outlying ranches. "Outlying" means anything from 20 to 150 miles away from town. But who would not want to own an automobile when he can drive 98 miles over an absolutely level stretch of road without an obstruction as large as a pebble? Such is the Lone Star auto route to Seminole, Tex. This is not merely the name of a road, but of an official mail route as well. It was established September 16, 1907, and has not missed a daily trip since, which helps to explain some of the chief charms of the auto roads of this part of Texas, as they are in equally good condition the year round.

The car carries five sacks of mail a day, and Seminole now gets letters in five hours that formerly took seventeen. Other routes are to Shafter Lake, Andrews, and Monument, N. M., the first-named now geting mail within nine hours that formerly took two days. The pony express may be still an attractive feature of Buffalo Bill's show and still retain its romantic side, but it is very much out of date in this part of Texas now. Throughout the entire distance to Seminole the surface of the road is just sufficiently sandy to prevent the formation of mud after a rain, and there is not a single bog hole or creek to cause a halt. Midland has another star auto road besides the one to Seminole; it leads to Five Wells ranch, Gaines county, and is 45 miles long.

The stunts of the old pony express riders are mere child's play beside the everyday performances of R. L. Slaughter, Jr., a 16-year-old boy who sees that Uncle Sam's mail pouches are safely carried between Midland and Seminole. The trip is made once a day in each direction, consuming five hours, or an average of about twenty miles an hour. There may be no holes and no creeks, while the lack of stones is remarkable, but there are fences and a barb wire fence is not the easiest thing in the world to take an automobile through by any means. Up in the Panhandle end of Texas there are auto stages, too. One of them runs to Roswell, N. M., and it has to cross quite a few barb wire fences. To get over them, what are probably the cheapest and easiest erected bridges for the weight to be carried that can be found in this country, are built. They simply consist of two light troughs built of planks, and sloping up one side of the fence and down the other.

Young Slaughter of Midland knew of the bridge plan, but did not like it, so he invented a fence crossing of his own. At every barb wire barrier a pit, six feet deep, four feet wide and eight feet long, was dug, the pit running in the same direction as the length of the fence. Across it are laid two planks, measuring 2 by 10 inches, an upright, or flange, being nailed to the inside edge of each plank to prevent the car leaving its track. The planks are laid on the same level as the road on either side, so that there is no necessity for slowing down as is the case where the car has to climb the fence. It is a hair-raising experience to make one of these crossings at full speed. With the car going at a good 25-mile an hour gait, which is much faster than most trains run in western Texas, a barb wire fence appears dead ahead. There is no gate or passage, and one begins to wonder how the car is going to get through. Then the pit with its narrow planks looms up and even the tough-as-hide cowboy bites his cud hard and sits tight waiting for what is going to happen. A flash and the front wheels of the car are on the narrow boards, and practically before one has a chance to look down into the pit the crossing is behind and fading in the distance. It seems so easy after it is all over that the passengers think it is a good joke, but there are fifty such crossings between Midland and Seminole, and the first time he makes the trip the passenger feels worried every time he sees one of them. Although these crossings are always taken at high speed, there is no record of a car ever having been piled up a wreck in one of the pits.

The ranchman is beginning to appreciate the automobile, and dozens are now used by owners of ranches living anywhere from thirty to eighty miles from Midland, making regular trips back and forth three or four times a week. As a result, Midland now has three good garages and a fourth is in sight, while the next development will be an automobile club. Plans are now on foot for an auto stage line from Seminole to Roswell, N. M., a distance of 268 miles from Midland. Both of the towns will carry out its share of the work; 160 miles of the route are already in use, so that it is expected that autos will be running through from Midland to Roswell in a few months. After that Midland autoists will try to establish connections with Dallas and Ft. Worth.

YE SCORCHERS OF YE OLDEN TIMES.

A correspondent of the London *Times* found this entry in the records of Parliament under the date of June 10, 1816:

"The attorney general moved for leave to bring in a bill, the object of which was the protection of the lives and limbs of His Majesty's subjects by correcting the enormous abuses of stage coach drivers. Within these few days it would be hardly credible what a number of applications he had received on this subject. Some of the accounts were enough to freeze one with horror. A gentleman of veracity had informed him that on Tuesday, the 21st of May, at 5:30, the Trafalgar and Regulator coaches set off from Manchester and got to Liverpool twenty minutes after 8, doing this journey in two hours and fifty minutes at the rate of twelve miles an hour."

Doesn't it sound familiar?

THE DIRECT INJECTION OF MOTOR FUEL

By THOS. J. FAY, E. E., President Society of Automobile Engineers.

WHILE it is true the direct injection of fuel into the combustion chamber has not been favored in the past, it is something of a question if, in the course of events, this mode of the utilization of fuel may not be taken up. Irrespective of the fact of its future application, there are points of interest to be noted, and it will be advantageous to discuss them. In order that the matter may be better understood, it will be necessary to go back over the ground, as it will be remembered that carburetion was a very serious matter from the start.

Earlier attempts to employ liquid fuel were in connection with carbureters of the "lake" type, in which a pool of liquid fuel was so situated as to intercept the inflow of air, with the expectation that the air would become saturated with the hydrocarbon and thus become an explosive mixture. Expectations were realized, in a way. The air did pick up the hydrocarbon, and the mixture was to a certain extent adaptable. It was not uniform, however, nor was it possible to utilize all the liquid fuel put into the receptacle at any one time, for reasons that we now know more about.

Nature of the Distillate Was Largely Responsible.

To begin with, it will be necessary to discuss the characteristics of the fuel used, to understand why all of it was not picked up by the air as it passed over or through the fuel, as the case may have been (there were several detailed methods), on its way to the combustion chamber. The fuel exclusively used at that time was of the "olefiant" hydrocarbon series, distillates of crude oil, in fractional form. The product was delivered on a basis of specific gravity, and the lighter distillates were selected for the purpose. The lighter distillates afforded the most uniform mixture, and it was then thought that the failure to realize a uniform mixture for all the gasoline in the container was due to the failure of the vendors of the gasoline to deliver what the specifications called for.

The fundamental difficulty was overlooked, for the most part, on account of lack of knowledge of the peculiarities of the fractional distillate, and, furthermore, in consequence of the very crude nature of the devices used. It dawned upon the pioneers in the course of time that the fractional distillates of crude oil were defective for the purpose, in that the components were not all of the same degree of volatility. The more volatile portions were carried over first, during which period the carburetion was the most perfect. Then the mixture would become "leaner," and trouble would be rendered manifest.

By the time half the gasoline was vaporized the remaining portion would be so resistant as to render further action futile, and the motor would cease to perform its functions. Various designers resorted to diverse means to overcome the defect, but to no avail. It was in 1896 that the author took up the task of correcting the defects of the methods as here set down, only to find just what is here related, *i.e.*, the fault was in the gasoline, not on the basis as suspected by the then designers (failure to receive the gasoline of a specific gravity as ordered), but on a basis of difference in volatility of the components of the distillate.

Less Volatile Components Can Be Utilized.

One of the very first schemes for correcting the evil may have been the invention of "Raymond" (the author is not positive). The plan consisted in "spilling" the gasoline over a brass wire mesh, rolled up into cylindrical form, and causing the air to pass over and through the wetted wire mesh. For stationary work this scheme was the best of the time, insofar as the author can discern. The gasoline was pumped from a low to a high level and spilled over the wire mesh, while the excess ran back by gravity to the lower tank. The wire mesh was inclosed in a glass tube.

Even this scheme, as will be readily seen, failed in part, because the less volatile portions of the distillate would go by time after time, and in the end the residue piled up to a vast extent. At such a time, to remove the whole of the remaining gasoline and substitute a new supply was the only remedy. When the principle of the float-feed carbureter dawned on the minds of the engineers who were struggling with the ills of the earlier schemes it was at once to be seen that the less volatile products would be impelled with the more desirable portions into the combustion chamber. This proved to be a lasting benefit, and while the float has been done away with in certain types of carbureters, the principle remains, in that all the gasoline is passed into the motor.

It was thus proven that the less volatile products would serve as fuel were they properly handled, and in the main the value (relatively) was a matter of heat units contained in the fuel. It has been shown that the hydrogen component is of the greatest importance in the fuel, in that the increase in hydrogen rendered it possible to speed the motor, considering a given compression, because fuel rich in hydrogen possesses a low temperature of inflammation relatively to the other products of the compound. It is easy to see how hydrogen rendered the mixture easy of ignition and of a high rate of the flame propagation under conditions of bigh speed in which, unfortunately, the compression recedes.

The compression in the earlier types of motors was lower than it is to-day (1908), but the reason was well under the surface. The fuel of that time was richer in hydrogen than it is at the present time. The mixture ignited more readily and the flame propagation was more marked. Ignition troubles led to a higher compression. With higher compression the fuel problem was modified to some extent, but it is still an ever-changing bugbear. Because the fuel is not stable, either in the matter of quality or price, designs are influenced to a greater extent than one would be led to suspect.

Effect of the Height of Carbureter Float.

Liquid fuel is really delivered on a basis of its boiling point, and not with respect to its specific gravity. Volatility, then, is the measure of quality, since the calorific value does not vary very much in the several products as delivered. The difficulty likely to be experienced, in view of the method of procedure, lies in the fact that the limits of the boiling over (fractional distillate) process may not be so closely held as to assure reasonable closeness of volatility as between the components of the composition. In view of this and other facts to be disclosed lies the interest in the question of the direct injection of fuel into the combustion chamber of a hydrocarbon motor. At the present time, and just so long as the float-feed type of carbureter is used, the specific gravity of the fuel must be considered on the ground that the level of the float depends upon that very property of the fuel.

There are those who say it matters very little if the fuel stands high or low in the nozzle, since it will be sucked out anyway, and in a small degree they are justified in their belief, but it does matter if the fuel runs out of the nozzle and "floods" the carbureter. It counts primarily because it upsets the even tenor of the mixture, and it wastes fuel. The float can be set for any gravity of fuel, but it is not easy to change it from day to day, or even on rare occasions, to suit the vagaries of the fuel situation. The direct injection of fuel would obviate this trouble once for all, as the injector would be dependent upon the bulk and not upon the weight of the fuel.

It is not the intention here to elaborate upon the details of design of injectors, such as might serve the purpose of forcing liquid fuel into the combustion chamber of the motors. It will be enough to here disclose the fuel characteristics in so far as

they influence the situation in favor of the direct injection of the fuel, rather than its vaporization before use. In the first place, the fuel is not vaporized in the present types of carbureters. It is sucked out of the nozzle in a stream, and is carried along in the path of the air current, subdividing as it passes along and reaching the combustion chamber in small globules, with, perhaps, some vaporization of the more volatile products of the composition, while the less volatile portions hold to the globule formation with a good deal of tenacity.

Indeed, the suction process guarantees that the spraying phenomenon (so much desired) will not be realized, for that condition is peculiar in forcing a liquid not aspiring it. The extent to which the globules will hold to their form will depend upon the length of the intake, the pressure, temperature and time. The time is short in practice, the impelling force is barely adequate to set up the motion, and the temperature is low.

Liquid Fuel Acts as a Refrigerant.

All the conditions to be found are such as as to assure the practical absence of complete vaporization. In some designs this ideal is more nearly realized than in others. The temperature of the intake is low, for the reason that liquids in changing to the gaseous state act as refrigerants. Considering the three states of aggregation of all elements and compounds, *i.e.*, solid, liquid and gas, it must be considered that a heat exchange attends the transformation of such elements and compounds as can be changed from one to the other of the three states. Refrigerants, as the term is generally understood, are compounds, such as ammonia, carbonic acid, sulphur dioxide, etc., in which the heat exchange is attended by a considerable lowering of the sensible temperature as the liquid compound is evaporated into the gas formation. The temperature of ebullition in the case of refrigerants must at atmospheric pressure be the temperature of the surroundings, just as it is with the more volatile hydrocarbon products. Gasoline is not commercially valuable as a refrigerant for the reasons given, but it is a refrigerant nevertheless, as evidenced by the lowering of the temperature in the intake.

In mixing gasoline with air the process involves the evaporation of the gasoline; it must be deprived of its latent heat. This is not merely a matter of mingling the gasoline with the air, since the latent heat must be abstracted from the gasoline by the air before the liquid will change to the gaseous form. This takes time, of which but little is available in the interval between leaving the nozzle and entering the combustion chamber. The specific heat of air is low, and as a result the globule of gasoline must come in contact with many volumes of air before the specific capacity of the air will equal the latent heat value of the liquid gasoline. All these, and other conditions tend to thwart the good intentions of designers.

One other point to be emphasized is that gasoline as it is sucked out of the nozzle of the carbureter, made up, as it is, of hydrocarbons of differing values, from the point of view of weight and volatility, will hold to the globular form with greater or less tenacity, depending upon whether conditions are pronouncedly one way or the other. It should be noted that doubling the diameter of these globules increases their surface four times, but their bulk will be increased *eight times*. Evaporation is proportional to the surface, but if double the quantity resides under a given surface, double the time must be taken to gasify the liquid, subject to a correction in that the spheroids are reducing in diameter as the vapor expands.

Demonstrating the Action of the Nozzle.

There is no better way to find out the difference as between the nozzle performance under a vacuum and the performance of the same nozzle if pressure be applied than to watch the nozzle in a carbureter during the operation of a motor, and as against this put pressure on the same nozzle by any suitable means. With the vacuum it is a stream; with the pressure it is a spray—that is, provided the nozzle is suitably shaped. An ordinary gasoline torch has more carbureter philosophy in its humble makeup than can be found in most special devices costing overmuch and intended to prove out some theory.

With the torch it is easy enough to observe that liquid will survive the flame. All that is necessary to do to show this is to shoot the flame at some obstruction in juxtaposition. The liquid will be sprayed against the surface and the flame will not capture all of it.

The reason is, as before stated, that the latent heat of the fuel cannot be abstracted by air quickly enough to vaporize the liquid fuel, partially because the air is of low specific heat, and, again, because of the law of the sphere, in which, as before stated, eight times the volume can hide under four times the surface, if the globules be doubled in diameter.

Thus far the treatment of this subject has been, comparatively speaking, superficial, in that the future prospects are to be influenced by other and very material considerations. Hydrocarbon liquid fuels up to now have been comparatively low in cost and much more uniform in point of volatility than can be hoped for in the future. The specific gravity has been more uniform than it will be in the future. The divergence of the components in the fractional distilling process will be extended, in all probability. In other words, the limiting temperatures between which automobile gasoline will be tapped off will be wider; the product will include more of the components of the hydrocarbons. In the torch test more will shoot through the flame and land on the obstruction without taking fire at all.

This increase may be charged to a phenomenon in connection with hydrocarbon fuels that has ever been present, to at least some extent, at any rate. The time required for evaporation is not the same with all the compounds in the makeup of the fuel, and the inflammability is influenced differently with a given air dilution for the several compounds.

If, then, the several compounds are intermingled indiscriminately, it will be found that some of them will ignite readily, others with some difficulty, and more with considerably increased difficulty. The torch will show this, since the compounds that will not ignite readily will shoot through the flame and be impinged on the surface of the obstruction. Within the era of fairly uniform hydrocarbon fuels stratification was merely suspected. When the compounds entering the fuel are widely divergent there will be more than a suspicion of the presence of this undesirable phenomenon.

Essential Elements of Direct Injection.

In the chapter on "Available Fuel for Automobiles," to appear later, the time constants of the compounds in the hydrocarbons will be given a measure of attention. Here it will be enough to point out that the direct injection of fuel is not attended by the troubles so characteristic of the carbureter, for the reason that the fuel is positively pumped into the combustion chamber. There may be troubles of quite another sort to be expected, in view of the fact that nothing of moment will be entirely free from complication of some sort; there would be no place in the world for engineers without it.

In the direct injection of fuel it is apparently necessary to time the injection and carefully measure the weight of the fuel injected, in view of the quantity of air admitted. It must be borne in mind, as well, that the completeness of the combustion will be a measure of the relation of the injector (pump) to the air valve. The quick and complete combustion of the fuel cannot be effected with what may be termed "the right amount of air." There must be an excess, and unfortunately the magnitude of the excess is variable, depending upon the compounds in the fuel, their relative proportions, and the compression, assuming that the spark is properly timed. The time constant of the flame propagation is not the same for the several compounds entering into the hydrocarbon fuel. Were but one compound used, the time would only change with the *richness* of the fuel and the degree of compression, assuming a corresponding temperature due to compression.

The structural problems then will be difficult of solution if the results are to be better than those realized in the cases in-

volving correctly designed float-feed types of carbureters. It will be extremely difficult to fix the relation of the injector to the air valve; regulation for load changes will be equally a problem, and harmonizing for speed changes will be something to ponder over as well. That the direct injection of fuel will prove to be impossible is a matter that will not need second thought, for the simple reason that it is an accomplished fact, and has been for several years. None of the fuel problems can now be regarded in other than the light of refinements.

Why "Explosive Mixture" Is a Misnomer.

The great question of the future is one of high weight efficiency of the motor and high fuel efficiency, to be realized by properly supplying the fuel in conjunction with an adequate supply of atmospheric air (diluted oxygen). Indeed, it will probably never be possible to consider the use of pure oxygen in this work. Pure oxygen costs over much, and to add it directly to the fuel would be attended with danger, since the mixture then partakes of the characteristics of what may be properly termed an explosive. It is not uncommon to hear the mixture used in the internal combustion motor called an explosive mixture, but it is not properly such. Explosives are possessed of the elements necessary to their complete combustion in the absence of any outside supply of oxygen, and the rate of flame propagation is high in comparison with motor fuels. The piston of a motor cannot travel fast enough to get out of the way of an explosive mixture. This the author found out in a manner that might be termed emphatic, when some years ago it became fashionable to use B. B. DuPont powder in a cartridge inserted in a breech-lock mechanism fixed to the combustion chamber for starting, to obviate cranking, especially the larger sizes so difficult to get in motion when cold.

The scheme worked very well except in the hands of men who did not care to go through the operation twice, which became necessary on very cold mornings when the crankcase oil was of the consistency of molasses. On such occasions it was not uncommon to catch such men in the act of throwing a handful of powder into the chamber before inserting the cartridge. The plan was abandoned after a few disruptions, and especially upon being able to procure an indicator that would give a card of the curve of pressure that the blasting powder developed. Apropos of oxygen, some fuel mixtures have this element in their composition, and, in consequence, are somewhat more lively in their flame-propagating characteristics.

Fuel is relatively quick burning, but it is not an explosive in the sense that gunpowder is. Unfortunately, the fuels we are able to procure are mere mechanical mixtures of several distinct compounds of carbon and hydrogen (in the main), and each compound has its own time constant.

Bearing in mind the fact that the injector, to be as nearly perfect as possible, will have to be so designed as to supply fuel at the right time and in the right proportion, it will be necessary to discuss one more phase of the subject, a phase, in fact, beyond the pale of carbureters of the float-feed or any other known type, as they exist at the present time.

Fuels in the three states of aggregation will range as follows: (*a*) In the gaseous state they occupy the maximum space for a given mass; (*b*) in the liquid state the bulk is a minimum, differing but slightly in this respect from fuel in the solid state; (*c*) fuel in the solid state is nearly of the same bulk per pound as the liquid fuel, but the solid fuel is in more acceptable form in some respects, in that it will not evaporate, nor will it form an explosive until melted and combined with air (oxygen).

Solid fuel would be very troublesome in connection with the present types of carbureters, and it is the positive pump (injector) that would seem to lend itself to the purpose, if we are to consider solid fuel.

The latter is probably best represented by naphthalene, which is one of the aromatic hydrocarbons, and is an extract from coal tar. In naphthalene we have the nearest approach to the direct utilization of coal in the internal combustion motor. The cost of production should be very low.

It would seem to be unnecessary to point out that all the other products of the process involving the production of naphthalene from coal have a stable market, and there would be no over-production of the one or the other were naphthalene used in vast quantities in automobile motors. It is not too much to say that this fuel would quickly take the place of gasoline, at a third or less cost, were its satisfactory utilization a settled matter. The direct injection process is what holds forth the most promise in this connection, since to melt the solid fuel would be easy enough were it not for the fact that present types of carbureters demand a constant viscosity of the liquid, which could not be assured in the use of solid fuel, since maintaining a constant temperature would be very difficult.

Considering the direct injection of the fuel, it would not matter so much if the fuel were very hot or quite viscous (within limits), since the positive injection of fixed quantities would satisfy the demands; at all events, more nearly than the carbureter handles the liquid fuel of the present time. Naphthalene is especially suited to the positive injection process because of its characteristics, as high-vapor tension is pronounced. If a "fog" (very fine spray) is the ideal form of the fuel as it enters the combustion chamber, high vapor tension is the phenomenon that will assure the result.

The mixture of air with this hydrocarbon is readily ignited, according to the reports of those who have used the fuel, and the residue is not troublesome, as might be supposed in view of the high carbon content.

"Sooting" is not a feature, as it seems; nor do the polished surfaces of the cylinders show any deterioration as the result of the use of this fuel. In conclusion, then, it is plain to be seen that the direct injection of fuel offers possibilities, not only by way of a remedy for present defects, but by way of the use of a far cheaper fuel possible of supply in unlimited quantities.

SOCIETY OF AUTOMOBILE ENGINEERS TO MEET AT CLEVELAND

CLEVELAND has been set as the place for the third quarterly meeting of the Society of Automobile Engineers this year, and the dates will be Friday and Saturday, September 18 and 19. The Hollenden House will be headquarters, and the program as already outlined, will devote considerable time to visiting the numerous important automobile manufacturing plants located in Cleveland. The entire morning of the first day will be given over to this, followed by a lunch to be arranged for by the local committee, consisting of James G. Sterling, chief engineer of the F. B. Stearns Company, chairman; H. B. Anderson, of the Winton Company; F. B. Stearns, and H. W. Alden, of the Timken Roller Bearing Company, Canton, O.

The afternoon will be devoted to the business meeting and the reading of papers, discussion, and the like, and there will be a dinner in the evening, to be followed by a continuation of the technical session. On the second day a train will be taken to Akron for a visit to the Goodrich and Diamond tire plants in that city, and the visiting members will be the guests of the Diamond Rubber Company at a lunch to be given at the Akron Country Club. Following this, the trip will be made to Canton, where the society will visit the plant of the Timken Roller Bearing Axle Company's plant, and the members will be the guests of the latter company until their departure from Canton in the evening, the meeting formally ending in that city with the visit to the Timken plant.

USEFUL POINTERS FOR MAN WHO DRIVES

A CONE clutch whose leather has become glazed from use can be relcathered with a piece of belting of suitable thickness and cut to shape. The first thing to do is to measure the thickness of the old leather to the nearest thirty-second of an inch, taking the leather off for this purpose. The new leather is not likely to be required more than 1-32 of an inch thicker than the old leather, since the wear is very slight. Straighten out the old leather on a sheet of paper and measure to see what width the belt will furnish a piece of approximately the same curvature. Since the leather will stretch slightly it is not essential that the pattern of the old piece should be followed absolutely. On the other hand, if the new piece is too straight it will bulge on its smallest diameter between the rivets and will not fully release when the pedal is depressed. The new piece of belting should be carefully selected for uniform thickness throughout. The new leather is cut from it about 1-4 inch short, and is punched and countersunk at the ends for the rivets. It is then soaked in water for 3 or 4 hours, causing it to swell and soften. Meanwhile a cup-pointed rivet punch is procured, also a short square-ended rod small enough to bear against the rivet heads when they are countersunk in the leather. When the leather has finished soaking it must be applied to the clutch before it has time to dry, else its shrinkage renders it unmanageable. First one end is riveted in place, using two rivets, and the other end is brought around and temporarily held in position by rivets or wire nails. Then the opposite portion of the strip—half way between the ends—is stretched into place and marked and punched for the middle rivet. A wire nail is stuck through to hold it, and the remaining rivet holes are located and punched in the same manner. When all have been punched they are countersunk, using preferably a flat-pointed countersink made for the purpose, though a sharp pocket knife will answer. The rivet heads should be at least 1-32 inch below the surface of the leather. The leather is now riveted fast, following the same order of procedure as in locating the holes. In case the work takes longer than 1-2 hour it will be well to keep the leather wet, particularly if difficulty is experienced in stretching it sufficiently. On drying the leather will grip the clutch cone very tight. When dry it should be given a thorough soaking with neatsfoot oil, and the oil treatment should be repeated whenever the clutch gives signs of gripping too harshly.

Strange Noise and Its Cause.

A curious incident which lately befell the owner of a small four-cylinder touring car may be of interest to others. He had bought his car—a high-grade one—at second-hand after three years of service, and had personally overhauled it and put it in satisfactory condition. The engine had been found to be in good order, but as a precaution the gears, which were separately enclosed in an aluminum housing at the front of the engine, were exposed and examined. The engine was oiled by splash with two feeds to the crankcase and one to the governor case—enclosing the gears—from a combination mechanical and sight-feed oiler. The oiler frequently failed to pump, and the crankcase was then fed by a hand pump, and melted grease and oil were injected occasionally into the governor case by disconnecting the oil pipe. One day while the owner was visiting friends some miles from his home an ominous noise developed about the engine. It came and went in pulsations, which became more prononnced when the throttle was opened; and it was neither a grind nor a scrape, though it strongly suggested both. It seemed to come from the front part of the engine, and the fan and fan shaft ball bearings were investigated without result. The power did not seem to be affected, and the only conjecture the owner could make was that one of the gears he had recently examined had slipped endwise on its shaft and was grinding away at the aluminum casing. There was no immediate opportunity to examine the gears, and a 40-mile spin was taken with the friends aforesaid. Before the 40 miles were over the noise had become almost continuous and was alarmingly increased in volume; and the owner drew a long breath of relief when the ride had ended without sudden casualty. On depositing his friends he took the car at once to a garage, and, aided by a helper, dismounted the headlights, front mud guards, radiator and radiator cradle in order to gain access to the plate covering the gears. To remove the cradle from the frame it was necessary to slacken the two lateral bolts holding the front side arms of the crankcase to the side members of the frame. This permitted the frame members to be sprung apart sufficiently to release the cradle. At this point it was discovered that the left hand front engine-to-frame bolt was already loose. The space inside the channel was filled by an aluminum casting which met the crankcase arm. The reaction from the explosions produced a lifting action at this point which overcame the weight of the engine, and the aluminum casting was itself free to shake. It was instantly suspected that here was the cause for the noise. Nevertheless, the gears were exposed and examined to make assurance doubly sure, and, as anticipated, they were found in perfect condition. On reassembling the parts with the bolts properly tightened, the noise was banished. If the true origin of it had been suspected at the outset it could have been corrected in three minutes. It must not be inferred from this that a loose engine-to-frame bolt will always result in such disquieting symptoms as those just described. If the aluminum casting had been a snug fit in the frame most of the noise would have been prevented, and the bolt might have broken off before the much less audible thumping of the crankcase arm on the frame had been traced to its real cause. Cases have been reported of small two-cylinder engines, suspended crosswise at the front of the car, shearing their frame bolts nearly through or breaking them off entirely before the owner suspected anything wrong.

Care of Sprocket Chains.

It is rather common, especially in cars with planetary gear chain transmission, to see the sprocket chains drenched with oil and thickly covered with dirt. The oil itself is naturally not objectionable, but the dirt draws the oil as fast as it gathers, and, since the oil causes it to cling, it abrades the teeth of the sprocket wheels. It must be admitted that the proper treatment of sprocket chains is less easy than slushing them with oil. As outlined by the chain makers and motor car manufacturers, it is to detach the chain, say once in 500 miles—oftener would be better—soak it for several hours in kerosene and wipe as clean as possible; then boil it in mutton tallow to which a liberal supply of graphite has been added. When the chain is taken out after the tallow has had ample time to enter every crevice, it is wiped as clean as possible, so that it will not catch the dust more than can be helped. It is then brushed clean at the end of every day's run. The brushing process calls for a jack, but if the right kind of a brush is used it need not take more than a few moments. A convenient brush may be made by wiring three bicycle chain brushes side by side.

A Case of Overheating.

A 30-horsepower four-cylinder touring car once developed a stubborn case of overheating which puzzled the owner for several weeks. The pump was inspected and found in good order; the carbureter was readjusted and the fan belt tightened, but still the overheating persisted. Finally the cause was discovered in the gaskets between the water pipes and the cylinder castings, which had melted and spread until they nearly closed up the openings. A few minutes' work with a sharp knife settled the trouble for once and all.

LETTERS INTERESTING AND INSTRUCTIVE

IS THE PRIVATE PIT ADVISABLE?

Editor THE AUTOMOBILE:

[1,525.]—Being possessed of mors than the average run of mechanical sbility, and contemplating the erection of a private garags where I can house and take care of my own car, I would like to know if you consider a pit an essential part of such a building. My mechanical knowledge has been gained in lines other than that of automobils repairing, and while in the early days the sight of a driver lying underneath hie car was quite a frequent one, I must say it is something that I have not noticed now for a long while. I do not know whether this is altogether on account of the automobiles having been improved to such an extent that similar attention is no longer necessary, or whether the development has only progressed to a point where this can be given in a garage, and this is the reason why it is no longer done on the street. In your opinion, would a pit justify the expense entailed in making it.

Mt. Vernon, N. Y. ENGINEER.

We should say that the construction of a pit merely to take care of such repairs of this kind as would be necessary on a single car, would be a needless expense. Even where it is the owner's intention to effect repairs of every kind within his ability to handle with the facilities available in a small private repair shop, the construction of a substitute for a pit is so easy and so much more economical as to place the latter out of the question. The frequent necessity for lying down in the mud beneath the car in former days was largely due to the fact that American designers favored the horizontal type of motor and many of its essentials could not be conveniently reached in any other way, though probably it is somewhat of a misnomer to use the word convenient where crawling beneath a car is concerned. The placing of the motor forward, and the tendency toward a unit type of design in which the gear-set is either a part of the motor unit, or is combined with the rear axle has made the occasions on which it is necessary to get beneath the car so rare, that nowadays neither a pit nor a substitute is considered essential. In case of a repair to the propeller shaft, it would be easier to remove the body of the car.

INFORMATION WANTED ABOUT BELT DRIVES.

Editor THE AUTOMOBILE:

[1,526.]—Can you tell if bslts have ever been employed on automobiles for the transmission of the power, and if not, why such a method is not perfsctly feasible. Belting is employed for driving machinery under the most esvere conditions, out of doors as well as under cover, and as the belting on an auto could easily be protected, as is most of the machinery now, there seems to be no reason why it should not be a practical solution of the problem of transmission. INVENTOR.

Philadelphia, Pa.

Belts have been used on the automobile, and usually to the sorrow of its driver. The German Benz cars back in the Nineties, had a belt transmission, and not a few others have followed the example of these pioneers, only to give up the use of anything so frail and uncertain as leather and canvas for the transmission of the power under conditions which cannot be approached by any other form of service for severity. True, motorcycles still employ belts to transmit the power in a number of different types, but, in our opinion, this is the weakest part of machines of that class, and they would be far better off with a chain. In fact, the tendency throughout engineering practice is to do away with the belt altogether wherever it can be dispensed with, and machines that cannot conveniently be directly connected to the source of power, are now very largely chain-driven. The latter is positive and at the same time permits of a certain amount of flexibility through the looseness of the chain. There is no good reason why a transmission using chains altogether to give the different speeds would not be feasible, particularly where a chain of the "silent" type, such as the Renold, is employed, but in the light of present design, it would be far from being a practical and commercial success, as the tendency is almost entirely to the shaft-driven type of car.

A BRIEF FOR THE THREE-CYLINDER.

Editor THE AUTOMOBILE:

[1,527.]—Your answer to Mr. Ellis, on page 229, issue of "The Automobile" of August 13, does not seem to me to accord with the facts. The customary three-cylinder engine has its cranks at 120 degrees apart, and this is an even spacing, and therefore just as well balanced as can be. It can be shown both by trial and mathematically that when there are two pistons moving in one direction they are moving slower than the third and so are balanced by it. The power impulses follow each other in regular sequence and are thus balanced. The only thing not balanced worthy of mention is the movement of the whole engine in its plane due to the flywheel being by one end only. This is somewhat more perceptible than with a two-cylinder and cannot be partly overcome by having two pistons at the ends move together as it is partly overcome in a four-cylinder.

With pistons of decent weight, this movement is negligible and even in a light vehicle, the three-cylinder engine can serve so well that it is impossible to tell whether it is a three or four-cylinder by the feel of the riding. And this is the final test. Of course, if a buyer wants the biggest thing on the street, he is not satisfied with three cylinders, but must have six or eight; not that these numbers are appreciably better than five or seven, but that he may have more than common. And why he should stop at eight I do not see. If there is virtue in quantity, why not go to the limit? Ten will run more smoothly than six and no flywheel is needed. And think of the long bonnet needed to cover ten cylinders. It could be used for a bedroom in a pinch.

But if a man wants the golden mean that gives the maximum advantage with the minimum complication and cost, it seems to me he must stay nearer to a sane number of cylinders. The success which the one-lungers have given is too well-known to be lost sight of. But the single cylinder does not balance, and this is its objectionable feature. We must have at least two. If four cycle, they must be opposed to both balance the pistons and impulses and the opposed engine has some objections, so the next number is the three-cylinder. This is the least number that balances the parts and explosions and it has all the advantages of compactness and suitability that the four-cylinder has. It is slightly less steady but it has one set of parts less. The reduction in number of parts is far greater than the loss in steadiness of running.

This will readily be understood by comparing a few engines. The single-cylinder of a given power gets but one impulse in two revolutions. It is the maximum of simplicity and vibration. Two cylinders for the same power balance each other, thus wiping out that source of vibration and dividing the impulses by two, both as to size and time, so that the vibration therefrom is but one-fourth as great as with the single-cylinder. Thus doubling the parts decreases the vibration by more than 75 per cent. This is a gain worth while. When we add another cylinder we get balanced parts as before, so there is no gain there, but we get three impulses of 1-3 the power in a given time and so each is but about 1-9 the original effect.

This is more than cutting them in two and with the other advantages of the multiple cylinder form, such as simple piping, juxtaposition of plugs, single camshaft and similar reasons, is sufficient to pay for increasing the number of cylinders to three. But the four-cylinder engine gains nothing except a slightly better balance. The difference between 1-9 of a given shock and 1-16 is so slight that the average rider cannot tell it with certainty and so it is negligible; but the difference betwsen keeping three and four cylinders in order, oil and spark is 1-3 and the cost is more than the gain. This is why I believe in three cylinders for four-cycle engines and two cylinders for two cycles. These numbers are the least that will give the multiple cylinder effects. I have never seen a three-cylinder motor with 180-degree shaft except in compound form. Six-cylinder engines are simply two threes, so there is nothing wrong with 120-degree shafts. CHARLES E. DURYEA.

Reading, Pa.

We cannot say that we have ever seen a three-cylinder, four-cycle engine that had its crank pins placed, two in one plane and the third 180 degrees away, but our statement in the reply to the letter in question, was to the effect that regardless of whether the cranks were spaced equally round the circle as in the 120-degree arrangement, or as just mentioned, the impulse balance was far from being as good as could be obtained with the four-cylinder engine. This, we think, is in accord with the facts, and are further of the opinion that it is borne out by your own letter, in which you state that the difference between 1-9 and 1-16 is negligible, the latter representing the decrease in

vibration brought about by the addition of an extra cylinder. In view of the high compression and high speed now currently employed in automobile motors, it strikes us that this matter of more than 40 per cent. difference is quite the reverse of negligible. In fact, to regard it as such is almost on a par with an alleged automobile designer who is said to have marked the representation of a hole on a drawing "nearly 3-8 inch." Trying to make a good fit of a 7-16-inch bolt in that hole would appear to be about equivalent to stating that a difference of 40 per cent. or more in the vibration was a negligible quantity. Of course, the actual quantity itself is small, and stating it in percentages is frequently misleading. Further than that, the fact that a jury has convicted a man of a crime does not mean that he may have been actually guilty of it; merely that they think him so. Thus the great number of users of four-cylinder motors may not actually mean that it is so far superior to the three-cylinder that the latter has been forgotten completely, but merely that they think it is. But the thinking so seems to be equally effective in both cases.

WHAT ARE THE DRAWBACKS OF CONE CLUTCHES?

Editor THE AUTOMOBILE:

[1,528.]—I have noticed that during the past three or four years there has been a constant tendency away from the old conical type of clutch with its leather facing, and in favor of the multiple-disc type. However, this seems to have been largely the case, at any rate as far as my observation extends, with new makers in the field, and with old-established makers where they brought out new models. Despite this general tendency, for it certainly does seem to be very general, some of the most prominent makers still stick to the cone clutch, so it seems to me that there must be something more than the reasons which appear on the surface for its retention in one case, and its abandonment in favor of the multiple-disc type in the other, particularly as the later type of clutch is much more expensive to build, although the later fact does not appear to prevent its adoption on low-priced cars.

By way of enlightenment, both for myself and doubtless a great many others who are equally interested, will you briefly sum up the good and bad points of the leather-faced cone clutch? I have driven a car equipped in this manner for three years now and I have had very little occasion to find any fault with it, nor have I had to go through the long list of ills that so many of your correspondents detail concerning their experience with their cone clutches.

FRICTION.

Toronto, Ont.

As was the case with practically every other essential of the automobile of early days, many mistakes were made in the design of the first cone clutches, so that their refusal to work satisfactorily was not the result of there being an inherent defect in the principle, but lay almost entirely in their design. We say "almost entirely," because a development that has since come into existence has had a great deal to do with the improvement of the cone clutch since, and that is the cork insert. Many of these early clutches were designed with an improper angle of contact, then again, the spring pressure was insufficient, or in the case of a clutch of large diameter, improperly applied, though the most prolific source of trouble was the manner in which the clutch was mounted on the car.

Frequently, the side members of the frame were depended upon to some extent to preserve the alignment of the motor, clutch and gear-set, and where insufficient means were employed to permit the clutch to center itself in the flywheel automatically, regardless of its relation to the gear-set, it was not to be wondered at that trouble followed after the car had been in use a comparatively short time, as the frame either received a whack that put it out of true, or it sagged sufficient to give rise to ills that were nearly always traced to something else. Needless to add, the correction of the latter did not in turn correct the ill.

Given the correct angle of contact, a proper mounting that will permit the clutch to center itself in the female member regardless of its relation to the other essentials of the transmission, the leather-faced cone clutch will be found very satisfactory, and it can readily be made of such small diameter and of such weight that its inertia will not interfere with gear-changing. Another source of trouble on early cars, was the leakage of leakage of lubricating oil out of the crankcase, and this found its way along the crankshaft and onto the facing of the clutch where it naturally destroyed the friction properties of the leather against the cast-iron and caused such an amount of slipping that the clutch often became virtually useless from this cause. This gave rise to the use of numerous applications, such as rosin, talc, fuller's earth and the like, which, of course, were nothing more than makeshifts. Better design has served to eliminate this source of trouble to a very large extent, while the adoption of cork inserts, the coefficient of friction of which is not influenced by oil, did away with it entirely, beside effecting a vast improvement in the conical type of clutch as a whole. This, together with the fact that their clutches were probably better designed in the first place than many of the others, accounts for the retention of the conical type by some of the best known American makers.

But there has been another factor at work, where the adoption of the multiple disc type of clutch is concerned, and that is that it can be said to merit the term of "fool-proofness" to a much greater extent than any other, and, moreover, it does not require anything like as much skill to handle it properly as does the cone clutch. In other words, it takes a better driver to handle a car with a cone clutch than one with a multiple disc, especially at the outset, before the peculiarities of the car are known by the driver. The ability to run a multiple disc cutch constantly in oil is another factor of great importance in its favor, and as the discs may be made of small diameter and very light, the inertia effects are reduced to a minimum.

WHAT IS THE CAUSE OF THIS DRIPPING?

Editor THE AUTOMOBILE:

[1,529.]—I have a Rapid car and have been having considerable trouble with my carbureter, which will drip constantly after the engine is stopped. I have lowered the float and finally bought another carbureter of the same make, but with the same results. The system is of the float-feed type. If any of your readers can help me out, I will appreciate it very much, as the dripping is not alone wasteful, but is also dangerous. WALTER WALDIN.

Miami, Fla.

As you do not say just where the gasoline drips from, nor how long it continues after the engine has stopped, any diagnosis that we can make of the trouble can be nothing more definite than a conjecture. It may be due to capillary action, the level of the gasoline in the float chamber being so close to the opening of the nozzle that this goes on steadily, or it may be due to a poor adjustment of the carbureter, the engine getting a mixture more or less rich in liquid gasoline, which, while the motor is running, is consumed, but once it is stopped the amount that has collected in the manifold begins to collect and drip out. Lowering the float should prevent the former, while a correct adjustment of the needle valve to suit the demands of the motor for fuel should avoid the latter cause. It is quite probable that the trouble is due to neither of these, and if any of our readers have had a similar experience which puzzled them to the extent of investing in a second carburcter, they are quite welcome to explain the cause and the remedy they adopted, in these columns.

CONCERNING THE MILE CIRCULAR TRACK RECORD.

Editor THE AUTOMOBILE:

[1,530.]—I have seen lately in two different newspapers where Barney Oldfield made a mile in :29 on a circular track. This was made on a southern track, at Louisville, Kentucky, I believe. Traveling a mile in twenty-nine seconds is going faster than 120 miles per hour; this would be remarkable on a straightaway, but, as it said, this was on a circular track. This seems incredible to me, but to settle an argument I write you. What is Oldfield's fastest mile on a circular track? FRED E. PETTIT, JR.

Peabody, Kansas.

This was evidently a misprint and intended for :59. Oldfield's best time for one mile on a circular track is :53 flat, and in view of the poor nature of the ground on most of the horse tracks, it is probably pretty hard to better this. It is not, however, the mile record, which was made by Christie in one of his front driven machines at St. Paul last year. This is 52 seconds.

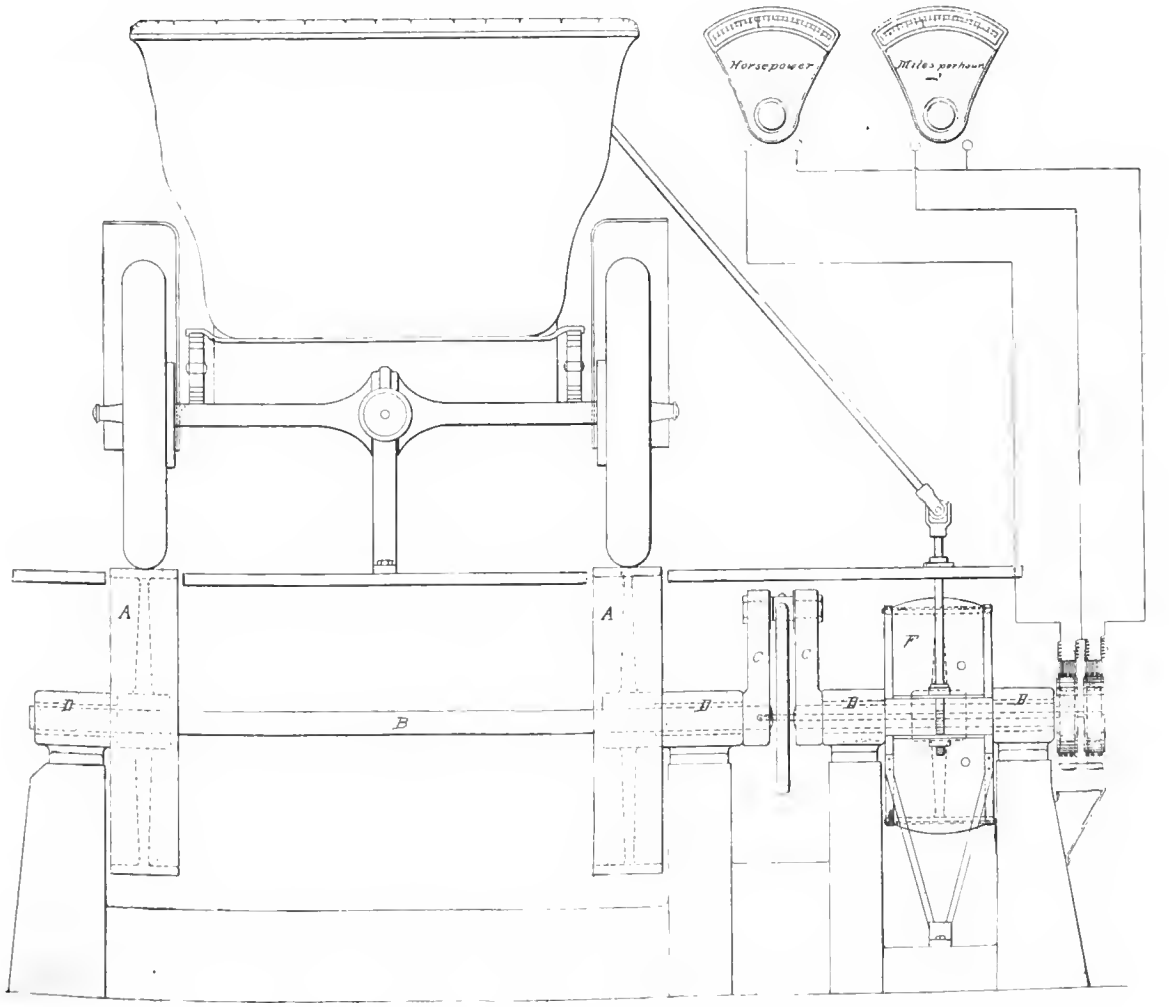
A DIRECT READING AUTOMOBILE POWER METER

By PROF. J. W. ESTERLINE, Purdue University.

PROF. C. R. MOORE of Purdue University and J. Harris, of the Central Laboratory Supply Company, of Lafayette, Ind., have developed and patented a power and speed indicator, especially adapted for use in testing automobiles, which is unique in the fact that it indicates directly on a scale, without any calculations whatever, the horsepower developed at any speed and the speed in miles per hour. This instrument should be useful to manufacturers as a convenient method of testing the driving power of a finished machine, the test being easily and quickly made, without any changes being necessary in the automobile to prepare it. Such a method should be especially desirable in winter and when the roads are bad, and it has the further advantage that all parts of the machine are easily inspected during the test, as the automobile remains stationary. Salesrooms and garages will find it of value in demonstrating the power and speed of machines, as well as to test those which have undergone repairs. Members of automobile clubs will take interest in comparing machines, and in making power and speed tests for themselves.

The rear wheels of the automobile to be tested are run upon two wheels (*A* -*A* in the drawing) spaced to correspond to the tread, and mounted on a shaft *B* beneath the floor. The front wheels are blocked, and the machine securely locked to a post in the rear. When the automobile is started, it itself cannot move, but it drives the two wheels *A*. To place a load on the engine an absorption brake *F* is connected to the end of the shaft. The power required to drive the brake is changed or adjusted by means of a hand wheel within reach of the operator.

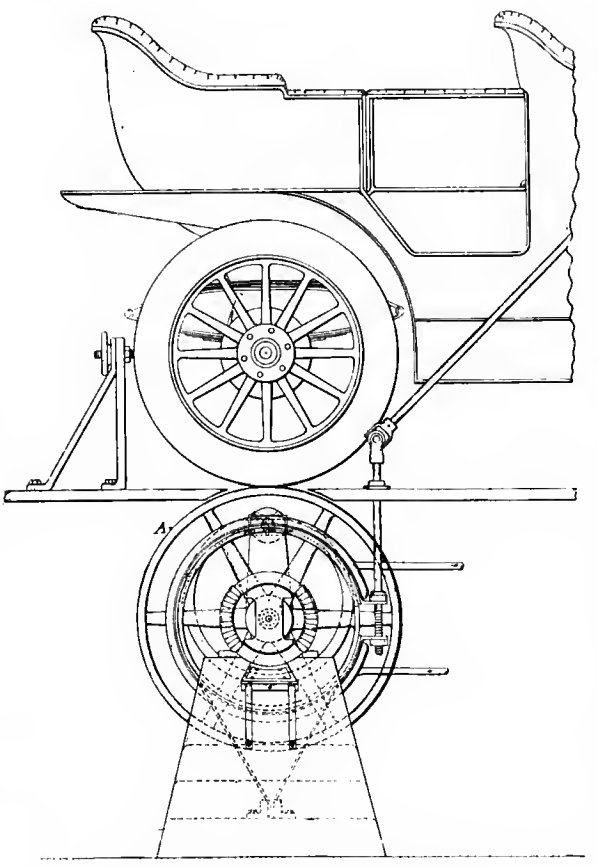
The ingenious part of the apparatus is the device which indicates the power. It is comparatively easy to make a power indicator which will show the power correctly at one speed, but to produce an instrument which will indicate the power delivered by the engine at any speed, is not so simple a matter. The power meter *E* is connected between the shaft *B* and the spindle of the brake. It consists of two discs *C*, one fastened to the shaft *B*, the other to the shaft of the brake, and connected by a spring. All of the power developed by the automobile is transmitted to the wheels *A* and the shaft *B*, then through this spring to the brake. The spring is designed so that twice the sine of half the angle of deflection is proportional to the torque de-



Sectional View Showing Elevation of the Moore-Harris Direct Reading Electrical Power Meter.

flecting it. When the brake is applied the spring is deflected by the power transmitted through it.

Connecting to each of the discs *C* is a small revolving field alternating current generator. The generators are exactly similar, and produce sine waves of voltage at the same potential. It is well known that when two alternating currents of the same voltage and wave form are directly opposed to each other no current will flow, but if the alternating waves are displaced, then a current will flow proportional to twice the sine of one-half the angle of displacement. The two generators are connected in opposition and so placed that they exactly oppose each other when there is no deflection of the spring between the discs *C*. A voltmeter is placed in the circuit between the two small generators. When no power is transmitted there is no deflection of



Side Elevation of Moore-Harris Power Meter.

the spring and no current flows, consequently the voltmeter reads zero. When power is transmitted by the spring it is deflected, and the two alternators are thrown out of step by an amount equal to the deflection of the spring. The torque is proportional to twice the sine of one-half the angle of deflection of the spring. Also the current through the voltmeter is proportional to twice the sine of half the angle of displacement of the two alternating currents, which is also the deflection of the spring, so that the current through the voltmeter at a given speed is directly proportional to the torque.

The horsepower transmitted is proportional to the torque multiplied by the speed. Likewise the voltage of the little generators also changes with the speed as well as with the deflection of the spring, so that increasing either the speed or the torque will increase the reading correspondingly. Therefore, the voltmeter gives a reading proportional to the product of the speed and the torque, *i.e.*, it reads the horsepower transmitted. The voltmeter, of course, is calibrated in terms of horsepower inst of volts. This is the only instrument of the kind which been devised to read horsepower directly on a scale without mathematical calculations whatever.

Further than this, since the voltage of either of the alternat alone is proportional to the speed, by connecting one of tl directly to a second voltmeter, the revolutions per minute miles per hour can be read off the scale.

The shaft, wheels, brake, etc., are all placed beneath the fl so as to be out of the way. The instruments for reading ho power and speed can be placed on a table or mounted on wall. The use of revolving field alternators for indicating displacement of the spring does away entirely with conta brushes and moving electrical connections, which makes the paratus reliable and unlikely to get out of order. The ma facturers, the Central Laboratory Supply Company, of Lafay Ind., also furnish recording voltmeters, which may be used inst of or in connection with indicating instruments, so that a comp record of the test is made. The range of the power meter ca quickly changed by removing the spring and inserting anothe greater or less strength. The brake is supplied with an att ment so that if need be the spring can be quickly calibrated. of the springs sent out with the instrument are standardi so that this is seldom necessary.

The use of the power meter is not limited to automobile t ing, as it is being applied to the testing of gas and gasc engines, steam engines, machine tools, dynamos and mot However, its application to the urgent needs of the automc field is timely, and it will doubtless prove to be a useful adj to the manufacturing plant and the salesroom.

THE INTERNATIONAL ROAD CONGRESS.

The program of the International Road Congress w will be held in Paris during the coming October, has just l sent out. The Congress will open with a reception on the 1 on the 12th there will be a full meeting at the Sorbonne, lowed by the opening of the exhibition in the Tuileries Gard the various sections will meet on the morning of the 13th in the afternoon the delegates will visit places of interest Paris. For the rest of the meeting the program reads: O ber 14, excursion to Versailles; October 15, meetings of secti October 16, excursion to Fontainebleau; October 17, clo meeting; October 18 to 20, excursion to Nice and vicir October 21, visit to Monte Carlo.

The Congress will be divided into eight sections and altoge ninety-nine papers will be read, France contributing thirty-se Great Britain seventeen, Belgium fifteen, Germany twelve, United States eight, Holland three, Austria and Switzerland two, and Italy, Portugal and Russia each one. The subj which will be considered include the materials used in road struction, means of preventing wear and dust, effects of a mobile traffic, watering and oiling and signs indicating dista and dangerous turns and grades. Not only the wear and caused by automobiles on the roads but also the effects various kinds of roads on automobiles and tires will be cussed, the Hon. C. S. Rolls being down on the program a paper on the latter subject. Another paper will be read Dr. H. S. Hele-Shaw, the inventor of the multiple-disc clu The American delegates will go under special instructions f President Roosevelt, whom they visited recently at Oyster The President expressed the liveliest interest in the work the Congress, and hoped that it would be made permanent.

Emperor William has once again expressed his desire see the proposed Taunus track take on more tangible form has pointed out the gratifying financial results achieved at Die as a spur to the parties lagging with their decision. It is na ally only a question of money, and the city of Frankfort ca quite see its way to take up the heavy obligations connected the scheme.

LOZIERS for 1909 In Two Models

Lozier Four-cylinder, Seven-passenger Touring Model for 1909.

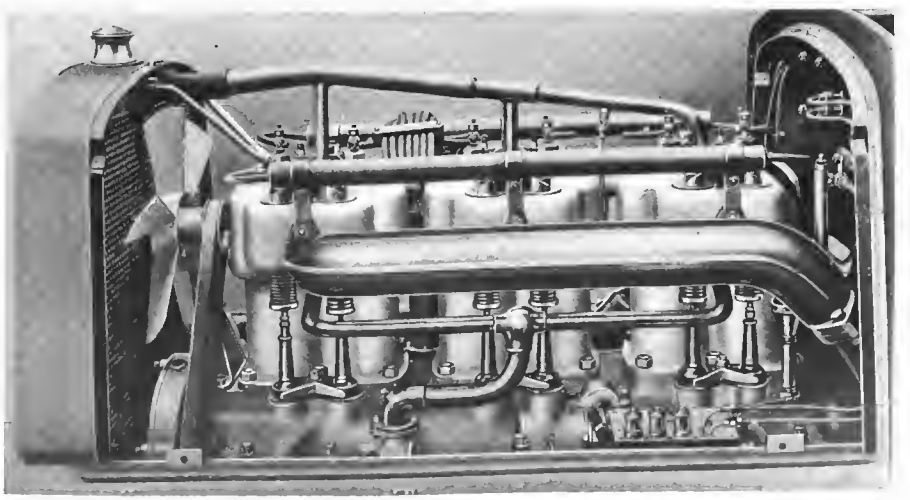
WITH the passing of the season of 1908 the double side-chain drive ceased to be a factor in the Lozier construction, as the announcement of the Lozier Motor Company, Plattsburg, N. Y., for 1909 is to the effect that there will be but two Lozier models for the coming season, and both of them will be shaft-driven. As a matter of fact, both of these models have been on sale since July 1, and a number of them are already in the hands of new owners. Both are standard chassis, on which runabout, touring, limousine, or landaulet bodies will be mounted, the difference being that one is a four-cylinder model and the other a six, the motor of the latter being shown by one of the accompanying illustrations. The cylinders of both models are cast in pairs and finished in the manner that has long characterized the Lozier motor, *i.e.*, a pearl-gray baked enamel. Large covers are employed instead of making the water jackets almost entirely closed, thus affording easy access.

The engine base is of aluminum alloy, and is cast integral, with supporting arms and bed-plate extending to the side members of the frame, which are considerably narrowed, thus giving an unusually short turning radius for a large car. A cast-aluminum oil-pan completes the crankcase, and may readily be dropped to permit of inspecting the crankshaft or its bearing, the matter of doing this being strikingly illustrated by one of the photographs. The cylinder dimensions of the four-cylinder motor are 5 1-4 inches "square," while the six-cylinder dimensions are 4 5-8 by 5 1-2 inches, the motors being rated at 45 and 50 horsepower, respectively, according to the A. L. A. M. formula.

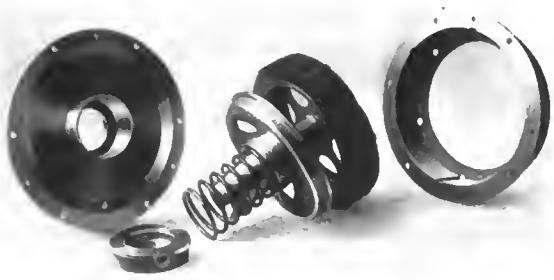
Valve disposition is of the outboard port type, two camshafts placed on opposite sides of the motor and inside of the crank case being employed. These shafts are made of one piece, with the cams integral, and are of special steel, which is subjected to a heat-treating process and ground on the cam faces to .001-inch. The valves themselves are of nickel alloy and are operated on the direct thrust plan, the valve springs being seated at their lower ends in cup lifters, thus insuring uniform downward push in seating the valve. The valve-lifter housings are fastened to the aluminum motor sub-base by means of yokes.

One of the most striking features of the 1909 Lozier cars is to be found in their crankshafts. These are forged from a chrome-nickel steel of the grade employed for armor-piercing projectiles, and each shaft is heat-treated, hardened and ground. In the case of the four-cylinder motor it is supported on four annular ball-bearings with very large balls, running between extra wide, hardened straps. The remarkably high elastic limit of this crankshaft will be understood when it is claimed that when supported at the ends it will stand a dead load of 17 1-2 tons without permanent deflection, and it is due to this fact, and to the liberal size of the ball-bearings, that in the 1908 season there is not a case on record of a broken ball or loose crankshaft bearing, say the makers.

The entire lubrication is by splash, which is made possible by the universal use of ball-bearings in the camshaft, crankshaft, clutch, and all magneto and pump-drive bearings. The main reservoir, which is suspended from the chassis, contains three gallons. The working oiler occupies the space between the motor base and the frame, and contains four metallic piston pumps of the McCord type, the master pump drawing oil from the main reservoir to the working oiler, the next two throwing oil to the crankcase, and the fourth being merely a tell-tale, delivering oil to a single sight-feed on the dash, whence it returns to the reservoir. In the case of the six-cylinder motors an additional plunger pump supplies oil to the base of the third pair of cylinders. This system discards entirely the multiplicity of oil pipes usually found running to various plain bearings. The connecting rod lower bearings being, of course, of the plain white bronze type, are lubricated by a special U-section ring oiler, which receives oil from the splash and by centrifugal force



Off Side of Six-cylinder Lozier Motor, Showing Oiler and Pump.



Components of Lozier Multiple Disc Clutch.

delivers it through interior channels in the crankshaft direct to the bearings. The pet cocks in the base and in the lower portion of the oil pan enable all the oil to be drawn off, while gauge cocks enable the proper level to be determined.

The carbureter is of the central-draft, float-feed, compensating type, with automatic auxiliary air intakes. An especially valuable feature of the carbureter is a variable needle valve, the needle valve orifice opening automatically with an increase in the speed of the motor. A new feature is a butterfly valve connected to a rod projecting through the radiator near the starting handle, to increase the air draft when starting a cold motor. The needle valve is located directly in the center of the float chamber, insuring a uniform gasoline level on the heaviest grades. The double ignition system, first introduced on the Lozier cars in 1904, is still employed without change—the Bosch high-tension magneto, as in the past, being the standard source of electrical energy, the magneto plugs being located in the valve covers on the inlet side. The auxiliary system consists of a high-tension storage battery of 50-ampere-hour capacity.

The cooler is of the well-known Lozier design, containing 2,000 copper tubes. The retention of this type of radiator, while expensive, is compensated for by the manner of easy cleaning with a brush, and in case of damage to the radiator temporary repairs may be satisfactorily made by simply inserting corks in any of the damaged tubes.

Control is by means of the regulation spark lever and hand throttle on a stationary steering-wheel quadrant, the throttle being interconnected with a foot accelerator. The hydraulic governor has been discarded, as the other controls have been found to be all that is necessary.

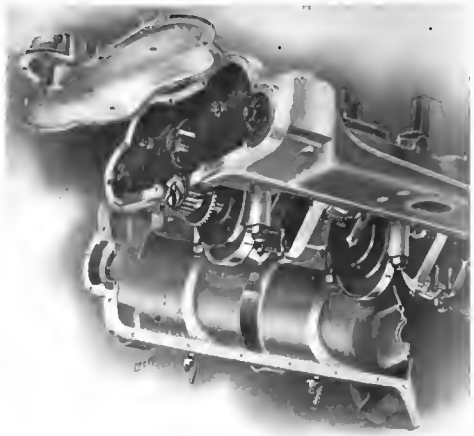
A special feature of the clutch is the fact that it is mounted on annular ball-bearings. It is of the multiple-disc type, containing 33 hardened and ground discs of saw-blade steel enclosed and running in an oil-tight case. The clutch may be slipped indefinitely without danger of over-heating or wear, enabling the car, when desired, to be started from a dead standstill on the high gear. Clutches that have been in use for

Two Views of the Rear Axle Driving Unit.

12,000 miles last season show no perceptible wear o

The clutch pedal is interconnected with the shi locking the gears when the clutch is in place. Thr for by a ball-bearing plate. The connections between shaft stub and the forward end of the drive shaft is by universal joint, consisting of an internal a gear. A special feature of the Lozier car, adopted improved for 1909, is a clutch brake, retarding the tion of the gears and tending to facilitate gear-shift

The gear-set, of the selective type—the standard of the Lozier since 1906—has four forward speeds ; all shifts being made with one lever, third speed ge direct with no gears whatever in mesh. The fou through gears having a ratio of 2 1-2 to 1. The insp on the top of the case is removed by means of wing bolts of which are connected at the lower end by hir they may be dropped out of the way without entire the nuts. A threaded hand-hole plate allows of case with oil without removing the entire top plate and gear-shafts are cut from chrome-nickel steel a on annular ball-bearings. The gears are hardened



Accessibility of the Timing Gears and Main B

nace and pyrometer, and as there has been no case gear in 1908, this method of cutting and temperi mains unchanged.

Details of Shaft-drive Construction.

The propeller shaft of chrome-nickel steel is at angle to the horizontal, and in last year's cars the was dispensed with—a distinct advance in cardan struction. The torsion member now consists of a ing bolted through to the differential case housin the forward end in a sliding sleeve joint with bal member transferring the torsion to a cross-fra The differential is of the bevel type, large and an main drive bevels are unusually large. The final the floating type, the driving shafts being mount pendent annular ball-bearings. As the differential gears are supported on their own ball-bearings, the may be removed independently.

The frame is of the drop type, to get ample sprin clearance and low center of gravity, and is unusua in front to insure small turning radius. The midd very deep, and tapers at both ends. Special cr carry the cooler and grease. The steering gear Lozier construction, all parts being very large; th inclined 45 degrees from vertical. The cross link back of the front axle, and all connecting links socket adjustable joints. All wheels are 36-inch, and 4 1-2-inch rear tires. The wheelbase of the 4 four-cylinder car is 124 inches, the six-cylinder 131

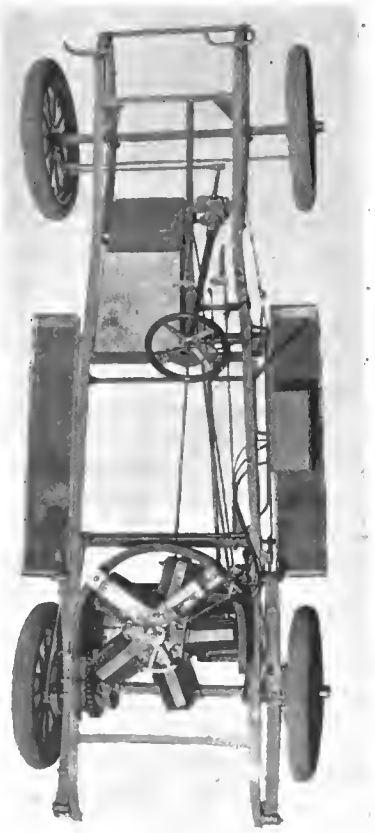
Adams-Farwell 1909 Model Nine

The Adams-Farwell Four-passenger Roadster, Showing High Road Clearance.

IN the 1909 Model Nine Adams-Farwell, the product of the Adams Company, Dubuque, Ia., will be found all the novel features of the Model 7A which preceded it—features which, in fact, have characterized this car ever since its first appearance on the market in 1904. Of course, the central idea of the whole mechanism is the five-cylinder horizontal revolving motor. Although rather startlingly unconventional in design, this motor has been tested by many years' service, and, moreover, its employment results in a truly remarkable simplification of the various accessories.

As may be seen from the illustrations, the five cylinders are arranged like the five points of a star. In the center is the crankshaft, vertical and stationary, the five connecting rods interlocking upon its single crank. The crankshaft being held stationary, it is evident that, when an explosion takes place in one of the cylinders, the cylinders and crankcase will be forced to revolve. A bevel gear keyed to the lower side of the crankcase transmits the power to the change-gear, which is immediately beneath the motor. The first advantage of this unusual arrangement is the elimination of all reciprocating parts. The pistons merely swing around in a circle about the crank, eccentric to the circle described by the cylinder heads. The motor forms its own flywheel, the revolving parts amounting to about 90 per cent. of the total weight. Again, the revolving cylinders act as a centrifugal blower, and cool themselves automatically by the current of air they set up.

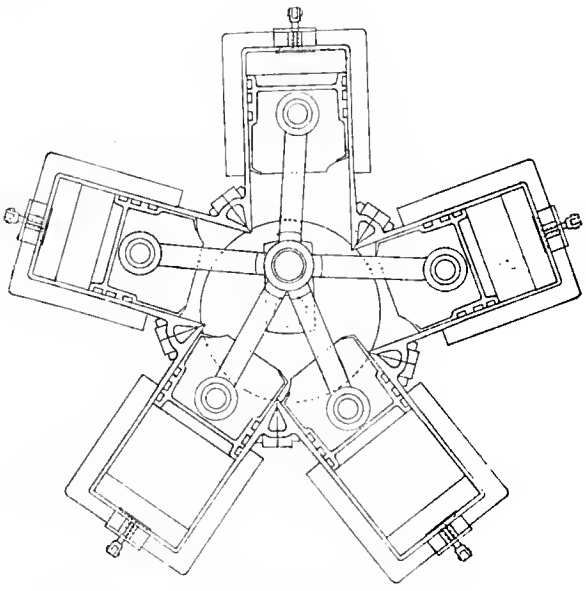
The valves are located in the cylinder heads, actuated by the now familiar walking beam with a single push rod. The push rods from all five cylinders, however, work on a single cam, concentric with the crankshaft, but caused to revolve at a slightly lower speed. The cam is made in two parts, which are movable with respect to each other, thus changing the profile. By this means the inlet valve may be held open during part or all of the compression stroke, giving a range of compression between maximum, 90 pounds, and atmospheric pressure only. The speed of the motor is controlled in this way instead of by throttling. The larger part of the exhaust is discharged through auxiliary ports at the bottom of the piston stroke. As there is never a vacuum in the cylinders, owing to the absence of a throttle, there is no need for any kind of check valves on these ports. No muffler whatever is used, as the wide distribution of the exhaust and the constant current of air rushing past the ports effectually break up the sound. Owing to the action of centrifugal force tending to hold the valves closed, the springs may be made very light.



Plan View of Adams-Farwell Chassis.

The carburetor is stationary, on top of the motor, and consists simply of a spray nozzle, an air valve, and a pump which maintains the gasoline level without a float or air pressure. The inlet pipes are cast integral with the cylinders, and connect with the manifold which surrounds the upper end of the crankshaft; all are of course exactly the same length, so that an even distribution of the mixture is assured. One feature of the carbureter is that it may be taken apart and cleaned without disturbing the needle valve adjustment. With the variable compression system of control, there is never a vacuum in the intake pipes; rather, centrifugal force comes in again and puts a slight pressure on the gas. For the same reason, the motor can be run on a much thinner mixture than usual, as the richest and heaviest gas tends to collect in the cylinder head nearest the spark plug.

Considerable simplification is apparent in the ignition system, principally through the arrangement of the cylinders to act as their own secondary distributor. Each spark plug is connected by a wire to a fiber insulator near the base of the cylinder, and a screw in this insulator is adjusted to make contact with a stationary strip of



Outline Drawing of Adams-Farwell Five-cylinder Motor.

brass to which the secondary wire from the single spark coil is attached. Thus each cylinder in turn picks up the spark as it passes under the brass strip. A timer, a single coil, batteries, and four short wires complete the equipment. Ther a single contact point, any wear affects all cylinder they cannot get out of time.

The oiler is contained in the left leg of the V-shape casting which extends over the engine and has its ap end of the crankshaft. It is driven by a worm gear springs or check valves.

The only noteworthy change from former models the change-gear. This was formerly of the four- driving indirect on all; but as the lowest gear was it was changed to a three-speed type, driving direct The gears are controlled selectively by a lever wor H-shaped quadrant. The clutch is a double cone, bro iron with cork inserts, running in oil; it is enclosed i compartment of the change-gear case. As stated change-gear is immediately beneath the motor, the ing a single unit, which is supported on a three-point Drive is by a single short chain to the rear axle. T 15 inches clearance under the middle of the car.

The five cylinders of the engine are 5 1-2 inche inches stroke, rated very modestly at 50 horsepower. Nine is fitted with two types of bodies, a seven-passe car and a four-passenger roadster; the chassis is t ccpt as to wheel-base, which is 128 inches for the 120 for the latter. Tires are 35 x 4 1-2 both fro There is an unusual amount of storage room on l all the space under the hood and the front seat bei for this purpose. Another convenience which has fo distinguished the Adams-Farwell is the self-starte device worked from the driver's seat.

MOTOR TRUCK DEMONSTRATES ITS ECONOMY

SYRACUSE, N. Y., Aug. 29.—An automobile truck in road construction work near here has furnished some remarkable figures illustrating the great economy of gasoline power over horse power. The truck is a three-ton Chase, made by the Chase Motor Truck Company, of this city, and is fitted with a special dumping body of 3 3-4 yards' capacity. Its work is hauling crushed stone from the crusher located near Skaneateles to a point three miles distant, where a road is in process of construction. It makes eight round trips every day, carrying a total of 30 yards of stone—about 40 tons. On this same work, teams are used at a cost of $5 per day per team. The teams haul 1 1-2 yards at a load and make three trips a day, a total of 4 1-2 yards a day. The truck is consequently doing the work of 6 2-3 teams, and must be worth $33.35 to the contractor.

In its daily operation the truck consumes 12 gallons of gasoline and 2 quarts of oil, costing $1.64, and the driver receives $2.50, making a total operating expense of $4.14 a day. The depreciation on $3,500, the cost of the truck, at amounts to $2.91 a day; interest on investment, $ insurance, $0.20; maintenance and repairs, $1.00. daily expense is therefore $9.05 a day, and the con $33.35 less $9.05, or $24.30 a day.

The Chase truck used on this work is two years the record is not that of a brand new machine, bu average figure of one that has seen hard service in of work. Its work on this job is attracting consid tion in the state engineer's office, as it promises large reduction in the important item of haulage e:

In making the trip from the crusher to the roa necessary to climb one hill a third of a mile long, mum grade of 12 per cent. On this grade the hors quently double up, using four horses to draw the l stone. The truck climbs this hill with its full loa the intermediate gear, using low gear only in the n

Distributing Crushed Stone Along the Road.

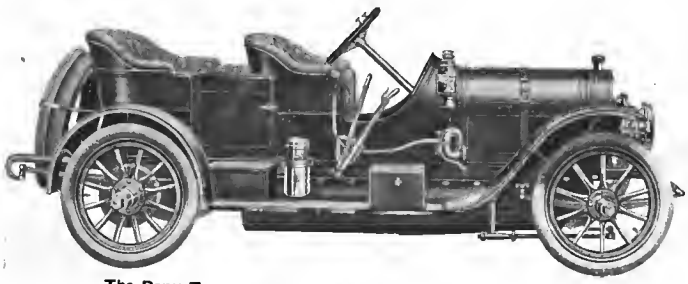
Chase Truck, Equipped with Special Dumping

THREE 1909 MODELS OF THE POPE-HARTFORD

THE Pope-Hartford line for 1909 will consist of three types, built on practically the same chassis: a touring car, a pony tonneau and a roadster. The Pope Manufacturing Company is now well able to face the coming season with perfect confidence. The new models continue the general features of former Pope-Hartford designs; the changes are mostly external. The straight-line body has been adopted, and the hood and radiator slightly modified to correspond, though not so as to impair their distinctiveness. All three models will list at $2,750.

The 30-horsepower motor retains its paired cylinders and overhead valves, but its external appearance has been considerably changed by moving the commutator, magneto and carbureter to the other side and rearranging the manifolds and water piping, with a considerable improvement in accessibility. The housing of the two-to-one gears is now cast integral with the crankcase, and a system of oil pockets and grooves has been provided to secure the lubrication of the gears from the splash in the crankcase. This, together with a new arrangement and a new method of cutting the gears, insures smooth and quiet running. The crankshaft has been increased in size, and its bearings have also been enlarged and are now of a special white brass, instead of phosphor bronze as before. The motor is mounted on a subframe so arranged as to permit the withdrawal of the camshaft and all gears without removing it.

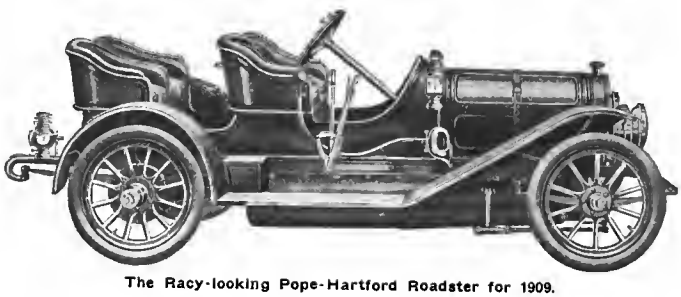
A new design of carbureter has been adopted, containing all the valuable features of that formerly used, with important changes which will insure easier starting and make flooding practically impossible. Ignition is by storage batteries and coils, but a double system with Eisemann magneto and Carpentier coil can be supplied at an extra charge. A mechanical oiler located under the hood, with a sight-glass on the dash, feeds oil to the cylinders; the main bearings are lubricated by splash from the crankcase, suitable pockets and grooves being provided for this purpose in the walls of the crank case.



The Pony Tonneau, the Latest Wrinkle in Body Design.

The transmission system follows standard and conventional lines. The clutch, of the cone type, has been increased 1 1-4 inches in diameter over last year's design, and is covered with a material specially composed for this purpose. The clutch bearing has been considerably lengthened to insure accurate centering of the cone in the flywheel. Between the clutch and the gear-set is a squared sliding sleeve, which compensates for any inaccuracies in alignment, and is adjustable to allow for any possible wear. The change-gear gives three speeds forward, operating on the selective principle. All gears are of chrome-nickel steel and the engaging ends of the teeth are beveled by a new process to insure quick and easy meshing, without noise. All the gear-changing mechanism, with the exception of the hand lever, is enclosed in the gear-case, which is supported on the frame at three points. Drive to the rear axle is through a shaft with two universal joints; a torsion rod of new design, with buffer springs, is provided to relieve it of strains due to rough roads.

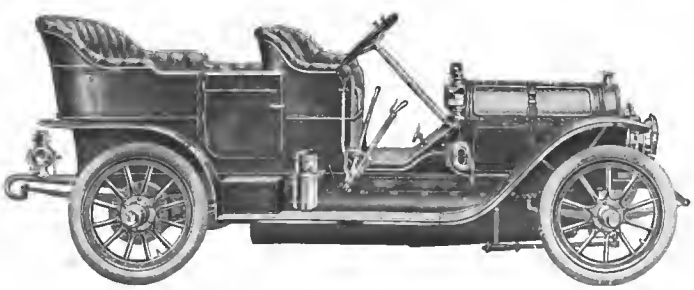
A rear axle of the floating type is used, with Timken roller bearings throughout. A screw adjustment on the bearings of the bevel pinion shaft makes it possible to take up all wear. The bevel pinion has 14 teeth and meshes with a 46-tooth gear. The two sets of brakes are arranged one on a drum just behind the gear-set and the other on the rear hubs. The latter are of the internal toggle type, fully enclosed and adjustable for wear. The front axle is a solid I-beam forging. The distinctive Pope-Hartford frame, of wood armored with steel plates, has been retained, and an additional cross-member provided to support the front end of the torsion lever. The rear springs have been lengthened from 52 to 56 inches and are now swiveled on the rear axle to avoid all strains when putting on the brakes or starting under load. The wheelbase is 113 inches and the tires 34x4 both front and rear.



The Racy-looking Pope-Hartford Roadster for 1909.

The body is much larger and roomier than last year's, and is of the latest straight-line design. The old hooded dash has been abolished and a straight one, of mahogany, substituted, in order to carry out the lines of the body. The sides of the hood are straight, instead of having a double curve, as formerly, and are hinged in three places; but the distinctive shape, which has for several years marked the Pope-Hartford, has not been perceptibly altered.

The chassis of the roadster and pony tonneau models will be the same as that of the touring car with the exception that the motor will be set further back on the frame, necessitating a slight rearrangement of other parts, and the steering column will be given a greater rake. A detachable seat for the chauffeur, on the running board, can be provided on the roadster. The body of the pony tonneau is very short, although affording ample leg-room for four people, and is correspondingly light. The rear seat is rather forward of the axle, which should make it very easy riding, and also leaves considerable room for spare tires and haggage.



1909 Pope-Hartford with Full Tonneau Body.

Palmer-Singer 1909 Skimabout

IF evidences of the renewed wave of prosperity that is already generally felt by the automobile trade, and that bids fair to surpass anything ever known in the history of the industry where the selling during 1909 is concerned, were needed to bolster up the faith of the doubting ones, they could be found in the manufacturers' plans for the coming season. For instance, the Palmer & Singer Manufacturing Company is planning to turn out about 1,000 chassis for the 1909 season, and while this would not be sufficient to place any undue burden on their splendidly equipped plant, it is a more difficult task when it is considered that this number will consist of no less than five different and distinct models. This is the same quintette with which this firm opened the 1908 season, but of the five, two have proved so popular that the original quota of cars had to be multiplied by five in order to keep pace with the demand, and the sales department of the company was so occupied in handling these models that, to quote Sales Manager Botto, "the others were left to sell themselves."

As Seen From the Front.

These two were the Palmer-Singer "Six-sixty," a six-cylinder car of 60 horsepower, and the P. & S. "Skimabout," a special runabout type of car, with a 30-horsepower, four-cylinder motor, and as a result of the great amount of popularity they have been enjoying they are naturally the first of the new line to make their appearance for 1909. The orders for the new series of these two models are already said to exceed the number of cars of this type which were manufactured during the 1908 season. The present factory plans comprehend the construction of series of 250 cars of each of these models, and it is expected that 125 of each of the other three models will be turned out during the course of the coming season, though, judging from the present demand for the two favorites, developments later in the season may make an increase in the figures, where they are concerned, a necessity.

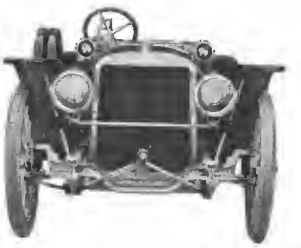
As is evident from the accompanying photographs taken at the metropolitan plant of the company, these two models are already beginning to come through in numbers, the picture showing the "Six-sixty" chassis in the course of assembling. In view of the success with which this model met immediately upon being placed on the market, and the strength of the demand now in evidence for it, there is apparently to be no let-up in the call for cars of the six-cylinder type during the coming season. They have had an opportunity to prove their merits in greater numbers than ever before during the past season, and the manner in which they have done so is quite evident from the demand for sixes for fall delivery.

The only noteworthy change in the "Skimabout" for 1909 is in the shape of the hood and the position of the radiator. Last year, it will be remembered, this speedy little car had a sloping hood somewhat resembling that of the Renault, while the radiator was under the footboards, just to the rear of the flywheel. While satisfactory, this arrangement was found to possess no particular advantage over the conventional one. So the 1909 "Skimabout," as shown in the photographs, has a neatly designed vertical tube radiator mounted in front of the engine, with a folding hood.

Assembly Room of the Palmer & Singer Mfg. Co.'s Factory.

CONCERNING THE SEVEN 1909 AMERICANS

BUILDING seven models in touring car and roadster lines, all fitted with a 50-horsepower motor, but differing in body and other minor details, is the program of the American Motor Car Company, Indianapolis, Ind., for the approaching season. This program shows a unifying of effort, as compared with the present season, in which two styles of motor have been used, one with a 40-horsepower rating and the other with a 50. The characteristic American roadster with its underslung frame is continued with certain improvements which are looked upon to greatly increase its prestige, and the different models of touring cars bear striking resemblance to this year and carry their quota of refinements, as well as those advantages accruing from the use of high-grade steels.



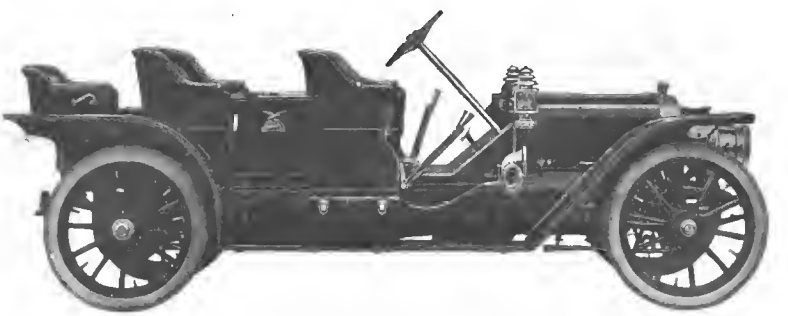
Front View 50-h.p. Roadster.

It is in the roadster, however, that some of the important changes appear. Foremost in this category is the employment of 40-inch wheels, in place of the 36-inch size heretofore used. Adding 4 inches to the diameter of the wheels, in conjunction with raising the wheelbase from 112 to 122 inches, is looked upon vastly to increase [redacted]es of this car, as well as augmenting its speed qualities, it having in tests shown 75 miles per hour with full equipment and passengers. Using the 40-inch wheels has given it a clearance of 12 1-2 inches beneath the horizontal mud-apron, which extends from the radiator to the rear of the body. This car has been christened "the American traveler."

Fifty-horsepower Seven-passenger Touring Car—Mile-a-Minute Guarantee.

American tourist cars are built in five- and seven-passenger styles, the five-passenger type carrying a single rumble seat, which, in reality, brings it into the six-passenger class. The tourist cars carry quite a few different constructions when compared with the roadsters: the roadster employs a sub-frame, to which is attached the motor, transmission and steering gear; the tourist frame construction supports the motor and gearbox direct on the side member of the frame and has these members raised 2 1-2 inches in front of the rear axle to increase the range of the rear spring action. Semi-elliptic springs are employed regularly on the roadster type, whereas on the tourists semi-elliptics are used in front and a platform suspension in the rear. The roadster carries its mechanical lubricator on the dash; the tourist has a similar oiler carried beneath the front footboards. Added to these noticeable changes are differences in radiator design, difference in steering column inclination, different location of control levers and parts, and a pressure gasoline feed system from a tank under the dash is used in the tourist types. An interesting feature of the pressure feed in the roadster is that the gasoline from the 22-gallon tank carried on the rear of the chassis is forced by exhaust pressure to a 1-gallon tank located higher than the carbureter and in which tank is a regulating float, which controls the entrance of gasoline from the main tank. From this auxiliary tank the fuel feed is by gravity to the carbureter. The object of this extra tank is that the carbureter is relieved directly from feed by the exhaust pressure. It is claimed that, where exhaust pressure feeds the gasoline direct to the carbureter, when the first sinks, opening the needle valve, and allowing extra gasoline to enter the float chamber, this gasoline is injected in a stream, which the weight of the float is incapable of immediately counteracting at the correct moment it should—with the result that the float chamber is fuller than it should be and there is danger of an overflow into the carbureter at the spring nozzle. With gravity feed from a small tank, the pressure on the carbureter is not so great, and consequently the danger of interfering with the nicety of float control is diminished.

The motor employed in all seven models is a conventional design employing four cylinders cast in pairs, each of the twin gray iron castings having an integral valve compartment on the right side in the bottom of which are contained, side by side, the nickeled steel intake and exhaust valves. These cylinder castings are supported on a two-part crankcase, the upper part being the supporting member for the crankshaft as well as taking the support of the motor on the frame, thereby limiting the functions of the lower half to that of an oil reservoir. Care is bestowed on the machining of the cylinders, each cylinder casting, after the first rough boring, being annealed to remove stresses which may exist in the casting, after which it is left to age before taking the final grinding. Each of the four pistons comes in for similar treatment, and, to retain the motor compression to the highest degree, a special grade of metal is employed for the piston rings, which is claimed not to lose its elasticity when subjected to heat. Considerable stress is placed upon the offsetting of the crankshaft. For the benefit of the amateur motorist a word of explanation may be used. In the



Fifty-horsepower Touring Car, with Five-passenger Body Equipment.

American Rear Axle—Two Sets of Expanding Brakes.

regular motor, the crankshaft is directly beneath the center of the cylinder board, but in the offset shaft it is placed nearer the right side, the reason of this being that on the explosion stroke the connecting rod has less angularity than if the crankshaft were located in the center. This diminishing of the connecting rod angularity reduces the pressure on the side of the cylinder during the explosion stroke, which should result in an increase in power, a diminution of the wear on the piston rings and a reduction of the vibration in the motor. With the offset crankshaft, while the angularity of the connecting rod on the explosion and suction strokes is lessened, it is true it is increased on the compression and exhaust strokes, in both of which, however, the work done is small in comparison with that of the explosion stroke. Connecting rods are special alloyed steel forgings, built in "H" sections, carrying hardened bronze bushings in their upper ends, where they attach to the wrist-pins, and have at the lower ends the usual marine construction with a cap secured by double-nutted bolts and split pins. Lastly, and most important of the moving parts of the motor, comes the forged crankshaft made from a solid billet of steel, after which it is heat-treated and machined to balance. Freedom from vibration is aimed at by finishing the bearings to accuracy with a grinding process. In attaching the different gears to the camshaft, as well as to the other motor shafts, the use of a flange on the shaft to which the gear bolts is resorted to.

In manufacturing the cylinder castings, the large aluminum plate acting as a lid or cover to the water jacket in each twin casting is made use of, the claimed advantages of such construction being the certainty of removing all core sand in the foundry, as well as the increased facilities offered for cleaning.

Viewed exteriorly, the motor is a well-balanced unit, in spite of its design calling for the location of both sets of valves on the right side. Grouped on the right are the valves, the carbureter, the timer for one set of ignition and the intake and exhaust manifolds; on the other side, a casual inspection reveals the Bosch high-tension magneto and the centrifugal water pump, the pulley on the end of the pump and magneto shaft for driving the fan and, in the roadster motor, to these must be added the gravity feed gasoline tank carried opposite the space between the cylinder cas order to avoid puncturing the half-time gear ho fan pulley on the pump shaft is located in the rear of ing.

Intake and exhaust valves, made interchangeable, an from the same camshaft, have the push-rods and rol ened, and the push-rod guides are secured in the cra a four-arm yoke with center bolt; one yoke securing for the intake and exhaust valves for each cylinder. ends of the valve push-rods are threaded to take an and lock-nut for valve timing. The intake manifold piece casting made with easy curves, and the exhaus (a large-sized malleable iron casting) is of the horiz piece type and is ribbed to increase strength. Locati take manifold below and closer to the cylinders than th manifold has the advantage of tending to prevent the tion of the mixture en route from the carbureter to th

Ignition is by two independent sets, the main one high-tension magneto which incorporates within itself for high-tensioning the current, the make-and-break the distributing means. With a system of this na carried on the dash or beneath the car seats are done and distributers or commutators on the engine are Wiring is reduced to a minimum. on the top of a stationary aluminum housing on the of the motor between the front and rear cylinder cas vertical shaft carrying the timer takes its drive fro shaft through helical gears, and, in advancing or re spark, the commutator part carrying the wires rema ary, the advance or retard being accomplished by ch relation between the gear on the camshaft and that o shaft. The wiring is run through fiber tubing and th on the spark plugs are so designed as to be removed engine, when it is in operation, without danger o

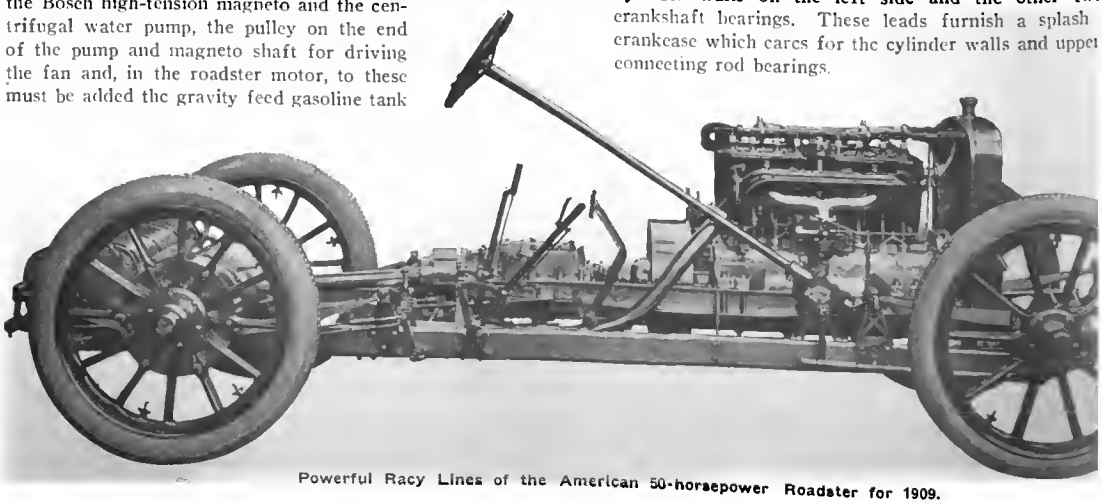
The lubrication of each model calls for a six-spe ical lubricator, four of the leads of which connec cylinder walls on the left side and the other tw crankshaft bearings. These leads furnish a splash crankcase which cares for the cylinder walls and upper connecting rod bearings.



Powerful Racy Lines of the American 50-horsepower Roadster for 1909.

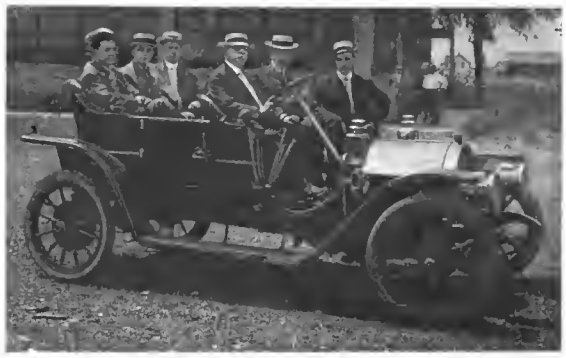
In the cooling system the centrifugal pump located centrally on the left has a double intake to increase its capacity, and in keeping with this is the employment of large diameter pipes. The circulation is from the pump to the jackets immediately beneath the exhaust valve, this being the hottest part of the engine. The exit is from the cylinder heads, the pipe therefrom branching in "T" form to the upper sides of the radiator. The radiators employed in both tourist and roadster types are of the vertical copper tube variety, with 5 1-2-gallon capacity in each. In both radiators the vertical copper tubes are narrow and the radiating quality is increased by the addition of a piece of sheet copper from which there are punched small corrugated fins, which corrugations attach to the tubes by immersion in a solder bath. With this construction all seams in the copper tubes are on the front and back surfaces, permitting of repairing a leak by the use of the soldering iron. In addition there is a 16-inch fan supported on an arm from the front cylinder and driven by a 1-inch flat belt.

First in the transmission system is the leather-faced cone clutch. The thrust is self-contained and is taken on a ball thrust-bearing. In the disengagement of the clutch, the strength of the spring is overcome by giving the clutch pedal leverage a nine-to-one leverage. Between this clutch and the selective gear is a universal coupling in which the square ends of the coupled shaft engage with square driving heads, which are made in halves and divided longitudinally, so that they may be uncoupled by removing the bolts which hold the halves together. This coupling allows of removing either the clutch or the transmission without interfering with the other.

The gear-set, a standard construction, gives four forward speeds, direct on the high, and has a reverse in which the gear revolves only when in use. Chrome nickel steel is employed in all gears, and the shafts are of special alloy steel and are carried on ball-bearings. The shaft which carries the sliding gears has four splines milled on it, a construction which eliminates keys and other parts not integral with the shaft.

Drive from the change-gear is through a propeller shaft with universal to a floating rear axle on the ends of which are claw clutches for engagement with the wheel hubs. A tubular torsion rod completely encases the propeller shaft, and at the front end of it is a universal joint support carried on the cross member of the frame, which acts as the support for the rear end of the gear case.

In a close scrutiny of the running gears employed on the roadster and tourist cars a standard construction based on conventional lines appear. The touring car frames are built up of two side members and three cross-pieces of alloy steel; the side channel members have a maximum depth of 5 inches, a 1¼-inch web, and 3-16-inch stock. The crankcase acts as a cross member at the front. The roadster frame, of the same stock, has the side members narrowed at the dash to increase the turning angle of the car, and, as already mentioned, employs a superframe. The springs employed on the touring car are 42 inches in front, and the three-part platform suspension of the rear has the side members 48 inches long and the transverse member 39. The side members are offset on the axle so as to make the front end equal in length to the rear end plus half the length of the cross frame, which is supposed to give the same spring action as from a semi-elliptic 67½ inches long. Compression grease cups are provided at the head of each spring bolt.



Officers of the Chalmers-Detroit Motor Company.

E. R. Thomas is at the wheel, with Mr. Chalmers sitting beside him. H. E. Coffin, vice-president and designer, is standing up. In the back seat is J. J. Brady, second vice-president and factory manager, and next to him is F. O. Benzer, secretary; while next to him is Roy D. Chapin, treasurer and general manager.

A NEW RENAULT FOR AMERICAN ROADS.

In order to meet the demand for a car designed to meet the unusually strenuous conditions presented by American roads, Manager Paul Lecroix, of the Renault Frères selling branch, is now importing a new model especially designed for this purpose. The motor is a four-cylinder, 20-30 horsepower type, and is characterized by the usual features that have become familiar on the Renault motors during the last five or six years. But the chassis itself is lighter, shorter and narrower than the standard Renault chassis of the same kind designed for town use. The springs have been reinforced, the Renault liquid shock absorbers fitted, sturdier axles employed, and in every way the car has been fitted to travel over rough roads at a good speed.

The matter of clearance has come in for special attention, full 10 inches being allowed, the wheelbase being 120 inches. While the water-cooling system is of the same type as that which usually distinguishes the Renault, that is, with the copper tube radiator back of the motor and theremo-syphon circulation, the radiator itself, in this case, has been considerably enlarged, and the bonnet has been made much longer. The control levers are much shorter than in the regular type. As a runabout this car is capable of 60 miles an hour, and has been designed with a capacity for high speed on rough roads. The complete chassis tips the scales at 2,000 pounds, and when equipped with a runabout type of body lists at $6,000.

New 20-30-h.p. Renault—Manager Paul Lacroix at Wheel, with Madam Lacroix Beside Him.

THE IMPORTANCE OF ROAD CONGRESSES.

No more significant indication of the awakening public interest in good roads could be cited than the various congresses of road-makers which are being held in all parts of the country. Last week the American Association of Park Superintendents met at Minneapolis; during the latter part of this month the New Jersey grange and automobile clubs will hold a joint convention at Atlantic City; and then, in October, will come the International Road Congress at Paris.

These congresses mean that road building and maintenance must now be undertaken scientifically. Hitherto, in most parts of the United States we have been working our roads under about the same system as was in use in France at the time of the French Revolution. Every petty road official was left entirely to his own judgment as to how the work should be done. One preferred narrow roads, another wide roads; one said roads should be flat, another said they should be crowned; but nearly all agreed that the best repair materials were brickbats, sod and brush. Some States had laws requiring all able-bodied men to work a certain number of days a year on the public roads, and others allowed property taxes to be worked out in the same way. Nobody ever expected a day's work from a man who was working out his tax, and the occasion was usually looked upon as a huge joke. No system ever inven more ingeniously planned to accomplish nothing

Happily, most of this has been changed. All t thickly settled States, at least, have passed some State aid legislation, and have responsible off charge. But it cannot be expected that the mer priation of so many thousand dollars will insure quate improvement in the roads, or that the of the office of "State road supervisor" or " sioner" at so many dollars a year will instant forth a man competent to fill the position. The of roads—real roads, not strips of unoccupiec is a science, and cannot be learned in a day.

Moreover, it is a science which is just nov going important changes. The increasing use mobiles running at high speeds has introduced a which as yet remains unsolved. Just what da any, a rapidly moving automobile does to a r road does not seem to have been definitely set there can be no doubt that many of the prese damage the automobiles, or, at least, seriously from the pleasure of riding in them. Of cour calamity howlers will say this only proves that t of automobiles should be more rigorously r But this country cannot afford to stand in the progress, even for the sake of preserving a mu and more expensive system of roads than we possess. Most road builders see the matter in tl light, and admit that if our roads and our au do not agree, it is the roads which must be cl

VANDERBILT RACE AN INDUSTRY'S

Whether one interested in racing, but not in ing war," accepts as logical the attitude of the in its refusal to adopt "international" condi the 1908 Vanderbilt Cup race close to New Y and whether one comprehends how the A. C. energetic part of it, became convinced that it v fied in running at Savannah what is practically in this country for the European makers, that person would still wonder at the continuance o tion which threatens a chaos in competition ar sequent loss of interest by the general public. bile racing of the high-speed sort is not desti long life. The A. C. A. may have the credit ening it considerably, and the price which it will total not a few thousands of dollars. C the racing element of the club will stubbornly o compromise as long as it can have its bills O occupy the center of the stage. But the reckoi come sooner or later.

Just now it does look as though the America would see how much it is to their advantage t the support of the classic Vanderbilt, and h selves by helping it, and leave the foreigners t themselves in the Southland with a minor editi French Grand Prix. The wisdom of the Ki pany, the Mora, Acme, and Chadwick should ample for a deluge of American entries for w "American event," will be of far greater imp automobile-buying public than a race designat ternational." A Vanderbilt race failure will l tive injury to the industry. It should not possible by any controversy of the moment.

KANSAS CITY CLUB LOYAL TO A. A. A.

President William H. Hotchkiss, of the American Automobile Association, Tuesday received the following telegram from the Kansas City Automobile Club, which is self-explanatory:

Cannot understand why rumor is so persistently circulated that the Automobile Club of Kansas City has withdrawn from the American Automobile Association. We wish to express to you most emphatically our allegiance to the American Automobile Association and to authorize you to deny any statement to the contrary. (Signed) W. W. COWEN, President,
Automobile Club of Kansas City.

BUFFALO CLUB LEADS IN ACTIVE MEMBERS.

BUFFALO, Sept. 1.—The Automobile Club of Buffalo, of which Frank B. Hower is the president and D. H. Lewis is the secretary, now has 1,394 active members, which gives it the largest active membership of any club in the entire country. The Automobile Club of America only has 1,307 active members, though it has an associate list of 335.

President Hower anticipates that the Buffalo club will have 2,000 members before the end of the year. In view of the fact that the best results for automobiling generally are the prime consideration of the club, it believes that members and a moderate membership fee constitute the best means of securing that which is desired.

LOUIS KISSEL VICTIM OF ASSASSIN'S BULLET.

MILWAUKEE, Wis., Aug. 31.—Louis Kissel, president of the Kissel Motor Car Company, of Hartford, Wis., is dead, the result of an assassin's bullet. Mr. Kissel was shot in his office on August 20 by John Gerbier, a Polish employee, who had fancied grievances and gave Mr. Kissel no opportunity to hear them. Mr. Kissel lingered between life and death in the Milwaukee Hospital here until Friday, when life ebbed away. Septic peritonitis was the immediate cause of death. Mr. Kissel was born in Germany on August 14, 1838. He came to Washington county, Wis., at the age of 19. Thirty-five years ago, having gained a competency on his farm, he moved to Hartford, the county seat, and with his sons established the city's first important industry, the Hartford Plow Works. He founded the Hartford Lumber Company, the First National Bank of Hartford, the Northrup-Tenteal Fur Company, the Hartford Electric Company, the L. Kissel & Sons Co., manufacturers of implements and vehicles, and lastly, the Kissel Motor Car Company, which has come to be the most important and largest industry in east central Wisconsin.

MITCHELLITES HAVE FAMILY REUNION.

RACINE, Wis., Aug. 31.—Concluding the most novel three-day conclave of agents that ever assembled at a motor factory in annual business-pleasure meeting on last Saturday evening, 125 men, who dispose of the Racine-made cars, left their homes, which are in 34 States and far-off Alaska, Porto Rico, and the City of Mexico, bound in honor to dispose of more than $4,000,000 worth of 1909 Mitchell cars—the estimated output of the big works.

President William Mitchell Lewis, of the Mitchell Motor Car Company, Sales Manager James W. Gilson, Secretary G. V. Rogers, Designer John Bate, and James Cram, who acted as hosts for the annual "family gathering," provided a three-day melange for the men who sell cars and address the company officials familiarly as "Bill," "Jim," "Jack," etc., that began Thursday, August 27, with an inspection of the enlarged plant and soon changed to a series of luncheons and dinners at the Racine Golf Club, with a special performance at a local theater monopolized for the evening by the Mitchell company for its guests. Practically all of the allotments for the 1909 output were made in a short session in Mr. Gilson's office on the morning of the first day of the convention.

TIRE PRICES GENERALLY LOWER.

CHICAGO, Sept. 1.—As anticipated, to-day saw a general revision of list prices on motor car tires by the leading makers. Some of them have not as yet made their formal announcements, but those that haven't declare they will have their statements ready inside of a week. However, the Fisk, Diamond, and Goodrich came out with their announcements to-day, while the G & J, Goodyear, Firestone, and Morgan & Wright have their lists about ready to give out.

Without going into details, it is evident that there has been a general reduction all along the line, which will average up at about 15 per cent. The users of big tires will profit more by the reduction than any one else, in some cases the reduction on tires of 36-inch sizes amounting to 20 per cent.

The Fisk company held its session here in Chicago last week. Following this meeting, B. H. Pratt, of the company, had the following to say:

"This revision of prices means that the tire business is down to a hardpan basis. It means that the tire manufacturers will have to do twice as much business to make the same profit as they did in the year just ending. But we are not complaining, for the outlook justifies us in revising the lists. The new list means that the percentage between the tire companies and the dealers and makers will be cut down and that the users of tires will be the ones to profit most. It also means that the price-cutters will be frozen out and that the trade will be thrown into legitimate channels, that is, the dealers and garage people will get the business. The reductions range from 14 to 20 per cent., as, for instance, in the bolted tires made by us there is a 20 per cent. reduction in the 36 by 5-inch size."

"The G & J prices are not ready to announce yet," declared F. S. Cropley, of that concern's Chicago branch. "We are going to have a new list, though, and as is the case with the others, it will average about 15 per cent. reduction. The consumer is going to be the one to profit most by the changes, and the dealers' profit is going to be cut about 10 per cent. by all the rubber concerns."

REDUCTION IN TIRE PRICES ANNOUNCED.

AKRON, O., Aug. 29.—The Diamond Rubber Company announces a reduction in the price of their tires averaging 15 per cent., to go into effect September 1. Perhaps the most notable feature of the change is the placing of the quick detachable type of tires on the same price basis as the regular clinchers for one-piece rims. This is especially important for the reason that the quick-acting rims are being used more and more every year. However, the prices for 1909 are materially lower for every type of tire and for tubes as well as casings.

"The standardization of tires has made rapid progress," said Theo. Weigele, of the Diamond company, recently, "and in time to come will go still further. Quality and price will, of course, both be factors in the public's selection. We are able to join with the automobile manufacturers in the reduction of price by reason of our increased output and improved manufacturing methods. And in more ways than simply lower prices will the automobile owner get more for his money. The improvements we have made considerably increase the mileage tires will give and reduce tire repair bills at the same time. We plan to keep our plant in operation to its fullest capacity right through the fall and winter, and our output of 1909 goods, dating from this time, will be about 100 per cent. larger than last year."

BRUSH CLIMBS TO TOP OF PIKE'S PEAK

DETROIT, Aug. 31.—Trinkle, the driver of the Brush efficiency car No. 3, wires from the summit of Pike's Peak: "Brush climbs all way on its own power."

"Brush No. 3" is one of the five Brush runabouts which were recently dispatched from this city to various parts of the country on demonstrations of their efficiency.

LIVE DOINGS OF THE AUTOMOBILE CLUBS

JERSEY CLUB DETECTS FRAUDULENT TRAP.

NEWARK, N. J., Aug. 31.—Following a number of complaints about the method of operation of Justice Housell's police trap at Highland Park, just outside of New Brunswick, the Board of Directors of the New Jersey Automobile and Motor Club instructed J. H. Wood, a member of the Legal Committee, to inspect it and obtain evidence to be brought before the State Motor Commissioner. Mr. Wood located the trap and watched its operation for some time. The timing was done by two boys, over an alleged quarter-mile stretch. The signaler at the beginning of the course stood over a hundred feet inside of the mark and signaled most cars when they came opposite him. When a car was going slowly he did not signal until it had gone two hundred feet past him, thus depriving the car of about one-fifth of the course. If the car covered this distance in less than 35 seconds the stop-watch man signaled to the constable, a quarter of a mile further down the road, who in turn arrested the driver. Justice Housell at first said he had had the course surveyed, but could not produce a surveyor's certificate. Later he admitted that he had used a tape measure. The constable and the two boys received fifty cents apiece for each arrest. The matter is now in the hands of the club's attorney. As a bald attempt at fraudulent extortion New Jersey automobilists consider this, the latest effort to hold up law-abiding drivers, to be about the limit. It is hoped the matter will be pushed to the limit and the offending "justice" severely punished.

NEW YORK CLUB NOW PLANS SCENIC TOUR.

NEW YORK, Sept. 2.—The "Ideal Tour" of New England, promoted in the early Summer by the Automobile Club of America, proved so picturesque and pleasurable to the coterie of participants that the club plans an Autumn run. The route selected by its bureau of tours is deemed rich enough in scenery to justify naming the proposed junket-a-motor "the scenic tour." It will be an eleven-day run, starting on September 28 and ending on October 8. The itinerary mapped out follows:

Sept. 28	New York to Mt. Pocono, Pa., via Del. Water Gap	100
Sept. 29	Mt. Pocono to Binghamton, via Wilkes-Barre	91
Sept. 30	Binghamton to Watkins	72
Oct. 1	Remain at Watkins	0
Oct. 2	Watkins to Richfield Springs	124
Oct. 3	Richfield Springs to Lake George	105½
Oct. 4	Lake George to Bluff Point (Plattsburg)	105
Oct. 5	Remain at Hotel Champlain	0
Oct. 6	Bluff Point to Manchester, Vt., via Burlington	108
Oct. 7	Manchester, Vt., to Waterbury, Conn	138
Oct. 8	Waterbury, Conn., to New York	92
	Total	935½

The route chosen crosses the Pocono and Catskill mountains, the foothills of the Adirondacks, enters the Lake George and Lake Champlain region and carries the caravan finally across the Green Mountains, whence the finish in New York will be reached by way of Waterbury, Conn. The route will be marked by green arrows with numbers referring the tourists to route cards.

MARYLAND CLUB TO AID GRAND JURY.

BALTIMORE, Md., Aug. 29.—The Grand Jury of this city has joined forces with the Automobile Club of Maryland in efforts to abolish accidents and reckless driving of automobiles. The jury has adopted resolutions favoring a scheme to compel drivers, whether owners or chauffeurs, to pass examinations and secure licenses showing that they are capable of operating automobiles in an efficient manner. The Automobile Club at its next meeting will take action upholding the resolutions of the Grand Jury. The club already has a bill nearly ready which requires drivers to pass an examination before an efficient jury before being allowed to drive a machine through the city streets and suburban highways.

MINNEAPOLIS CLUB IS A MODEL OF

MINNEAPOLIS, MINN., Aug. 31.—The Minneapolis A Club recently opened its new country clubhouse with ar reception to bondholders. The house has been open three weeks, and has been the center of automobile i the Twin Cities. The plans which have been carried c Minneapolis club have been more pretentious than at pected, and universal satisfaction is expressed at the tained by the officials in charge of the work.

The new clubhouse is located on a magnificent bl Minnesota River valley, 16 miles from Minneapolis, road. It is in the center of a stretch of country whicl many of the most popular drives about the Twin C can be reached by way of Minnetonka, or from St. P or 60-mile drives, or direct from Minneapolis in a 16-r The house has been arranged to provide ample social a Provisions have been made for house parties; a kitcher in the most modern manner, and with facilities for c 200 guests has been built; and a café service equal to in the cities has been inaugurated.

The social end of the Minneapolis Club is subordina ever, to the interests which induced its organization conspired to its growth. Directors of the club empl

New Country Club House of the Minneapolis Automol

fact that the erection of the new $20,000 clubhouse maintenance of the town and country houses, is sole purpose of reaching all interests of the automobilist, a to the strength and activity of the club. The Minnea has now a membership of 700, and this number is expected to reach the 1,000 mark this winter. With t strength, the club will greatly extend the scope of its protecting the rights of the automobilists from unjust l in pushing good roads work along scientific lines; an piling touring information, and providing signposts boards for the traveled roads of the State.

The clubhouse just completed was erected by the $15,000 worth of bonds. It has been constructed in modern manner of concrete throughout, and is a mod club building. The total length of the structure is In the center is the main section of the house, t high, and containing the main reception room, the furnished in Flemish oak, the offices, and on the se sleeping quarters and bathrooms. The whole struc model of modern comfort and simple elegance.

A porch 90 by 35 feet runs across the river fro building. It is enclosed by wire netting, and is arrang the summer as a dining room, and from this porch a be had up and down the river for almost 25 miles. furnishings of the clubhouse, designed by George H chairman of the building committee, are all represe parts of automobiles, and carry out the spirit of the

The club has ten acres, running down to the Minnesota River, and is figuring on the aequisition of eight more aeres.

The Minnesota River is a favorite stream for canoeists. Plans are now being made by the automobile club for the building of a harbor 60 feet square, at the foot of the club's grounds, and the arrangement of storage place for 100 canoes, under the broad porch of the clubhouse.

Great credit is given to the directors of the club, and the building committee, for the hard work they have done. As chairman of the building committee, George H. Daggett gave personal attention to all the details of the work. R. R. Colburn, of the firm of Kees & Colburn, the clubhouse architects, and C. F. Haglin, the contractor, were both members of the building committee. The other members were Col. Frank M. Joyce, Harry E. Pence, and E. L. Brown.

BINGHAMTON AND SCRANTON GET ACQUAINTED.

BINGHAMTON, N. Y., Aug. 29.—The Board of Governors of the Binghamton Automobile Club, at a meeting held August 19, accepted in behalf of the club the invitation of the Scranton Automobile Club to participate in a meet which the latter club will hold on the Hartford Fair Grounds September 5. They expect to have a number of fancy races, a tug-of-war, with Binghamton on one side and Scranton on the other, a ball game, a tire-changing contest, an obstacle race and an egg race. In the egg race a basket is placed at the starting point and at distances of 100, 200 and 300 feet other baskets containing eggs are placed. The contestants, consisting of a lady and a gentleman in each car, start at the signal from the starting point, the lady being armed with a teaspoon, and at either the first or last basket, as they see fit, the lady dismounts, takes up an egg in the teaspoon and carries it to the starting point, where she deposits it in the basket without touching it with her hands. The one safely depositing an egg from each basket in the basket at the starting point wins the race.

The main object of the meet is for the automobilists of this section to become better acquainted, with the ultimate object of forwarding the good roads movement.

OCTOBER DATES FOR CLEVELAND CLUB.

CLEVELAND, Sept. 2.—The dates for the Cleveland Automobile Club's reliability contest will be Oetober 7, 8, and 9, while the course will in all probability be a three days' triangular affair. Last year the cars ran in and out of the city each day, but this plan was found not to give any too much satisfaction.

A. C. A. ACQUIRES MORE REAL ESTATE.

NEW YORK, Sept. 1.—The Automobile Club of America has purchased three lots on West Fifty-fifth street in the rear of its present holding. The price paid was $150,000. An addition to its present clubhouse will be built affording more garage room and an entrance on two streets.

ANOTHER CONNECTICUT BELIEVER IN SIGNS.

WILLIMANTIC, CONN., Sept. 1.—The recently formed Automobile Club of Willimantic has outlined a vigorous sign posting campaign and will expend surplus funds in this direction rather than otherwise.

MORE SPACE FOR INDEPENDENT SHOW.

Applications for space and diagrams for the international show to be held at Grand Central Palace, New York, December 31 to January 7 next, have been mailed from the executive offices. Extra space has been secured by converting the big room heretofore used as a vitagraph theatre to exhibition purposes and by the removal of several partitions. The show committee is to meet to-day to pass upon the decoration scheme and pictorial posters.

HOMECOMING OF THE PREMIER CENTURION.

INDIANAPOLIS, IND., Sept. 1.—A great welcome home was given the Premier Century car last Friday when it reached within hailing distance of the Hoosier capital after a most successful trip through the East and over the route home via Baltimore, Hagerstown, Bedford Springs, Pittsburg, and Columbus, the Glidden Tour route of 1907. The welcome took place in the form of a chicken dinner at Greenfield, twenty-five miles east of Indianapolis, the company having as its guests about fifteen local and out-of-town autoists.

When Pilot Joseph Moore arrived at Greenfield his car had gone 10,625 miles, but to hear his engine, one would not have suspected that he had driven one-fifth that distance. Every cylinder was hitting to perfect time and the running could scarcely be heard. The condition of his engine was remarkable in the fact that not one part of its equipment has been replaced nor has it received more than ordinary care due an automobile. Moore stated positively that the only thing done to it was to fill it up with gasoline, water, and oil before starting each day.

What has proven to be one of the most interesting chapters in motordom was started on June 1. On that day the Premier Company started one of its stock cars on the run of 100 miles a day for 100 days in order to demonstrate the good qualities of

Premier Century Car in Foreground.

Joe Moore is drtvtng. All cars in picture took part in Glidden tour. Thts party welcomed Moore on his return to Indianapolts.

the motor car of to-day. The car was run the required distance every day around Indianapolis for a while and was then driven to Chicago and return. After a few more trips around the Hoosier capital it was driven to Buffalo to take part in the Glidden Tour as a press car, and incidentally it covered far more than the 100 miles a day scheduled. It went through the tour in good shape, making every control on time. Following the finish of that event it was driven to Boston, New York, Washington, Philadelphia and several other Eastern cities. It was then headed towards home. The stunt of the century is officially scheduled to end September 8, but it has not been definitely decided as yet where the last day's run will be from. Announcement of this will be made later.

KOKOMO'S FIFTEENTH AUTO ANNIVERSARY.

INDIANAPOLIS, IND., Sept. 1.—A large number of automobile enthusiasts from this city will go to Kokomo tomorrow, where the fifteenth anniversary of the founding of the automobile industry in Kokomo will be celebrated.

Just fifteen years ago Elwood Haynes built his first gasoline automobile, now on exhibition in the Smithsonian Institute. Shortly afterwards the Haynes-Apperson Automobile Co. was organized, developing later into the Haynes Automobile Co. and Apperson Brothers.

A program appropriate of the occasion has been arranged and thousands of visitors are expected in the city.

News in General

Holsman Brigade Figured Prominently In Recent Hill Climb at Algonquin, Ill.

The Substitution Evil.—All automobile owners who take an active interest in the welfare of their cars realize the importance of using a proper grade of cylinder oil. Unfortunately some dealers make a practice of selling cheap and worthless oils under the names of reputable brands, and manufacturers of high-grade cylinder oil find it practically impossible to protect their interests and those of their customers against this substitution. The G. A. Haws Company, manufacturers of Panhard oil, quote a letter from T. T. Southwick: "Now I am a manufacturer and an active competitor, but I mean to be a decent one. It is an outrage on reputable manufacturers of high-grade oils and on the consumer who pays the price of a good oil for dealers to substitute an inferior oil, and yet I know, and you know, it is widely practiced, and that, too, by a class of dealers and garages that ought to be above such petty trickery. I know of large garages that sell from four to six brands of oil, and they buy only one, and pay less than 15 cents a gallon for it." These cheap oils are practically certain to cause heavy deposits of carbon in the cylinders, and the dealer who supplies them to an automobilist trying to buy a good oil not only defrauds his customer, but also risks ruining an expensive engine.

A Farmer Who Dissents.—In the opinion of a prominent Wapping farmer, the motor car is the greatest plague that exists on the country roads for the resident that suffer in consequence. He states: "The evils are numerous, fast running, the smell of gasolene, the immense clouds of dust, the destroying of roads, the fear of danger of meeting them, and the destruction of fowls." This individual is of the opinion that people can no longer enjoy their lawns and verandas in the good old Summer time. He is apparently something of a "timer," for he has discovered cars that actually went eighty miles an hour and asks if the next Legislature will stand for this sort of thing. He furthermore contends that the roads of to-day are a failure, bad for the horses' feet, etc. He winds up with a plea for the old roads, meaning, presumably, the soft country dirt variety, where one wallows in the mud after a heavy rain. His neighbors, however, drive cars and seem pretty well satisfied with things in general.

They're After Van.—The creditors of Van's Auto Tire Company, of 792 Seventh avenue, New York, which was incorporated on Feb. 25, 1908, with a capital of $10,000, has filed a petition in bankruptcy. The creditors, who signed the petition, are Republic Rubber Company, $236; the Hartford Rubber Works Company, $652, and the Mutual Auto Accessories Company of America, $268. They allege that the company is insolvent, removed and concealed its entire property except some rubber tools and machines of small value, purchased upon credit goods largely in excess of the amounts usually bought in the regular course of business, and immediately thereafter disposed of the goods, some at less than cost, and the remainder concealed in some place unknown to creditors, and the company kept the proceeds.

Offer for Pope-Waverly Plant.—Albert L. Pope, George A. Yule, and Egbert J. Tamlyn, receivers of the Pope Motor Car Company, have issued a statement to the creditors of the Pope Manufacturing Company which controls the former concern, setting forth an offer of $200,000 for the Pope-Waverly plant made by Herbert H. Rice and Wilbur C. Johnson. The offer is cash, and a hearing will be given on the matter before the Court of Chancery at Newark, Sept. 8. Messrs. Rice and Johnson have deposited $5,000 on account of their offer, the amount to be returned to them in the event of their not acquiring the plant. In the receivers' statement it is announced that the Rice-Johnson offer is the best ever received by them. The court hearing will, of course, decide whether or not the offer can be accepted. The Pope-Toledo hearing comes up on the same day.

Sleepers for Glidden Tour to Denver.—Since the proposal was made that the Glidden tour of 1909 be run from New York to Denver, there has been no little discussion of the practicability of the route from the standpoint of our night accommodations, particularly between Chicago and the Colorado metropolis. A moving camp pitched by professional tent men was the first suggestion. Col. Charles Clifton, of the George N. Pierce Company, is inclined toward the use of special trains. "The trains," says he, "would furnish food and lodging far better than would crowded hotels and at less cost. The tourists would have new, comfortable quarters, and a trouble would be saved by atta gage cars to the train."

Sales Records Broken.—All midsummer sales of Rambler broken during the month of cording to Thomas B. Jeffery & announcement. During last m sales were three times as large August, 1907, in spite of the fa was the greatest year in the his Rambler business. This is rega indication that the attitude of t bile buying public is changing a automobile can maintain its po the year round, appealing to bu in the late summer and fall as spring and summer.

Fort Pitt Motor Mfg. Co.—There has has been no reorganization of the Fort Pitt Motor Mfg. Co., according to information received from New Kensington, Pa. It was stated in "The Automobile" last week that George Von Rottweiler was reorganizing the Fort Pitt Co., but the latest information supplied is to the effect that he is organizing a new concern, of which he will be the head.

Another Auto Line.—A wide-awake Collinsville, Conn., man has started an auto bus line to connect with the Unionville trolley. The Collinsville trade practically all comes to Hartford, but hitherto there has been no trolley connection nearer than Unionville. This gap will now be covered by the automobile. A Knox truck accommodating twenty passengers will be used.

Forging Plant Resumes.—The Springfield Drop Forging Company, whose plant has been operated for the past five years by the Page-Storms Company, is, by the expiration of the lease, again in possession of its plant, dies, machinery and fixtures, and will continue making the same line.

Aid for Zeppelin.—The Continental Caoutchouc and Gutta Percha Company of Hanover has subscribed £750 to the Zeppelin fund.

IN AND ABOUT THE AGENCIES.

Studebaker.—A new company has been formed to represent the Studebaker in Harrisburg, Pa. It will make its headquarters at the old garage of the Capital City Auto Company on Market street, and in addition to its agency business, will carry a full line of supplies and accessories. A first-class repair shop is connected with the garage.

Stoddard-Dayton.—Andrew S. Robinson, formerly connected with the Harry S. Houpt Company, agents for the Thomas car in New York City, will on September 8 take up new duties as sales manager for the Hamilton Auto Company, Philadelphia agents of the Stoddard-Dayton.

B. L. Toplitz-H. H. Holmes.—The Allenhurst garage of New York has discontinued the Midland agency. Its managers, Messrs. Toplitz and Holmes, are in the West arranging for another agency, said to be of a well known and established line of cars.

"Autogas" Tanks.—The New York branch of the Avery Portable Lighting Company, Milwaukee, Wis., makers of the "Autogas" acetylene tanks, will remove Sept. 1 to 243-5 West Fifty-seventh street, in the New Thoroughfare Building.

Schacht.—The Audubon Garage and Machine Works, 415 West One Hundred and Fiftieth street, New York City, has taken the New York agency for the Schacht high-wheel runabout, made by the Schacht Manufacturing Company, Cincinnati, O.

Reo.—Otto Owen, brother of R. M. Owen, and B. C. Buxton have organized the Reo Automobile Company and will look after the Chicago interests of that car. Their salesrooms will be at 1218 Michigan avenue.

Schacht Auto Runabout.—The Philadelphia agency for the Schacht runabout has been secured by D. Applegate & Co. and quarters have been fitted up at 326 North Broad street.

Empire Tires.—The Empire Automobile Tire Company, Trenton, N. J., announces that it has arranged for a Cleveland agency with E. T. Horsey, 1268 Euclid avenue.

Lozier.—The General Motor Car Company, Philadelphia agents for the Lozier, has moved into new quarters at 227-229 North Broad street.

PERSONAL TRADE MENTION.

Charles F. Greuter, for some time connected with the Matheson Motor Car Company as designer, is said to be seeking capital with the idea of forming a new company to build automobiles. The concern will start with a capital of $200,000, and much of the material to be used in building the cars is said to be already in sight. The factory will probably be located in Wilkes-Barre, as several sites in that town are said to be under consideration.

George H. Smith.—Prior to his leaving town to take up his new duties as Northern New Jersey representative of the Winton, George H. Smith, former manager of the White branch house in Philadelphia, was tendered a farewell dinner by "The Shock Absorbers," an organization composed of automobile news writers and advertising solicitors connected with the Quaker City dailies

Harry T. Clinton has resigned his charge of the publicity and advertising department of the Association of Licensed Automobile Manufacturers. The resignation took effect Sept. 1. Mr. Clinton has accepted the position of secretary to the contest committee of the Automobile Club of America. This, of course, necessitated his resignation as a member of the A. A. A. racing board.

F. J. Fisher will assume Sept. 1 the offices of secretary and treasurer of the Fisher Body Company of Detroit, Mich., and will also have charge of the general management. Mr. Fisher was formerly with the C. R. Wilson Body Company, also of Detroit.

H. M. Coale, for the past four years connected in various capacities with the Auto-Car Company, of Ardmore, Pa., has been appointed manager of the recently re-established branch house of the company at 249 North Broad street, Philadelphia.

A. G. Southworth has taken the New York agency of the Buick, and will handle it from 1733-35 Broadway, where formerly he represented the Pope Manufacturing Company.

S. A. Miles, general manager of the N. A. A. M., has returned to New York City after his usual Summer vacation at Christmas Cove, Me. He will visit Chicago in the near future on Chicago show matters.

William A. Rutz, formerly New England traveling representative of the Continental Caoutchouc Company, has joined the New Departure Company of Bristol and will cover the western territory.

Alfred Reeves, general manager of the A. M. C. M. A., returned to New York this week from a fortnight's rest on the Maine coast, much improved in health.

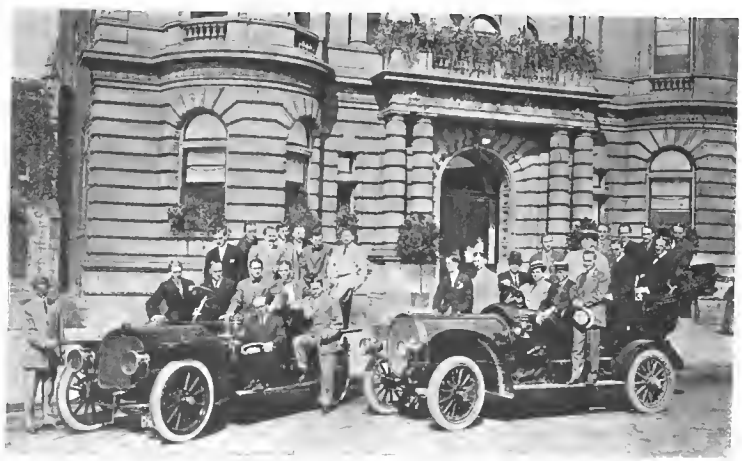
G & J TIRE MEN MEET.

INDIANAPOLIS, IND., Sept. 1.—The G & J Tire Company had a most successful conference of its army of representatives, all parts of the country being represented, as the concern has eighteen branches and distributing agents.

During the three days beginning August 26 there were meetings and entertainments of various kinds. President B. C. Dowse made the address of welcome, and announced that the great demand for G & J tires had compelled an increase of capacity, and the company had purchased a large amount of factory equipment which would be installed in the near future.

Matters of interest taken up and discussed included the 1909 prices and the new lines which will be added. These will be confined to motorcycle and bicycle tires. The G & J factory has been in operation twenty-four hours a day all this season, with its full capacity of workmen.

Among those who spoke during the various sessions were: E. S. Benson, secretary and treasurer; G. G. Hamilton, sales manager; H. H. Halloway, office manager; H. W. Waite, factory superintendent, and George W. Stephens, advertising manager.



Those Who Attended the G & J Conference.

First row (sitting) from left to right: W. B. Harding, purchasing agent; G. H. Hamilton, sales manager; H. A. Githens, general factory representative; B. D. Dowse, president; E. S. Benson, secretary and treasurer; H. W. Waite, factory superintendent; H. H. Holloway, office manager. Second row (standing): H. B. Dwelle, order clerk; C. H. Mead, Portland, Ore.; W. C. Dowse, Chicago, Ill.; F. A. Drake, Philadelphia, Pa.; F. Burodin, Philadelphia, Pa.; F. S. Cropley, Chicago, Ill.; T. V. Graves, Chicago, Ill.; D. B. Price, Boston, Mass.; Saul Levy, Buffalo, N. Y.; D. E. Foote, Cleveland, Ohio; G. W. Stevens, advertising manager; W. K. Philip, New York, N. Y.; C. L. Elyea, Atlanta, Ga.; C. E. Starratt, San Francisco, Cal.; E. H. Sprague, Omaha, Neb. Third row (standing): C. S. Munson, Detroit, Mich.; G. M. West, Los Angeles, Cal.; H. G. Plant, Minneapolis, Minn.; H. H. Hubbard, Indianapolis.

INFORMATION FOR AUTO USERS

New Herz Magneto.—In the design of the Herz high-tension magneto, the manufacturers, Herz & Company, 203 Lafayette street, New York City, have worked very closely to a theoretical ideal, with the view of obtaining the

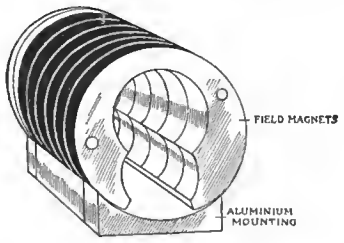


Fig. 1.

highest possible electrical efficiency. There is a marked saving in weight, the whole machine being reduced to a minimum in size, and it is claimed there is a remarkable sparking power at the slowest speed of rotation. A glance at the diagram of the complete machine (Fig. 5) shows that the construction does not follow conventional practice. The well-known "horseshoe" or U-shaped field magnets are absent, and a cylindrical, smooth, all-enclosed field system is seen

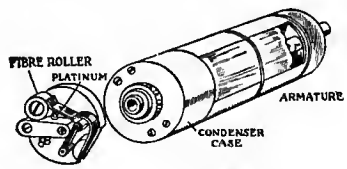

Fig. 3. *Fig. 2.*

instead. The magnet system is in reality composed of several flat steel rings clamped together, their surfaces being ground with extreme accuracy. The next striking feature is that the usual independent pole pieces are entirely dispensed with. In the Herz magneto, the "one-piece" ideal is obtained quite simply, the armature space being bored out of the rings.

The magnet system of the Herz is shown in Fig. 1. The armature, which

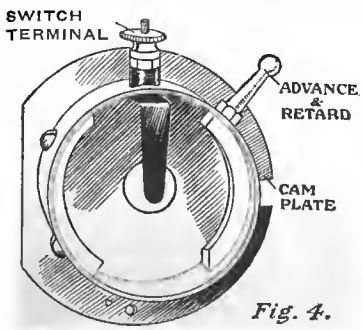

Fig. 4.

is of conventional design, is shown in Fig. 2. The bearings are of the ball type, and the ball cage is detachable from the outer ball race. The contact make and break device, shown in Fig. 3, is arranged as a complete detachable unit, fitted to the armature shaft by means of a small key way and feather. The contact device consists of three parts: (1) a curved spring having a platinum contact at one end; (2) a small steel piece or block set slantwise, carrying an adjustable platinum contact; (3) a small hard fiber roller, loosely centered on a pin. The contact maker turns round bodily with the armature, and in rotating the fiber roller strikes against two steel projections held in a case shown in Fig. 4, and thus the break occurs at the point of maximum induction twice per revolution, and the sparking current is induced in the secondary winding.

The high-tension end of the armature has mounted upon it a deeply recessed V insulating collar with a metallic sector within it at the right-hand end of

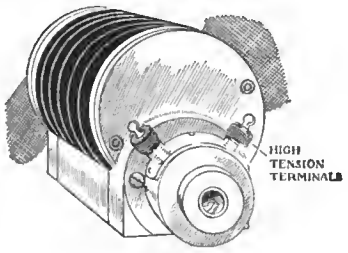

Fig. 5.

armature, which is not visible in the sketch, and upon this sector presses small carbon brushes for drawing off the high-tension current. The machine illustrated in Fig. 5 is a two-cylinder pattern, and in the four-cylinder pattern a high-tension distributer is combined. The casing of the machine is aluminum, forming a dust-tight, smooth and well-finished covering. The single-cylinder magneto weights four and one-fourth pounds, and the four-cylinder machine weighs seven pounds. Every part is made on the interchangeable system at the Herz European factory, and kept in stock by Herz & Company at their New York headquarters.

New Mufflers and Timers.—The Garage Equipment Company, 285 East Water street, Milwaukee, Wis., is just placing two new specialties on the market, the "Anti-Explo" muffler and the De' Paul timer. The distinguishing feature of the former from which it derives its name, is an automatic anti-explosion valve or special cut-out, consisting of a specially designed valve, which relieves the pressure before it reaches the muffler. It is constructed in the best manner throughout, the heads being of malleable iron, while the four tubes are of heavy sheet steel securely fastened at the seams. These tubes are perforated at opposite ends by numerous holes, thus allowing the gas to expand from one tube to the other very rapidly and causing no sound as it escapes from the muffler. It is made in sizes ranging from 6 by 16 inches up to 8 by 30 inches, either plain or with special cut-out valve and exhaust nozzle. The De' Paul timer is made of the best quality bronze, with special high-speed steel rotating spindle. It also has a specially designed, tempered steel roller contact, set by micrometer adjustment, so as to deliver an equal spark to all cylinders at any speed of the motor, thus preventing missed explosions and increasing the efficiency of the motor, besides saving the platinum points of the vibrators on the coils. It is made in sizes to fit all motors and from one to six cylinders. The com makes special types of timers for Ford and Buick cars.

A New Speedometer.—The Specialty Company, of New Yor cently been incorporated by a r men well known in the automo and among other articles they v facture the Peerless speedometer. strument has a mileage and maxir and a season and trip odomete distinguishing feature is the ste the indicator. Realizing the nee pair department for speedometers pany will maintain a shop equipp work, and will repair and r speedometer within twenty-four h

Simplicity Rectifier.—As th tion shows, this is an extremely compact piece of apparatus tha placed anywhere. It is intended an alternating current in order tion accumulators may be charge and is the product of the Auto Manufacturing Company, 2366-2 hill Road, Cleveland, O. No tir cial preparation is required to this is accomplished simply by the switch, and an accidental fail current can do no harm to eith tery or the rectifier, as the batt discharge through the latter, a immediately resume operations current is on again. VOL. XIX NEW YORK—THURSDAY, SEPTEMBER 10, 1908—CHICAGO No. 11

THE AUTOMOBILE

LOWELL'S RACE HAS A FOREIGN CAR WINNER

By C. F. MARDEN.

LOWELL, MASS., Sept. 7.—Louis P. Strang added more laurels to the crown of victory to-day by winning the 254.4-mile Lowell road race on a 10.6-mile circuit in 4 hours 42 minutes 34 seconds. He drove the 60-horsepower Isotta Fraschini, the same make in which he won the Savannah and Briarcliff races, and averaged 53.6 miles an hour, faster than had been thought possible. Strang was accompanied by Leo Anderson as mechanician. The car ran perfect from start to finish, and Strang, using Michelin tires, had little trouble, being bothered in this respect not at all until near the finish in the last lap. Strang drove a magnificent race, taking the bad corners easily, and dashing up the stretch of boulevard at remarkable speed. He had four laps on his nearest competitor, the Buick driven by Burman, which, however, was disqualified in the twenty-first round, the referee allowing a protest that was filed by entrants of other cars. The protest was based on the claim that the conditions of the race had been violated, outside help being employed in making repairs on the car. The Buick was stopped at the end of the twenty-first lap, and the time from the twelfth lap was wiped out. The Buick's elapsed time for twenty rounds was 4:41:04. The race was well managed. There was only one arrest—a negro boy being taken up for gambling, and there were no injuries of a serious nature. The crowd kept off the track. Some cars were exceedingly unfortunate with tires, the Fiat and the Berliet being especially troubled in this respect and losing much time.

Second place was won by the 60-horsepower Berliet, entered by the Park Square Auto Station of Boston, and driven by Harry F. Grant. This car had much tire trouble, but depsite this averaged 40.7 miles an hour. It was Grant's first road race, and he received much well-deserved praise for his good work.

The Knox finished third, its elapsed time being 6:33:29. The Fiat was fourth in 6:38:32. The Knox and Fiat had a close race in the last lap, and the excitement held the crowd better than in any previous important road race in this country.

Strang and Winning Isotta in Full Cry.

Weather and road conditions could not have been better. Sunday there was a rain, and it beat down the roads, which already had been oiled and rolled until they were as near perfect as possible. The rain also improved the edges, making the conditions for passing on the back stretch much better than they otherwise would have been. Following the rain came a brisk wind, and the sun rose bright in the morning, ushering in an ideal September day, the sky being cloudless when the hour of starting approached. At that time there was a tremendous crowd all along the circuit of 10.6 miles. The five miles of boulevard was double lined on one side with cars, and on the other side was a dense mass of humanity that led, some into Lowell by train, trolley, and on foot, from all over New England. The big grandstand filled more slowly, as seats there were reserved.

Among the early comers was Congressman Butler Ames, the donor of the trophy. He occupied a box in the front of the grandstand, and in front of his box, opposite the starting line, was the massive silver cup for which the seven cars raced the 254.4 miles, twenty-four times around the circuit. The course was well fenced, and a large force of Lowell police and several hundred militiamen, sworn in as special officers, kept back the crowd very efficiently. The grandstand was admirably located, commanding a view of nearly a mile down the boulevard and half as far in the other direction.

The cars were early at the course, and Starter Wagner had them lined up in order a full half-hour before the first car was due to start. In front was the Simplex, driven by Frank Lescault, with Thomas Colter as mechanician. In order were the Fiat, driven by George H. Robertson, with Glen Ethredge as mechanician; Lewis Strang and his Isotta had Leo Anderson as his companion; the Buick was fourth in line, with R. Burman at the wheel and John H. Le Cain by his side. Fifth place, that was to have been occupied by Al. Poole's Isotta, was empty, but Poole was in the grandstand to witness the race, despite his broken col-

Berliet "60," Which Had Much Tire Trouble, but Landed in Second Place in Good Style, a Novice at the Wheel.

lar bone, received in the accident that put his car out of commission Saturday. The smaller Knox was sixth, William Bourgne driver, Jeremiah W. Lynch mechanician. The larger Knox, with Charles Basle at the wheel and accompanied by Edward A. Burns, was No. 7. Last was the six-cylinder Berliet driven by H. F. Grant, with Frank H. Lee as mechanician.

How the Contestants Got Away at the Start.

It was 9:55 when the Simplex engine was started and she swung into position for the start. There was lacking much of the spectacular effect of the start of a Vanderbilt Cup race; there was no weak morning light, only the full sunlight. But to the spectators who had had good breakfasts the change was agreeable. Minute by minute slipped by, and at exactly 10 o'clock Starter Wagner gave the word and the big grey Simplex was on its journey.

In regular order at one-minute intervals the Fiat, Isotta, Buick, two Knoxes, and Berliet followed up the broad boulevard. Time was allowed for No. 5, so there was a two-minute interval between the Buick and the first Knox. All got away in first-class shape. Except the Berliet, each car had a bonnet. There was an interval of a few minutes, then came the familiar cry, "Car coming! Car coming!" the bugle blew, and at 10:12 the Simplex flashed by, having made the first round in 12:21, or better than 50 miles an hour. The Fiat was close behind, passing 10:122-3, making the round in 11:43. The Isotta had gained a little and was working well when Strang flew by in third place, making the circuit in 11:42. The Buick completed the round in 13:33 and the No. 6 Knox in 14:06. The No. 7 Knox broke down at the upper turn and was delayed several minutes, being passed by the Berliet, which also stopped a little further on. The Simplex, Fiat and Isotta passed the Knox and Berliet, the Simplex finishing the second round at 10:24:35. Its elapsed time for 21.2 miles was 24:35. The Fiat's time was 23:45, and the Isotta's 23:25. This put the Strang Isotta in the lead on time. The Buick completed the second round just after 10:30 o'clock, its elapsed time being 25:26. The No. 6 Knox made the second round in 26:20. The No. 7 Knox completed the first round at 10:33:57, but was not running well.

Going the third round, Strang passed Lescault and Robertson and took the lead. With great applause Strang went by at 10:36:25, his elapsed time for 31.8 miles being 34:25. The Simplex passed at 10:36:50, its elapsed time being 36:60. Tl stopped just beyond the upper turn, and was passed on th stretch by the Buick, its time for three rounds being 38:

The Berliet finished its first round at 10:43:25. The Knox made the three rounds in 41:28. The Isotta, witl to the good over the Fiat, finished the fourth round, com 42.4 miles at 10:48:28. The Simplex finished four rou 10:48:56. Strang had gained three seconds over his opponent in this round and his car was running fine. T 7 Knox finished three rounds at 10:51:18, its elapsed tim 45:18. The Buick, in third place, finished four rounds at 10 The Berliet completed two rounds at 10:55:15, and the Knox four rounds at 10:58:41.

Stirring Finishes in the Early Rounds of the Rac

Robertson had his Fiat going again, and started to m the handicap he was under. At 11:00:06 he finished th lap. The Simplex, finishing the fifth round of 53 mil close behind, having passed the Isotta. The Simplex time was 1:01:06. The Isotta's time for five rounds wa The Buick passed at 11:05:21. Robertson had more trou was delayed only briefly. The Berliet had lost a tire and with the off rear tire gone at 11:09:08. The Fiat finishe rounds in 1:08:23. The Isotta finished six rounds—63.(or one-fourth of the race—at 11:11:59. The Simplex six rounds at 11:13:18. The Isotta made 53 miles in t hour, and was still in the lead. The Buick finished six in 1:59:49, and the Fiat four rounds in 1:19:56. With t one-quarter finished, the Isotta led, the Simplex was and the Buick third. The fastest lap was 10:53, made Isotta in the sixth round.

Driving in his best style and with his car running like Strang made seven rounds (74.2 miles) in 1:21:48. Tl plex made seven laps in 1:28:53, having lost time to the The Buick went up into second place in the seventh elapsed time being 1:27:27. The Fiat came along on lap at 11:33:05, being more than two laps behind the The Isotta finishing eight laps (84.8 miles) and the No. finishing four laps came close together. Strang's elaps was 1:33:28. Lescault, with the Simplex, passed at 1 and Burman's Buick at 11:42:27. Grant, having chang got going again, and at 11:42:40 completed four round

Fiat came close behind, finishing six laps, and the No. 6 Knox was near it, finishing five laps. Strang finished the 95.4 miles of nine laps at 11:46:45, his elapsed time being 1:44:45. The Buick was six minutes behind, and the Simplex two minutes behind the Buick.

Strang Steadily Increased His Lead as Race Progressed.

With a lead of 5 minutes and 19 seconds, the Isotta began the eleventh lap, having made 10.6 miles in 116 min. 35 sec. The Simplex made the distance in 124 min. 56 sec., and the Buick in 122 min. 32 sec. These three cars had about 30 miles lead over the Fiat, which was fourth. At 12:05:55, when the Berliet passed, all the cars had finished six laps, or a quarter of the race. The order was: Isotta, Simplex, Buick, Fiat, No. 6 Knox, No. 7 Knox, and Berliet.

At 12:10:09 Strang finished the eleventh round (116.6 miles). His elapsed time was 2:08:09. The Buick's time was 2:14:17, and the Simplex's 2:16:54. Strang finished half the race (12 laps—127.2 miles) in 2:20:22, or 140 min. 22 sec. The Simplex got a flat tire and stopped to change just in front of the grandstand, giving the crowd a welcome diversion. The Buick passed with the rear wheel wobbling badly. The Simplex's time for twelve rounds was 2:28:52, the Buick's 2:26:53. The Fiat had tire trouble and was delayed for a long time, and the race seemed to lie easily in Strang's hands, as he was gaining every lap. He finished thirteen rounds in 2:31:46, at 12:33:46 o'clock. The two Knox cars and the Fiat were in the ninth lap and the Berliet in the eighth. The No. 6 Knox had crawled up into fourth place and the Berliet into the fifth, the Fiat dropping to sixth. In the fourteenth round Strang lapped the Buick and the Simplex. His time for fourteen rounds (148.4 miles) was 2:44:12. The Buick had trouble, and the Simplex went up to second place, completing thirteen rounds in 2:48:59. The Berliet made nine laps in 2:42:44 and the Fiat the same distance in 2:49:33.

At 12:58:06 Strang's Isotta flew by, ending its fifteenth round. Its elapsed time was 2:56:06. Lescault's Simplex made fourteen rounds in 3:04:08, the No. 6 Knox eleven rounds in 2:55:24, the Fiat ten rounds in 3:02:01, and the Berliet ten rounds in 2:54:21. At 1:09:10, the Buick having made repairs, completed the thirteenth round, its elapsed time being 3:06:10. Strang finished his sixteenth round (169.6 miles) in 3:07:58. The No. 6 Knox finished its twelfth round in 3:07:48. The Simplex completed fifteen rounds in 3:16:11 and was running strongly. Strang dashed by the stand and began his eighteenth lap, having made 180.2 miles in 3:19:37.

Just before 1:30 o'clock the first real brush of the race visible at the grandstand occurred. Lescault's Simplex and Robertson's Fiat came tearing up the broad boulevard side by side. They were almost neck and neck, but Lescault had speed in reserve, and passed his opponent in front of the stand. The Simplex finished sixteen rounds in 3:28:11 and the Fiat twelve rounds in 3:27:10. The Buick made fifteen rounds in 3:29:35.

Strang finished eighteen rounds, three-quarters of the race, covering 190.8 miles in 3:31:16. His machine was running beautifully, and he had two laps on the Simplex and three on the Buick.

Excitement Ran High as Race Neared the Finish.

In making the seventeenth round the Simplex had pulled away from the Fiat and led him by several hundred yards when they again went by the tape. The Simplex's time for 180.2 miles was 3:40:19; that of the Fiat for 137.8 miles was 3:40:59. Strang finished nineteen rounds, making 201.4 miles, in 3:42:43. The Buick was just ahead, completing its sixteenth round. Strang had averaged nearly 55 miles an hour from the start. There was a pretty race up the stretch when Strang finished the twentieth lap, closely pursued by the Buick finishing its seventeenth lap. The little Buick had become a favorite, and the crowd gave Burman a cheer as he went by in the Isotta's dust.

The Fiat finished fourteen rounds in 3:52:55. The Isotta finished twenty laps (212 miles) in 3:54:05. In the fifteenth lap Robertson drove hard and nearly caught Lescault, but he failed to do so, his motor not working first-class. They went up the stretch neck and neck, and Strang was close behind in his twenty-first lap. The Simplex passed at 2:06:54 o'clock, the Fiat at 2:07:01, and the Isotta at 2:07:50. Soon after passing the grandstand the Simplex blew a cylinder. The Buick finished eighteen laps at 2:09:34, its elapsed time being 4:06:34. The Berliet, having more tire trouble, passed at the end of the fifteenth round and threw a forward shoe. It scattered the crowd and the police, but one small boy was so unfortunate as to be hit. He was not hurt. The Berliet and the Fiat were especially sufferers from tire trouble. At 2:19:33 Strang again

tore by the tape, making twenty-two laps (233.2 miles) in and, as it seemed, only a few minutes later he rushed stretch again, and Fred Wagner gave him the green f that he was beginning the last lap. His elapsed time for three laps (243.8 miles) was 4:30:49. Though he had practically won, Strang did not let up his pace, and at he finished a winner, but on a flat tire. His elapsed t 4:42:34. Strang was given a fine round of applause as ished.

Four cars were to finish, and the crowd was remark tient in remaining in place, the course being kept clear remaining cars. The Simplex was out with a broken and the No. 7 Knox had withdrawn, losing a wheel in th lap, leaving only the Fiat, Buick, No. 6 Knox, and the B fight it out. A protest was filed against the Buick by of the Fiat, Knox, and Berliet, claiming that it was repai outside help, the radiator being changed. The protest w under advisement, and later allowed by the judges.

Interesting Features of the Finishing Laps.

When Strang finished the Fiat and Berliet were in th eenth lap, the Knox in the nineteenth, and the Buick twenty-first. The Buick was disqualified because of ir of the rules in having outside assistance in making repair man was flagged when he finished the twenty-first round time after the twelfth was thrown out. This put the second, the No. 6 Knox third, and the Fiat fourth at th ning of the twentieth lap. The Berliet finished the t lap in 5:18:14, the Knox in 5:23:28, and the Fiat in 5:2 the next lap the Berliet gained a little on the Knox. T liet's elapsed time was 5:30:31, and the Knox's 5:36:5 Knox in turn increased its lead on the Fiat, the Fiat's time being 5:43:10. The Berliet covered twenty-two 5:42:57, not only holding its position, but gaining on th the elapsed time of which was 5:57:07. The Fiat hac up a little, and its elapsed time was 6:01:48. The Ber running smoothly as it entered the final lap and on th part of the course lapped both the Knox and the F elapsed time for twenty-three rounds was 5:56:11. In t stretch the Berliet had trouble and was passed by the K the Fiat. The Berliet, however, was only temporarily and soon was going again.

At 4:21:58 the 60-horsepower Berliet flashed by, finis race in second place. Its elapsed time was 6:14:58. Th had done excellent work against odds, and Grant had heady race. The Knox led the Fiat by about two minute beginning of the last lap. They made a great duel the way around, and they swung into the stretch close t the Knox having a little the better of it. There was a tussle up the boulevard, but the Knox held its lead and in third place, its elapsed time being 6:33:29. The F fourth, finishing with a flat forward tire. Its elapsed ti 6:38:32. This ended Lowell's first and very successful r

This evening President John O. Heinze and the other of the Lowell Automobile Club entertained the drivers, icians, and officials at a complimentary dinner at the Country Club, at which the trophy was presented. The mac Valley course was duly boomed as the scene of fut portant road races, including the 1909 Grand Prix.

MORRIS PARK AS AN AIRSHIP TRACK

The Morris Park race track, in New York City, o scene of automobile record-breaking, will now be devoted ilar attempts by flying machines. The recently formed nautic Society has secured the use of the track for the us members, together with the grandstand and outbuildings will provide ample storage room. On Labor Day Wilbur l ball, vice-president of the society, gave his helicopter an on the grounds. The machine was rolled around for ins and its motor was run for a while, but no attempt was r send it into the air.

No. 6 Knox Passing the Big Grand Stand, Where the Excellent Arrangements for Spectators Were Plainly Apparent.

HOW THEY WERE MECHANICALLY CONSTITUTED

By CHARLES B. HAYWARD.

LOWELL, Mass., Sept. 7.—Strang's *Isotta* three-time winner, which he drove to victory to-day with the same clock-like regularity that distinguished his performances earlier in the year at Savannah and Briarcliff, has been in the limelight so much during the past half year that its mechanical details are more or less a matter of common knowledge. It has a four-cylinder vertical engine, the metric dimensions of which are the equivalent of 5 7-8 bore by 5 1-2 stroke, thus making it a high-speed motor, while it is rated at 60-horsepower, though, needless to add, it is capable of an output considerably in excess of this figure. An Eisemann magneto is the sole provision for ignition, lubrication being effected by the exhaust pressure, a 12-gallon tank of lubricating oil being carried between the fuel supply tank and the driver's seat. A carbureter of special Isotta design, which, however, does not differ radically from accepted standards, a centrifugal pump and honeycomb radiator complete the motor details. Transmission is through a four-speed sliding gear of the selective type to double side chains, the gear ratio being 2 to 1, which accounts in part for the excellent speed performance of the car as some of the others were geared lower. The wheel base is 122 inches and the tire equipment is Michelin on dismountable rims of the same make. Throughout the 250-mile swing-round the endless turns of the 10-mile circuit, Strang never lost a moment through mechanical trouble, while the goddess of tire fates was equally amiable, his only Michelin mishap being a puncture on which he finished as fast as if all four were still good.

Berliet No. 8, which sprung the surprise of the day by finishing second, after having had endless tire trouble, was the only representative of the six-cylinder type entered. Its six cylinders are cast in pairs and measure 4 3-4 by 5 inches, giving it a rating of 60-horsepower, which is conservative, to judge from its speed

The Buick, Which Met with Disqualification.

The Butler Ames Trophy and Its Donor.

abilities. It was one of the two longest cars in the contest, and its wheelbase of 126 inches proved an advantage, rather than a hindrance, in taking the numerous turns. A carbureter of special American Locomotive design takes care of this essential, while lubrication is by means of a constant circulating system. Fuel feed is by pressure, ignition by Bosch high-tension magneto, a honeycomb radiator and centrifugal pump providing for the cooling. A four-speed selectively operated gear set and side chains complete the transmission. Diamonds on Continental dismountable rims form the tire equipment.

Knox team, Nos. 6 and 7, were extremely businesslike, the smaller showing its mettle by finishing third. No. 6 was the small Knox, having a four-cylinder engine measuring 4 7-8 by 4 3-4 inches and rated at 40-horsepower, its wheelbase of 102 inches making it the smallest car entered. The motor is of the new water-cooled valves-in-the-head type of Knox for 1909, and is lubricated by a special oil circulating system. A Splitdorf magneto, supplemented by a set of accumulators and four unit Splitdorf coil provided for the ignition. The tire equipment consisted of Fisk on the Fisk dismountable rims. With the exception of its difference in size and its side chain drive, the same description applies to a great extent to the No. 7 Knox, the motor dimensions of which are 5 1-2 by 5 1-2 inches, while its rating is 60-horsepower. Its wheelbase is 106 inches and it also had Fisk tire equipment. Both were fitted with special shock absorbers.

Simplex No. 1, which was a sure second up to within two or three of the short laps of the finish, when, according to report, it cracked a cylinder and had to retire, is a 50-horsepower four-cylinder machine which distinguished itself at the Briarcliff last Spring. Its cylinder dimensions are 5 3-4 inches "square" and its motor turns over at a rate, which, with the car's high gear ratio, made it pass the stand on the boulevard straightaway at a pace that made Lescault an equal favorite with Strang from the spectacular point of view. It was one of the lo competing, its wheelbase of 126 inches being the sa Berliet and exceeding the closest approach to this by foot, and, like most the others, its semi-elliptic springs fully wrapped. In addition to this, it was equipped v fault-Hartford shock absorbers. Drive is through a selective sliding gear set to double chains. Its tire consisted of Michelins on Michelin dismountable rims.

Of the seven contestants which lined up this mo No. 2 **Fiat** is the only one having low-tension ignitio magneto being used. It is a 60-horsepower, four-cy chine, its dimensions being 140 by 135 millimeters, ar Isotta, having a bore exceeding the length of its str accounts for its speed of 1,400 to 1,500 r.p.m. C expectation, its performance was a disappointment first, and its motor troubles, apparent early in the ra more pronounced toward the end, when it seemed to on three cylinders only. Like both the Simplex and transmission consists of a four-speed selective gear chain drive. It was equipped with Continental tire Continental ready-inflated replacements.

The performance of the little **Buick** No. 4 proved surprise. With its 4 5-8 by 5 inch four-cylinder m at 40-horsepower, it maintained a speed and regulari ning that was amazing. For ignition, a Remy magnet ployed, supplemented by a set of Duro accumulators necticut coils. It was geared at 2 1-2 to 1 and was two shaft-driven cars in the race. Before the latte over, however, it showed signs of giving way under Its radiator bearing No. 4 was replaced by a new one were signs of rear axle trouble which gradually bec and eventually prevented a successful termination of a most creditable showing. However, it was disqual referee for receiving assistance on the twelfth lap.

Fiat "60," Which Finished in Fourth Place.

Four Notables—Owen, Wagner, Fortescue, Spe

WILDWOOD HAS GOOD SPORT WITH ELEVENTH-HOUR FIELD

WILDWOOD-BY-THE-SEA, N. J., Sept. 7.—Steam triumphed over gasoline in the three principal events of the closing meet of the Motor Club of Wildwood over the mile course on the Central avenue boulevard, the Stanley steamer driven by D. Walter Harper flashing over the tape by a comfortable margin in each instance. But the field was not a representative one by any means, from the gasoline standpoint, the Parkin and the Sharp-Arrow, both comparative newcomers in the racing field, being the only cars to approach the steamer's time.

Indeed, there was a woeful dearth of cars of all kinds. So scarce were they, indeed, that the committee in charge had not a sufficient number of entries this morning to warrant the publication of a program, and had it not been for a number of Philadelphia visitors who post-entried their cars, it is quite likely that there would have been no races. Arthur Hammerstein, a relative of the celebrated impresario, entered his Mercedes as a stop-gap; John Wilkinson did likewise with his Packard, and young John Wanamaker, Jr., with a car of similar make. And they entered almost every event, too; otherwise the entire program would have been a series of triangular duels between the Stanley, Parkin, and Sharp-Arrow cars, the only ones that were stripped for the fray.

W. Wayne Davis, the starter, helped out the program by putting in a special match race of Mathesons, and the Stanley contingent did likewise with a trio of steam runabouts belonging to visitors.

And yet the sport was well worth while. The course was never in better shape, the weather was excellent, and the crowd enormous. After the Stanley had annexed the flying start free-for-all, the committee repeated with a standing start with the same field—that helped some, too.

The real battle of the day came in the mile time trials, the winner of which annexed the choicest bit of plunder ever hung up in these parts—a building lot worth $1,000 at Wildwood Crest. Hammerstein and his Mercedes led off with a modest 1:06 3-5, and then Harper cinched things with a :47 2-5 trip (course record, :42 3-5, held by Schill's 120-horsepower Fiat). That was fast enough to hold the others safe, for the Sharp-Arrow could do no better than :51 1-5, the Parkin :51 3-5, and the Wilkinson Packard :57 2-5.

It was the same story in the kilometer time trials. The Mercedes again led off—time :41 flat. Frank Yerger drove his "army dispatch" Studebaker over the distance in :41 2-5. Then Harper again choked off all opposition with a Stanley trip in :29 1-5, although Joe Parkin came near his time with a dash in an even half minute.

One of the most exciting races of the day was a handicap for touring cars, the marks being calculated from the performances of the cars in the previous events—a special ruling calling for the disqualification of any car that did the mile more than five seconds faster than its previous best time. Arthur Hammerstein's Mercedes was the long-mark car, and the 19 seconds' start proved too much for the Stanley (scratch) to overcome, the steamer finishing a bad third.

The prizes were distributed on the boardwalk by the Mayor in the evening, and what looked like a rank fiasco early in the morning was voted a good day's sport by the spectators. The summary:

MATCH RACE, MATHESON TOURING CARS.

1.	Matheson	Willie Houpt	1:22
2.	Matheson	Frank Yerger	1:27
3.	Matheson	Louis Taubel	....

FREE-FOR-ALL (Flying Start).

1.	Stanley	D. Walter Harper	:55 2-5
2.	Parkin	Joe Parkin, Jr.	:58
3.	Sharp-Arrow	Wm. Sharp	:59

4.	Sharp-Arrow	(4 sec.)	Wm. Sharp	....
5.	Studebaker	(18 sec.)	Frank Yerger	....
6.	Packard	(10 sec.)	John Wilkinson	....

MILE TIME TRIALS (For $1,000 Lot.)

1.	Stanley	D. Walter Harper	:47 2-5
2.	Sharp-Arrow	Wm. Sharp	:51 1-5
3.	Parkin	Joe Parkin, Jr.	:51 3-5
4.	Packard	John Wilkinson	:57 2-5
5.	Studebaker	Frank Yerger	1:05 3-5
6.	Mercedes	Arthur Hammerstein	1:06 3-5

KILOMETER TIME TRIALS.

1.	Stanley	D. Walter Harper	:29 1-5
2.	Parkin	Joe Parkin, Jr.	:30
3.	Mercedes	Arthur Hammerstein	:41
4.	Studebaker	Frank Yerger	:41 1-5

TRACY FINDS PARKWAY GOOD FOR 90 MILES AN HOUR

THAT the cement stretch now in course of construction as a part of the Vanderbilt Cup race course has speed capabilities of 90 miles an hour was convincingly proved by Joseph Tracy in a series of sprints over it last Friday. The car used for the test was the Locomobile in which Mr. Tracy made the fastest lap in the Vanderbilt contest in 1906. Timed by Charles J. Dieges and H. O. von Schuckman, recognized sprint clocking experts, half-miles were negotiated in 23 and 24 seconds and quarter-miles in 11 and 10 4-5 seconds. The latter shows a rate of approximately 90 miles an hour.

Mr. Tracy was enthusiastic over the cement section of the course, 8 miles of the total 11 miles which have practically been completed. He thinks the curves well banked and capable of negotiation at a mile a minute, though the engineers have calculated only upon 40 miles an hour.

As a racing veteran, Mr. Tracy's opinion of the new speed stretch is valuable. He also had some interesting comments to make. "The cement highway makes an excellent racing road," said he, because it is absolutely dustless, and on account of the grayish color it does not blind the drivers even in the glaring sun, and is very easy to follow even at top speed. There are new sensations also in driving over the cement highway which one does not meet on the ordinary State or country road. There is quite as much bouncing and swaying of the car as you find on the dirt road—possibly a little more—but there is not the slightest tendency to skid, even on the turns, which are only banked, the engineers tell me, for a speed of 40 miles an hour. I took several of those turns which have been completed at the rate of 60 miles an hour, and found the banking ample. Over the straight stretches I think I broke my best record in the last Vanderbilt race. That was about 106 miles an hour for a quarter of a mile stretch, which we measured off near our racing headquarters at Lakeville."

It is not improbable that Mr. Tracy will drive in the Vanderbilt.

LATEST NEWS ABOUT RACE FOR THE VANDERBILT C

PRESENT indications are that the 1908 Vanderbilt Cup race, scheduled for October 24, on Long Island, will have a preponderance of American participants, with the foreign element secondary in importance. The latest information available indicates that a considerable number of American makers will make entries in the near future, while others may hold back until the actual closing of the list on October 1.

William K. Vanderbilt, Jr., donor of the famous cup, returned from Europe on Tuesday last, following which there were several conferences and a meeting of the cup commission yesterday afternoon. The whole situation was carefully canvassed, and there is no question about the holding of the race, providing the American manufacturers immediately come forward with the requisite number of entries—a situation which seems to be assured beyond question.

One Thomas racing car was entered this week, and it is anticipated that a second Thomas car will also be named very shortly. Locomobile, Pennsylvania, Roebling, Pope-Hartford, Frayer-Miller and Chalmers-Detroit are among the other probable sources of early candidates. Outside of a couple of firms, it is an admitted fact that the foreign makers have lost interest in American racing, coincident with the fact that the American market is no longer a remunerative one, except for a couple of makes.

Since the first announcement of the Vanderbilt Cup course there has been a notcworthy change in the course. At the western cnd the cars will turn off from the Jericho road into the Old Westbury road, and travel south in the direction of the cement stretch until they reach the old country road. To connect the latter with the cement stretch the parkway engineers are building a new highway of over a mile in lengh to connect the western end of the cement with the southern e Old Westbury road, thus doing away with two sharp climinating Whaleneck avenue.

The engineers have complained that so many aut are visiting the parkway as to interfere with the work ingly Chairman Thompson has found it necessary t order against the use of the parkway stretches by vis the work is nearer to completion.

Work on the Vanderbilt stretch of the parkway nearing completion. About eight miles of the cemen in all has been laid, and nearly all of the bridges at i county roads and railroads are ready for the cemen These bridges are formed by a solid cement abut enough to permit a steam train or a load of loose h under the new cement parkway. The tops of the abu connected by heavy steel girders, such as are used to s roof of the Manhattan subway, and around these wooden mold is built and the cement and crushed poured in until the desired level is reached, thus n bridges at all intersecting roads practically solid cen and stone. The longest bridge is 90 feet. This is th Central Park, where the highway begins to rise abo before it reaches the Long Island Railroad tracks. ments are about 35 feet high at this point, and the will pass over railway trains and vehicles which trave public highway, so that it will be possible while the progress to run trains on this branch on regular sch none of the country traffic will be interrupted in the le

The Long Island Railroad has made preparation tracks from the Hempstead branch into the back of stand to insure convenient service.

DE PALMA NOW HOLDS MILE TRACK RECORD.

MINNEAPOLIS, MINN., Sept. 5.—Walter Christie's world's record of 52 seconds, for a circular track, was lowered a full second to-day, in the speed trials run in connection with the Minnesota State Fair automobile races. Ralph De Palma, driving his Fiat car, put the mark at 51 seconds, and in subsequent attempts to equal the new record, Christie did 52 1-4.

De Palma's performance was so sensational as to arouse the 30,000 spectators who filled the grandstands, bleachers, and paddock, to the highest pitch of enthusiasm. Christie had made the first trial at the record, hitting a mark of 52 1-2, and making a daring circuit of the track. De Palma followed him almost immediately, and the performance of the young driver of Cedrino's 90-horsepower speed car was the acme of daring.

He took the turns with almost no lessening of speed, and did not skid as much as Christie had done. De Palma's burst of speed in the home stretch was hair-raising. His time at the half was 26 flat, and he reduced this by a full second in negotiating the last half of the course. The announcement of the setting of a new record brought forth thundering cheers from the spectators, and Christie was among the first to congratulate the winner.

Christie later made another trial at the record, making a circuit of the track in 52 1-4 seconds. In a match race held after the speed trials, De Palma took two successive heats from Christie, his time being 3:04 and 3:01 4-5.

CLEVELAND RELIABILITY IN NOVEMBER.

CLEVELAND, Sept. 8.—Because of a conflict with the Chicago contest dates, the Cleveland reliability run has been postponed from October 7-9 to October 14-16, with a possibility that it may not be held until the very early part of November.

NAZZARO WINS BOLOGNA RACE WITH

BOLOGNA, Sept. 6.—The race for the florio trophy was won by Nazzaro and his Fiat, in the time of minutes 21 seconds for the 327.6 miles. This is at 74.3 miles an hour, and is a world's record. Only six seventeen starters finished, in the following order:

Nazzaro, Fiat, Italian.....
Trucco, De Dietrich, French.....
Cagno, Itala, Italian.....
Demogeot, Mors, French.....
Lancia, Fiat, Italian.....
Garcet, Clement, French.....

There were six Italian and eleven French cars in t these, 50 per cent. of the Italians and 27 per cent. of cars finished. Mishaps were numerous, but no seriou occurred. After the finish Nazzaro declared that thi his last race, as he is soon to marry a young lady of T A. C. A. has for some time advertised that Nazzaro w in the Grand Prize race at Savannah, but it looks as if due to be disappointed.

QUAKERITES HOPE FOR FAIRMOUNT

PHILADELPHIA, Sept. 7.—The managers of the pro mile stock car race, which they hope to make a featu month's Founder's Week celebration, will not hear defi next Thursday whether or not the use of thc alread ten-mile course in Fairmount Park will be granted t ertheless, they are going ahead with many of the pr just as if the desired permission was a matter of co delay has been due to the fact that a majority of the has been out of town, and that a quorum will be a bility until Thursday next, when the appeal of the Q Motor Club will come up for action.

SUGGESTIONS FOR THE MAN WHO DRIVES HIS CAR

By THOS. J. FAY, E. E., President Society of Automobile Engineers.

FROM the time a car is delivered (in good working order) into the hands of the purchaser, it is for him to cope with the difficulties that may arise. The extent of his success will depend upon:

(*a*) The quality of the car.
(*b*) The skill of the user.
(*c*) The extent of service.
(*d*) The roads traversed.

At all events, the user of a car will oftentimes find himself unable to quickly locate troubles, unless he follows some systematic course, along lines based on "the elimination of the known quantities."

The scheme here given takes into account the various cases likely to arise distinguishing between the "likely known quantities" and the conditions to be surmised, in view of them. No plan can be so complete as to leave nothing to be desired; but this has been devised in a manner general in its scope, and should prove adaptable to nearly all makes of cars.

It is not to be supposed that any one car will develop any considerable number of the troubles suggested. Some of them, however, might arise in connection with any car; and with so many possible troubles, it will prove difficult for the average autoist to quickly locate the trouble to be eradicated, especially under road conditions.

The remedies will, in most cases, suggest themselves. For the more difficult problems, reference must be had to chapters dealing with them. It would detract from the value of this scheme to add anything by way of advice or suggestions of procedure.

CASE NO. 1—THE MOTOR WILL NOT OPERATE.

Known Quantities.

(*a*) Ignition is in working order.
(*b*) Compression is normal.
(*c*) Carbureter is in normal condition.
(*d*) Exhaust valves seat properly.
(*e*) Inlet valves seat properly.
(*f*) Gasoline in the tank.
(*g*) No water in the gasoline.
(*h*) Gasoline supply valves open.
(*i*) Gasoline piping is clear.
(*j*) Mixture intake is tight.
(*k*) Carbureter control system is not deranged.
(*l*) Gasoline "tank pressure" is normal.
(*m*) No water in cylinders (due to defective casting).
(*n*) Cylinders not flooded with cylinder oil.
(*o*) Cylinders not flooded with gasoline.
(*p*) Timer is not loose on the shaft.

Unknown Quantities.

(*a*) Ignition is out of time. This is a condition that could not well obtain in a motor that had been performing in a satisfactory manner, up to the time of failure to operate, unless the gear driving the timer should shift enough to alter the timing. That is, assuming the timer itself is in good working order. It is possible that the brushes of the timer might be loosened in such a way as to alter the timing relation.

(*b*) The spark might show all the evidences of working, and not work under compression. This could follow a crack in the insulation (porcelain tube) so small as not to be noticed. It might also be due to an excessive spark gap; it must be remembered that a spark in the open air is not positive proof of a spark under compression in the cylinder of a motor. The higher the compression, the higher the resistance of the spark gap.

(*c*) If the car comes from the repair shop and fails to work satisfactorily, provided all the known quantities of Case No. 1 are as stated, it may be taken for granted that the timing gears were not put back with the teeth meshing in the manner to set the timer in the right relation for timing the spark. In such a case, it will be necessary to locate the teeth that should mesh for correct timing and shift the gear relative to the pinion in such a way as to correct the error.

(*d*) It is possible to experience trouble as a result of infected grease in the timer. Anything that would materially lower the resistance of the grease, as particles of metal, carbon or other conducting media, would tend to cause trouble.

(*e*) If the wiring is in bad shape, it will be possible to note a spark in the open air that might be very feeble or intermittent under compression, since it might be the case that the leakage across the wiring system would manifest itself with the compression and not show up with the spark gap in air.

(*f*) Carbureter troubles may be distinguished from ignition troubles by making an artificial mixture in the cylinders. Crank with the vents open until enough fresh air has been passed through the cylinders to assure complete scavenging; then by priming through the vents and turning the engine over with the ignition switched on, it will be possible to note if the spark and timing are truly in working order. If the cylinders fire with the priming, the carbureter wants adjusting in some way or other.

(*g*) If a car has been working, and after repairing, fails to work in the usual manner, assuming all the known quantities are as before stated, and the timer is in the correct relation and in good working order, it is probable that the camshaft has been put back with the teeth of the half time gears out of correct mesh. This will demand that the half-time gears be remeshed, in accord with the requirements.

(*h*) If a car has been working, and after repairs it fails to come up to the mark, then, provided the timer is properly related and the half time gears of the camshaft show that they are right, as regards meshing, it will be well to note if the cams are keyed on; if they are, and in the act of repairing one or more of them were put back wrong, the result would be undesirable.

(*i*) If a motor has been provided with a new camshaft, and the known conditions are all as before stated, failure to perform properly will denote that the key-way for the half time gear is not in the right place with respect to the markings on the gear; that is, if the gears show markings for the correct mesh and the same markings were held to in inserting the new camshaft.

CASE NO. 2—THE MOTOR WILL NOT OPERATE.

Known Quantities (involving the carbureter).

(*b*) Compression is normal.
(*a*) Ignition in working order.
(*c*) Exhaust valves seat properly.
(*d*) Inlet valves seat properly.
(*e*) Gasoline in tank.
(*f*) No water in gasoline.
(*g*) Gasoline supply valves open.
(*h*) Gasoline piping clear.
(*i*) Mixture intake tight.
(*j*) Carbureter control system is not deranged.
(*k*) Gasoline tank pressure is normal.
(*l*) No water in cylinders.
(*m*) Cylinders free of excess lubricating oil.
(*n*) Cylinders free of excess gasoline.
(o) Camshaft not changed in any way.
(*p*) Camshaft half time gears not changed in any way.
(*q*) Grease in timer not infected.
(*r*) Motor will start after scavenging and priming.

Unknown Quantities.

(*a*) Carbureter float punctured? (if of copper).
(*b*) Carbureter float "loggy"? (if of cork).
(*c*) Gasoline level too low?
(*d*) Gasoline level too high?
(*e*) Float-bowl valve leaking?
(*f*) Nozzle stopped up?
(*g*) Nozzle needle valve worn?
(*h*) Nozzle needle valve wants adjusting?
(*i*) Gasoline strainer clogged?
(*j*) Balance levers of float loose or stuck?
(*k*) Carbureter passageways clogged?
(*l*) Air valves out of adjustment?
(*m*) Valve springs weakened?
(*n*) Lost motion in valves?
(*o*) Valves not free?
(*p*) Leaky gasket at carbureter joint?
(*q*) Change in specific gravity of gasoline?
(*r*) Water in float-bowl?
(*s*) Air vent stopped up? (float-bowl).
(*t*) Float guide pin damaged?
(*u*) Gasoline pocket in the intake?
(*v*) Hole in nozzle too small?
(*w*) Hole in nozzle too large?
(*x*) Defect in hot air piping?
(*y*) Initial air opening excessive?

CASE NO. 3—THE MOTOR WILL NOT OPERATE.

Known Quantities (involving the compression).

(*a*) Ignition in working order.
(*b*) Carbureter in normal condition.
(*c*) Gasoline supply adequate.
(*d*) Compression cocks closed.
(*e*) Motor cranks free.
(*f*) Motor starts with difficulty.
(*g*) Weak on the power stroke.
(*h*) Power falls off overmuch.

Unknown Quantities.

(*a*) Considerable falling off of compression?
(*b*) Leaky inlet valves?
(*c*) Leaky exhaust valves?
(*d*) Worn piston rings?
(*e*) Worn cylinders?
(*f*) Valve stems deformed?
(*g*) Valve stems in tight holes?
(*h*) Valve stems gummed up?
(*i*) Valve seats pitted?
(*j*) Valve springs' temper drawn?
(*k*) Valve lift adjustment changed?
(*l*) Crack in cylinder?
(*m*) Piston rings broken?
(*n*) Piston rings in tight slots?
(*o*) Piston ring slots all in line?
(*p*) Cylinder head covers not tight?
(*q*) Crack in piston?
(*r*) Spark plugs not screwed in tight?
(*s*) Intake stopped up?
(*t*) Broken valve stem?

CASE NO. 4—MOTOR WILL NOT OPERATE.

Known Quantities (involving the ignition).

(*a*) Compression is normal.
(*b*) Carbureter in normal condition.
(*c*) Battery in good order.
(*d*) Wiring free from trouble (battery).
(*e*) Timer in good order.
(*f*) No spark at trembler.

Unknown Quantities (involving the ignition).

(*a*) Trembler contacts worn?
(*b*) Trembler contacts not stuck?
(*c*) Trembler not adjusted properly?
(*d*) Leak in primary wiring?
(*e*) Primary wiring open circuited?
(*f*) Primary coil short circuited?
(*g*) Primary electrodes partially short circuited?

CASE NO. 5—MOTOR WILL NOT OPERAT

Known Quantities (involving the ignition).

(*a*) Compression is normal.
(*b*) Carbureter in normal condition.
(*c*) Spark at the trembler.
(*d*) Battery in good order.
(*e*) Timer in good order.
(*f*) Primary wiring in good order.
(*g*) No ignition.

Unknown Quantities (involving the ignition).

(*a*) Secondary wiring short circuited?
(*b*) Secondary wiring open circuited?
(*c*) Spark plug short circuited?
(*d*) Spark gap excessive?
(*e*) Secondary coil open?
(*f*) Secondary coil short circuited?
(*g*) Ground contact not good?
(*h*) Trembler sluggish?
(*i*) Trembler screw loose?

CASE NO. 6—MOTOR WILL NOT OPERAT

Known Quantities (involving the battery).

(*a*) Compression is normal.
(*b*) Carbureter in normal state.
(*c*) Timer in good order.
(*d*) Wiring in good order.
(*e*) Ground contact of wiring good.
(*f*) No spark at the spark plug.
(*g*) No spark at the trembler.
(*h*) No spark at the timer.
(*i*) No spark across the battery (storage) termi
(*j*) Very old or much used dry battery.

Unknown Quantities (involving the battery).

(*a*) Battery dead?
(*b*) Storage battery sulphated?
(*c*) Storage battery fully discharged?
(*d*) Storage battery "mud" in cells?
(*e*) Storage battery short circuited?
(*f*) Storage battery active material fallen out?
(*g*) Storage battery very cold?
(*h*) Storage battery electrolyte evaporated?
(*i*) Storage battery electrolyte weak?
(*j*) Storage battery electrolyte strong?
(*k*) Storage battery jar broken?
(*l*) Dry cells dried out?
(*m*) Dry cells, zinc eaten away?
(*n*) Dry cells, chemical dissipated (transformed)?
(*o*) Dry cells, contact with terminals not good?
(*p*) Primary batteries, run down?
(*q*) Primary batteries, "polarized"?
(*r*) Primary batteries, elements eaten away?
(*s*) Primary batteries, solution neutralized?
(*t*) Primary batteries, solution evaporated?
(*u*) Primary batteries, jar broken?
(*v*) Primary batteries, inter-cell leakage?
(*w*) All batteries, local action?
(*x*) All batteries, impurities?
(*y*) Too small for the work?
(*z*) Not enough cells in series (or too many in

[*To be Continued.*]

Farms in Texas which formerly, in spite of their were practically worthless on account of their distan a market, are now being profitably cultivated by the an automobile.

A CHAPTER ON MAGNETO CONSTRUCTION

THOUGH the magneto has gradually won such an amount of confidence that the leading automobile manufacturers very generally rely on it alone to supply the indispensable spark, it is not without a slight regret that the automobilist has seen the suppression of the storage battery. It is not because the storage battery was frequently used for continuous running that it is regretted but because it allowed the engine to be started on compression and frequently saved laborious cranking in cold weather. European practice has been towards the abolition of the storage battery to such an extent that probably nine-tenths of the leading makers use magneto only.

Fig. 1.

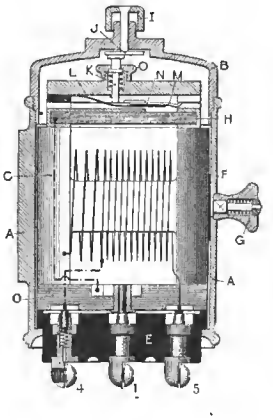

Fig. 2.

Fig. 1.—The Bosch Coil.—A, metal case containing coil; B, cover; G, commutator switch; I, starting switch; E, platinum plate-carrying contacts.

Fig. 2.—Sectional Drawing of the Bosch Coil.—A, metal case; B, cover; C, armature of the coil in form of double T; D, commutator plate attached to movable coil; E, fixed plate with contacts; G, commutator switch; H, condenser; I, starting switch; J, pin, with base of starting switch; K, platinum pin; L, spring with platinum contact; M, trembler (operating at moment of starting only); N, trembler spring; O, regulating screw; P, protective joint against dust and damp.

Thanks to the ingenuity of the Bosch experts, it is now possible to have the advantage of storage battery without the necessity for a complete double ignition system, the motor being started up from the seat—providing of course that a certain amount of fresh gas remains in the cylinders—by the simple operation of a switch causing a temporary working of the trembler. The new Bosch coil, as illustrated by Figs. 1 and 2, reproduced from *Omnia*, is contained in a cylindrical metal box of only about one-third the size of the usual trembler coil. It comprises the starting apparatus with trembler, a condenser, the coil proper, a commutator, allowing the passage at will from magneto to storage battery.

The metal case *A*, covered by the cap *B*, contains the soft iron core *C* in the form of a double *T* armature, this arrangement allowing of a coil of high efficiency while at the same time of small space and low weight. The winding, says *Omnia*, is identical with that of a Bosch high-tension magneto, the primary consisting of a small number of turns of heavy wire, and the secondary of a large number of turns of fine wire. The starting point of the primary winding is fixed to the core *C* and is thus electrically connected to the case *A*. The end of this winding is connected to the beginning of the secondary winding which forms its direct continuation. A wire connects the united ends of the two windings to one of the connections of the commutator placed in the lower part of the case. This connection should be joined up to the storage battery by a cable. The secondary winding also ends at one of the commutator connections which is linked up with the magneto distributor when ignition is made by storage battery.

The commutator is placed directly under the coil, so that its movable part *D* is attached to the armature core while its fixed part *E* constitutes the base of the box and receives the connections of the exterior wires on its lower face. The connections between the poles and the conducting parts of the rotary plate *E* are assured by four elastic contacts 2, 3, 4, 5, arranged in a circle, and a central contact *s* carrying a fixed pin.

The commutator is operated by means of a switch moving in an opening provided for it in the walls of the case. Starting from the intermediate position, which is zero, ignition would be

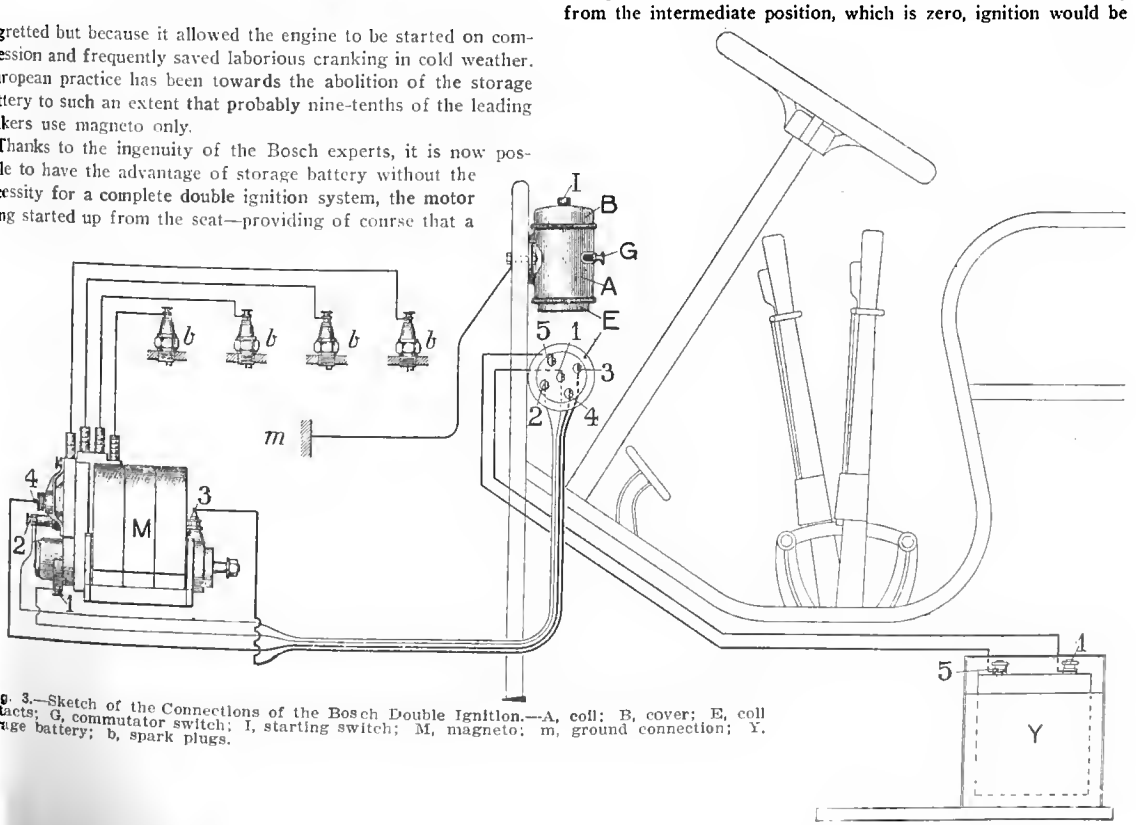

Fig. 3.—Sketch of the Connections of the Bosch Double Ignition.—A, coil; B, cover; E, coil contacts; G, commutator switch; I, starting switch; M, magneto; m, ground connection; Y, storage battery; b, spark plugs.

by magneto if the switch were pushed to the left; it would be by storage battery if it were moved to the right. There is a slot in the case for each of the three positions, the switch *G* being maintained there by means of a spring. To make a change of position it has first to be drawn outwards.

The condenser *H* is placed directly above the armature of the coil. One of its poles is given a ground connection, while the other is joined up to the central contact of the commutator. As one of the poles of the accumulator and the isolated contact of the magneto igniter are connected to the central contact the condenser is thus in parallel with the igniter.

All the parts just described come into operation when ignition is made continuously by storage battery; the apparatus working without the use of the trembler, the inherent defects of this organ are completely abolished and a reliable ignition is obtained. On the contrary, when the motor is started from the seat the trembler is momentarily put into operation to obtain the first sparks. This is necessary owing to the fact that the compression in the cylinders is never more than about half the maximum value, and the first spark is not certain to produce an e Once the motor has been started, however, the tremble out of operation.

At the center of the cover of the case is a starting s with a base *J*, against which a platinum pin *K* is pre means of a spring. On pressing down the switch *I* the driven down until it touches the platinum contact *L*. Th bler *M*, pushed upwards by the spring *N*, then comm vibrate.

The circuit is formed by the ground connection of the pin *K*, the spring *L*, the commutator, the storage batt primary winding, and is closed by the ground connectio coil. The current is broken when the trembler, drawn wards, strikes the spring *L*, for the contact between th and the pin is suppressed.

Four of the current models of Bosch magnetos, constru double ignition, can be modified by the changing of a f for this new device. Four other models can also be cha the new double ignition with very little trouble.

A NEW COMBINATION TIRE FOR HEAVY DUTY

IN the maintenance of heavy trucks tire cost is one of the most important items, and many attempts have been made to produce a tire which would utilize the cushioning action of rubber and take the wear on a harder and less expensive substance. The latest type of combination tire to be put on the market is the invention of E. S. Lea, of Trenton, N. J. The tire is applied to specially made wheels, which have the hub, spokes and rim all in one casting. Around the outer circumference are twelve deep recesses, each of which contains a cast steel shoe fitting in a thick rubber bed. The shoes nowhere come in contact with the rim, but have the cushioning action of the rubber on all sides. At the same time the entire wear is on the face of the shoes. The first wheels of this type, which were in use last winter in ice, mud and snow, had their shoes corrugated, but after the corrugations were entirely worn off it was found that the tread tion was as good as ever. They will therefore be left in the future. Each shoe is held on by two bolts wh through the rubber bed and the rim; these bolts have washers so as to allow a certain amount of play in eve

Cross-section Lea Wheel Showing Tire Bolt Attachment.

View of Lea Wheel and Sections of the Tire.

tion, giving the shoes perfect freedom of movement to t of any inequality in the road surface. Another comm point is that these tires can be replaced at about one-thir cost of ordinary solid rubber tires.

BOSTON ACQUIRED THE TAXICAB HABIT VERY QUICKL

BOSTON, Sept. 1.—Another new taximeter cab company has just begun business in Boston, making four which are in operation. The latest addition is the Taxi-Service Company, of which A. E. Morrison of the Morrison-Price Company is general manager. Its offices are in the Hotel Lenox, and the company has secured stands at the railroad stations and at some hotels, though as yet its equipment is not sufficient to take up these options. The Taxi-Service Company used American Locomotive cabs and it already has five in service, keeping them when not in use at a garage on Huntington avenue.

Still another taximeter cab service has been started v White steam cabs, said to be the first of the White Co output of this kind of vehicle. The cabs have the smal of White engine and landaulet bodies. They are operat the White garage on Newbury street. A third concern h business in a small way with an Elmore and an Atlas

The Taxi-Motor Cab Company, the first concern to a regular taximeter cab service in Boston with Thom is meeting with good success and its first allotment of five cabs is kept constantly busy.

LETTERS INTERESTING AND INSTRUCTIVE

THREE-POINT SUSPENSION AND GRADES.

Editor THE AUTOMOBILE:

[1,531.]—I note that several first-class cars use the three-point suspension and the unit power plant, but that this practice is not uniform. I should like to have you show how the motor can be suspended from four points of the frame without danger of having the alignment destroyed by road shocks and strains. I should also like your opinion of the unit power plant, and of the construction in which the change-gear is mounted on the rear axle.

On page 317 of your issue of August 27 you show a picture of an auto climbing what is claimed to be a 50 per cent. grade. If the grade shown is that steep, will you please explain how the percentege is reckoned? READER.

Cambridge, O.

The design of automobiles, like most other things, is a series of compromises. Three-point suspension and the unit power plant have many undeniable advantages, but they also have disadvantages which some designers appear to think more weighty. If one attempted to make a car in which every part was designed in the one and only correct way, the result would simply be a nightmare. The really good automobile is the one which, avoiding positive mistakes, embodies as many good features as will fit into a harmonious whole. The four-point suspension may easily be made rigid enough to withstand the strains due to road shocks.

In answer to the grade question, there is a pretty general impression that a 100 per cent. grade is straight up and down, 50 per cent. at an angle of 45 degrees from horizontal, and so on. In reality, the per cent. grade is simply the number of feet of rise to each hundred feet horizontally. Thus, a 100 per cent. grade is a rise of 100 feet in each 100 feet, 50 per cent. a rise of 50 feet in each 100. The per cent. grade, expressed decimally, is the tangent of the angle of elevation from the horizontal.

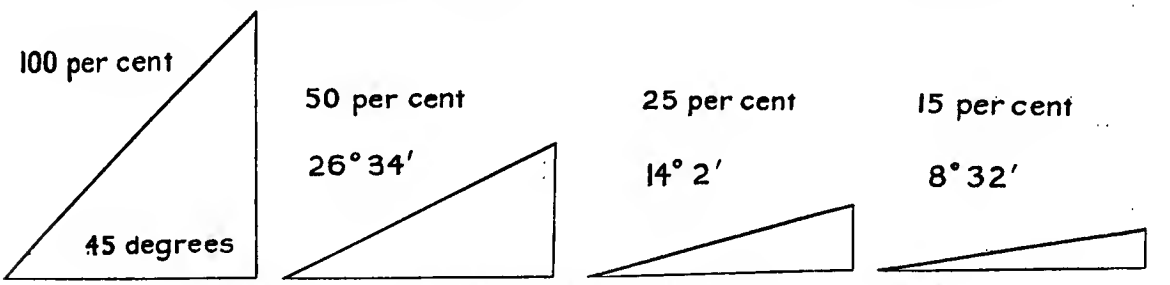

Diagram Illustrating the Various Percentages of Gradss and the Angles to Which They Correspond.

THE LOWEST SPEED OF AN AUTOMOBILE.

Editor THE AUTOMOBILE:

[1,532.]—We desire some authoritative information as to the lowest speed of an automobile. Can the average make of automobile, when necessary, run at a rate as low as ten miles an hour without injury to the machine? And would it in your opinion be under as good control at this speed as at a higher rate?

Suffolk, Va. J. M. BUTLER & SON.

Certainly an automobile can run at ten miles an hour without injury, and also be under just as good control. Any good machine ought to be able to run at five miles an hour indefinitely without the least trouble, and could run slower than that on the low gears, although if this were continued very long the engine would probably overheat. We do not see how the question ever arose, unless you were thinking of high-geared racing cars, which would probably overheat if run steadily at ten miles an hour. As to the ordinary touring car, however, there cannot be the least doubt of its ability to maintain this speed as long as desired, though there is no reason why it should ever be necessary to do so.

THE USE OF "DOPE" IN A GEAR SET.

Editor THE AUTOMOBILE:

[1,533.]—I have a light four-cylinder runabout and although it is new, only heen run a few months this season, I find that the planetary transmission makes what appears to be a great deal of unnecessary noise on the low speed, and more particularly on the reverse. I have been using oil in it as a lubricant and the local repairman informs me that a compound which he calls "dope," *i. e.*, a heavy mixture of oil and grease, would remedy the trouble. Not having any too much confidence in the repairman, I would like to have this from some higher authority before applying it. Will it do as recommended, and, what is more important, will it have any bad effect? W. T. LANSING.

Richmond, Va.

Given a large number of metal pinions running together and noise is inevitable; make these pinions small and revolve them at a high speed and the undesirable effect is increased. This is the case of the planetary gear-set on the small runabout of to-day. Its pinions are very small and they have to revolve at a very high speed, so that the elimination of the noise is impossible. Whether it is advisable to attempt to muffle it is another matter. Makers of such cars usually advise the use of a light oil in the gear-set on account of the small size of the pinions and their high turning speed, owing to the much greater resistance a heavy lubricant would impose on them. The use of "dope" will drown the noise to a very great extent, and as both the low speed and reverse gears are employed but little on such cars, it is a question whether it is better to put up with the noise during the comparatively short time in which its presence is unavoidable, or to fill the gear-case with a heavy lubricant, and put up with the loss in efficiency for the same reason, *i.e.*, that the working under such conditions only lasts but a short time. The use of "dope" for this purpose cannot do any harm that we can see and is not so apt to leak out of the case, as is the oil, so that where a driver perfers a slightly lesser efficient gear to an extremely noisy one, there appears to be no reason why he should not make use of such a lubricant.

BECAUSE COEFFICIENT OF FRICTION IS HIGHER.

Editor THE AUTOMOBILE:

[1,534.]—Can you tell me why it is necessary to use different metals in brakes? That is, why should the brake band, or shoe, have to be of a different metal than the drum upon which it acted? I have been puzzled more or lese over this, and as some makers go to considerable expense to provide a different metal, usually bronze, I have felt that there must be some good reason for it, but none of my friends have been able to enlighten me. BRAKES.

Pittsburg, Pa.

This is simply because when two pieces of the same kind of metal are rubbed together their coefficient of friction is not as high as when two similar metals are placed in contact and rubbed one over the other. In other words, the same kind of metal tends to slip upon itself more than a dissimilar piece would, such as bronze on cast iron or steel. For the same reason some makers do not rely upon different metals for this purpose, but

employ facings of special friction materials. Advantage is taken of this reduced coefficient of one metal upon itself in making pistons and cylinders of cast iron, as two pieces of cast iron will work better together than would any two pieces of dissimilar metal, that is, for this purpose, where the object is to reduce, and not to increase, the friction, as is the case where brakes are concerned.

WHAT TOLL FOR USE OF A PARKWAY?

Editor THE AUTOMOBILE:

[1,535.]—1. What rate per mile can the average automobilist afford to pay for the privilege of traveling over a comparatively straight and level macadamized road used only by automobiles, in preference to traveling over the ordinary country road?

2. Would a road built specially for automobilists along the route of an electric railway have a tendency to increase or decrease the amount of travel on the electric line? J. A. L.

Spokane, Wash.

It seems to us that you are putting the cart before the horse. A better way to go about the question would be to find the cost of constructing the road and figure the maintenance expense and the profits desired, and divide the total amount among the number of automobilists who could be expected to use it. As to how much the automobilist would be willing to pay rather than take to the public road, that depends so much on the individual pocketbook that it would be vain to attempt any generalizations.

We do not believe that the automobile road would affect the travel on the electric line in any way. People who own automobiles would probably use them in preference to the cars whether there was a special road or not. We will be pleased to print any other communications on this subject.

LEAKING OIL AND DECARBONIZERS.

Editor THE AUTOMOBILE:

[1,536.]—1. Our auto leaks considerable oil when standing in the garage and it has been our custom to save it. Is it possible to filter it so that it can be used again, and if so, how?

2. What possible harm can come from the use of the "decarbonizers" which one sees advertised so much? A SUBSCRIBER.

Attleboro, Mass.

The value of the oil as a lubricant depends on how long it has already been in use in the crankcase or gearcase. If you think it worth while, you could strain it through fine wire gauze. The best plan, however, would be to stop the leak, as there can be no excuse for the car's dripping oil at all. It may be that some of the drain cocks in the crankcase or gearcase are not completely closed; or else the leak may be through bearings which have become slightly worn or which are not provided with proper stuffing boxes. As the car probably loses as much oil on the road as it does in the garage, an hour's attention to the cause of the leak would prove to be good economy in the end.

The only way in which "decarbonizer" could damage the engine would be by corroding the cylinders or valves, through chemical action. We have had no personal experience with any of these compounds, but all the letters we have received concerning them seem very favorable.

EXCESSIVE CONSUMPTION OF FUEL.

Editor THE AUTOMOBILE:

[1,537.]—As a reader of "The Automobile" I wish to take advantage of the answer which I hope to receive in the next issue of this paper. I have a Pierce-Arrow car, 1906 model, 30 horsepower, in fine condition, everything perfect, and it consumes one gallon of gasoline to seven miles. When it was new I could go nine miles on a gallon. I know that my carbureter is perfect and everything else in the same condition. Can you kindly help me out with this matter and find out what other 1906 Pierce-Arrow cars do on one gallon of gasoline? BEN BOYD.

Bath Beach, N. Y.

Despite your assertion to the contrary, it looks as if there was something radically wrong with your carbureter. A car like yours should be able to cover at least fifteen miles to the gallon under ordinary conditions. Before taking ter up with the makers, however, there is another pc —a rather delicate one. Are you sure you get all the you pay for, and use all you get? A little investig those lines has cured more than one case of excess sumption, and that without recourse to the repair

INFORMATION WANTED ABOUT A SIX-C

Editor THE AUTOMOBILE:

[1,538.]—In one of the issues of THE AUTOMOBILE I six-cycle engine that was made and tried out in England to refer to this article and would like to have you let what number it was published in. I am quite certair shortly after the first of the year. R. S. PO

Minneapolis, Minn.

That six-cycle article certainly sounds familiar, and lieve that we published it sometime within the last least; but owing to the shortness of the article it was not in our files, and an exhaustive search has as yet failed it to light. We call the attention of our readers to th and hope some one of them will have a better memory t and will be able to help you out.

THE COAL-BURNING STEAMER ON THE R

Editor THE AUTOMOBILE:

[1,539.]—I enclose a photograph of my coal-burning st It works fine; the steel tires are a success and my drive a well without any differential. I burn either kerosene or

M. W. Hazelton's Coal-burning Steam Automobile

latter preferably, and can raise 100 pounds of steam f water in six minutes. This first car cost double what the made for in lots of a half-dozen at a time, as I got the pa six different States. I would like to correspond with parti ested in this car with a view of manufacturing it. The two-seated car, all of the best possible material, would \$700, and it will last longer than any \$2,000 car on the Tbe tires will last ten years. M. W. HAZE

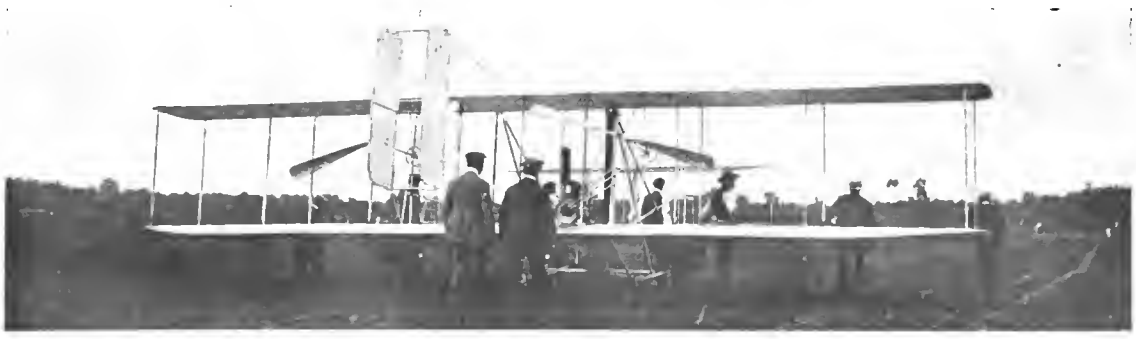
Oneonta, N. Y.

CONCERNING ONE MAKE OF CARBURET

Editor THE AUTOMOBILE:

[1,540.]—In reference to letter 1517, replying to the seco tion, beg to say that I have been using one of the Model carbureters on my Ford runabout all this year and w change it for any other. I first got it without the univer for the needle valve, but secured one later and now woul without it. I can always regulate the mixture accordin atmospheric conditions, and also according to the requi of the road, as for heavy pulling and hill climbing a richer mixture seems to help. I can drive at a high gear and have found it flexible for varying speeds. from my own experience, I feel sure that "Spark Gap" more than pleased with one, and I would certainly recomm ing it with the universal joint. W. S. HAG

Sharon Hill, Pa.



Wilbur Wright Making Preparations for One of His Many Successful Flights on the Old Fair Grounds at Le Mans, France.

WHAT THE BROTHERS WRIGHT ARE ACCOMPLISHING

WASHINGTON, D. C., Sept. 8.—Orville Wright, who is in charge of the Wright Brothers' aeroplane which was built under contract for the U. S. Army, arrived at the aeronautic testing grounds near here last week and at once began the work of tuning up his machine. He made his first flight Thursday evening. The aeroplane was launched by a falling weight after the now familiar Wright method, and rose slowly to a height of about twenty feet. Mr. Wright was noticeably nervous, and after being in the air for one minute and eleven seconds made a wrong movement with one of the levers, which brought the machine forcibly to the ground and broke one of the skids. Friday Mr. Wright tried again, after making the necessary repairs. This time he had the machine under perfect control and remained in the air four minutes and fifteen seconds, covering between two and two and one-half miles. He alighted gradually and without the least jar, and said afterwards that he came down merely because he did not want to attempt too much at once with a new machine.

On Labor Day Wright made one short flight of only 54 seconds, descending because of a defect in one of the steering levers. He has until September 28 to complete his official trials, and does not intend to take any unnecessary risks. He wishes to make several more preliminary flights to become better acquainted with the machine, so that the possibility of failure will be reduced to the minimum. In order not to crowd the time limit too closely, however, he will probably begin the official flights this week. It was learned to-day that Wright is preparing to go to Europe as soon as the Fort Myer tests are concluded. This is taken as confirmation of the report that a number of foreign governments are endeavoring to obtain Wright aeroplanes for military purposes.

How Auto Helped Aeronautically.

WASHINGTON, D. C., Sept. 1.—An automobile showed its innate superiority to Missouri mules as a tractor the other day when it was necessary to remove the Wright aeroplane from the Signal Corps balloon shed, at Fort Meyer, Va., to the balloon tent formerly occupied by the U. S. dirigible No. 1 on the aeronautic field. A 30-horsepower water-cooled Aerocar, driven by the owner, S. C. Crane, of Dayton, O., did the work in such a satisfactory manner that in spite of the rough spots of the road and a terrific grade, the aeroplane was delivered safely at its destination.

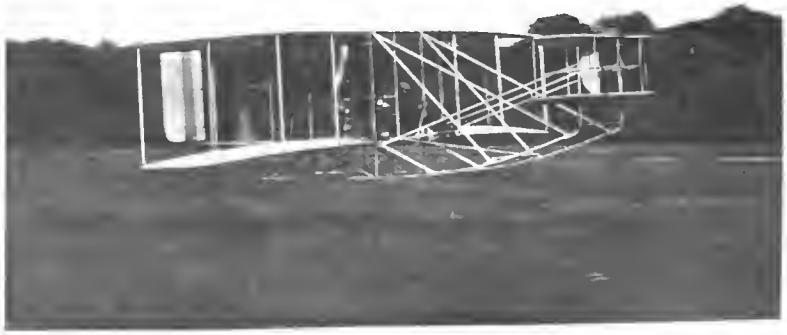
When the sky motor had been partially demounted in the afternoon it was placed upon a springless quartermaster's wagon with the length of the planes parallel with the length of the wagon. Then a pair of husky army mules were hitched to the end of the tongue. Mr. Crane, who is a friend of Mr. Wright, was near by with his car, and someone suggested that the automobile be used; but the mules started up the hill with their precious burden. The animals went at the job with jumps and starts, however, and Mr. Wright, usually calm and undisturbed, called excitedly to the muleteer to halt. When this had been accomplished it was but a few moments' work to hook on the Aerocar, so well adapted in name, at any rate, for the task.

With the low gears enmeshed the automobile started slowly without the slightest jerk taking up the slack, and towing the heavy army wagon with its strange freight up the rough road that led to the hill top. A squad of photographic sharpshooters ranged on the abutting hillside fired many a shot as the strange spectacle moved along.

Meeting a coach-and-four standing at the curb, Mr. Wright had the automobile stopped and got out to tell the grooms to move to some better place. He would not allow the machine to proceed until the owner of the four-in-hand had stated that the horses would not jump.

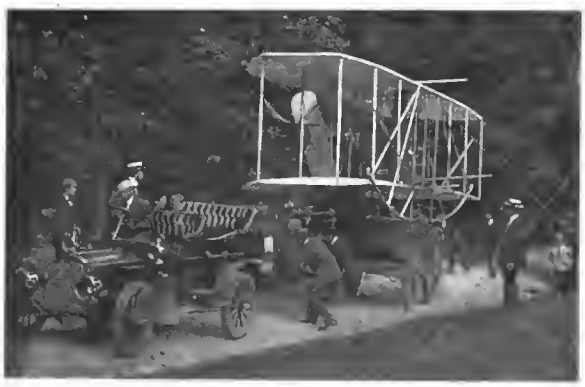
FLYING TO BE RENEWED AT ISSY.

PARIS, Sept. 3.—After turning the aeronauts out of the Issy-les-Moulineaux drill ground excepting for a paltry two hours at daybreak, the Minister of War has come to the decision that



Copyright, 1908, by Edwin Levick, New York.

Orville Wright's Aeroplane in Flight at Ft. Myer, Va.



Aerocar Hauling Wright Aeroplane to Shed.

it would be better to encourage what will be, in more senses than one, a rising industry, and has sent forth a declaration, after consultation with Chief of Police Lepine, that all sky pilots can come back to the suburban plain and experiment from sunrise to sunset. The only restriction is that there must be no aeronautical flights when the ground is being used by the military; as the troops are only on the ground about two hours every morning, the loss is not great.

The Issy ground will be rigorously closed to the public, a force of soldiers and police always being on guard when flights are being attempted. Though prevented from wandering on the ground the public will not, however, be denied a view of the flying machines, the high, broad walls of the fortifications being ideal gallery seats free to all. It is further announced that Colonel Picquard has other schemes in preparation for the encouragement of aeronautical experiments.

There is no doubt that this change of attitude has largely been brought about by the presence of Wilbur Wright in France. The American's demonstrations at Le Mans have shown that France is not alone in the struggle to obtain the secret of flight. Leading personalities in the aeronautical world have pointed out this danger to the authorities, and in order that they should not be left behind in the race for supremacy, official aid bas been given.

Only a few days ago there was no indication whatever that the authorities would consent to allow the Issy ground to be used again except under annoying restrictions, and in view of this several aeronauts had made preparations to move further afield. The Antoinette Company has secured the island of Tournedos, in the Seine, between Les Andelys and Rouen, and would remove there their own and many of the machines built by them; Henry Farman immediately on his return from New York had fixed upon a plain at Verneuil, 20 miles out for further experiments; and Leon Delagrange was still of a private ground.

Entries for the aeronautical section of the Paris anni are sufficiently large to give assurance of a very valuab of modern flying machines. Several machines of the and Delagrange type are promised, and Esnault-Pelt show both aeroplanes and his special type of light-weig

out with the usual gracefulness the machine refusec its helm, heeled over, then came to earth bruskly, bre of the skates. The broken part was repaired the same

Wilbur Wright declares that he will remain at Le M the contract with the French committee has been ful plished. He will then probably proceed to Berlin, to ma before the German army authorities. There is no trut clares, in the report that he is considering the crossi English Channel from Calais to Dover, such a journ present state of aeronautics being a foolhardy venture.

The special prize for a flight of not less than 82 feet will also be competed for at an early date, Wilbur W claring that he can get over the difficulty requiring the to start from the ground by its own power. He will ei on the catapault, descend until he skims the ground again for the height test, or start up direct from th without the use of any apparatus.

A dinner in honor of Wilbur Wright was given at du Dauphin, Le Mans, by M. and Madame Lazare Weiller those present being most of the French aeronauts ga Le Mans to view the flights, and Baron d'Etournelles de

NEXT GRAND PRIX NEAR CHATEAULAND.

PARIS, Sept. 3.—It is in the Anjou district, on the borderland of the famous chateau country, that the next Grand Prix will be held. No official decision has been arrived at, but Chairman René de Knyff, of the Racing Board, has expressed himself as convinced that this is the ideal course for 1909, and doubtless his colleagues will share his view at the next meeting of the board. The adoption of the course will be conditional on the raising of a subvention of $20,000, an amount that the Angieans believe they can get together.

The course, which is about 60 miles to the west of the town of Tours and in the valley of the Loire, was first proposed in 1906, its length then being about 70 miles. The town of Nantes, though some distance to the west of the proposed course, would profit by the race and decided to contribute one-third of the subvention demanded by the club. Since 1906, however, the Sporting Commission's opinion regarding the length of a course has changed, with the result that instead of 70 miles only 40 are required, a western portion has been left out and Nantes is no longer interested in the scheme. It thus devolves on Anjou and district to raise the necessary amount, which it will do by amounts contributed by the General Council, the Municipal Council and private individuals. Being in a district that annually attracts thousands of tourists, the benefit of the Grand Prix will be more widespread than is usual, with the result that all the towns along the Loire valley may be expected to contribute, and even Tours will not keep out of the movement. With such prospects of raising the subvention it is safe to declare that the 1909 Grand Prix be held at Anjou. The road surface is good throughout, the course being about as fast as at Dieppe.

ANOTHER FRENCH VOITURETTE RACE.

PARIS, Aug. 22.—There are prospects of good sport at the Voiturette race, to be held near Compiègne September 10 to 13, the present entries standing at thirteen, with the certainty of at least nine more being brought in before final closing. Those now on the lists comprise a Prod'homme, a Truffault, three Taine, three Lion-Peugeot, three Le Metais, and three Werner. The promised entries are full teams of Sizaire-Naudin, Aries, and Guillemin. Practically all the cars taking part in the Compiègne event ran in the voiturette Grand Prix at Dieppe, the drivers for the local event being in most cases the same as for the previous race. There are changes for the Werner team, the chief of which is now A. Autran, who was pilot with St. Chaffray on the De Dion New York-Paris car.

The task that the one lungers of 3.9 inches bore will have to accomplish is to race round a closed and somewhat hilly course for a total distance of rather more than 300 miles, all attention to the car after the start has been given being confined to driver and mechanic. Regulations differ slightly from those of the Voiturette Grand Prix in the bore limits allowed to two, three and four-cylinder engines, these having been carried to 80, 70 and 65 millimeters for each class. As the Grand Prix race showed, multiple cylinder engines with the previous bores were at a slight disadvantage. Two-cycle and the Gobron type of engines are admitted on the same footing as the four-cycle single piston motor.

CHATEAU THIERRY BECOMES HISTORY.

PARIS, Aug. 22.—After six consecutive years, Chateau Thierry has been abandoned as the scene of the annual autumnal hill climb. Last year a soldier on duty was killed by a motorcyclist in his endeavors to avoid an over-officious local fireman. A lawsuit followed, bad feeling sprung up between the municipality and the organizers of the competition, with the result that the district has been definitely abandoned. Though the value of the Chateau Thierry hill climb had gradually decreased as the automobile reached perfection, it still retained much of the importance which attached to one of the earliest automobile testing grounds in the neighborhood of Paris.

BRITISH TOURIST TROPHY RACE.

LONDON, Sept. 4.—The sole racing event promoted this year by the R. A. C. is to take place on September 24, the Isle of Man being, as usual, the scene of operations. The 38-mile course originally used for the Gordon Bennett eliminating trials has been reverted to in place of the shorter lap used in the previous T. T. races. Instead of the fuel limitation which has been the feature of these events, the cylinder bore is restricted this year, the maximum for a four-cylinder engine being four inches. Forty entries have been received, of which 22 are British and 18 foreign, no American car figuring in the latter section.

Dealing with the cars themselves, some extraordinary statements have been published, both with respect to the power of the engines and the speed attained in practice. The Humber Co. credibly state that their engine has developed over 70 B.H.P. on test. This engine has stroke of 6 inches compared with 4 1-2-inch stroke of the Calthorpe and the 6 1-2-inch of the Arrol Johnston.

In an event at the last Brooklands meeting, the Hutton car, which is entered for the coming race, was certified to average 83 miles an hour, and this fact lends some credence to the belief that the race will be extremely fast. Practicing has not yet commenced, for, owing to the crowded state of the island at present, competitors are not allowed to land their cars till September 3, and then they must not be on the road after 9 A. M.

The whole of the course has been treated with a dust-laying preparation to lessen risk of accident.

BRITISH ARMY TO HAVE TRACTOR EVENT.

LONDON, Aug. 22.—Being in the market for automobile tractors capable of handling eight-ton loads, the British Army authorities announce a competition for February next. The vehicle winning the competition will be bought at the conclusion of the trial at the price stated on engagement blank, providing the experts consider it suitable for army work. The authorities also promise provisionally to buy other vehicles if satisfactory.

Full liberty is given in the class of engine and fuel used, but price of the tractor must not exceed $5,000. Economy in fuel consumption is essential, and liquid having a flash point of less than 75 degrees Fahr. will be barred. Kerosene may be used for starting, providing the engine can be started from cold in less than twenty minutes. Points on which the awards will be made are, among others, distance and average speed at which eight-ton loads can be hauled without replenishments, cost and efficiency, hill climbing power and ability to work away from highways, accessibility, ease of repair, absence of noise, vibration, etc.

The test will extend over fourteen days, during which time the vehicles will have to run over level and hilly roads, submit to brake tests and be dismounted for examination.

GRAND PRIX CARS AT BROOKLANDS.

LONDON, Aug. 27.—Grand Prix racers will have an opportunity of showing their ability on the track in a race that has been specially designed for them at Brooklands, Saturday, October 3. The general conditions as regards engine sizes, weights, replenishments, tire changes and colors are the same as those for the French 1908 Grand Prix. The distance will be about 100 kilometers. Eight cars of non-British origin must be entered, or the executive committee will have the right to declare the race void. The sporting commission of the French club has been invited to appoint three stewards to adjudicate on the race in conjunction with the British representatives, and the automobile club of each country having made an entry is invited to appoint a representative. Entries close on September 25, the fee being $200 per car, of which sum $160 will be returned if the car starts.

Nazzaro, the famous Italian racing driver, winner of last year's Grand Prix, has announced that he will give up racing for 1909. In September he is to lead to the altar a charming young lady of Turin.

Seven Bluecoats in a Gearless Great Six Patrol Car.

LOS ANGELES HAS AUTOMOBILE PATROL.

Los Angeles, Cal., Sept. 5.—The police department of this city recently acquired a Gearless "Great Six" for use as a special patrol car. It is fitted with searchlight, fire extinguisher, stretcher for injured persons and other special appliances for police work. The photograph shows the car with full load of bluecoats in front of one of the police sub-stations. It has been in use for over eight months now and has made such a good impression on the authorities that they have placed with the Gearless Motor Car Company an order for a special 14-passenger patrol car. This will be fitted with a solid paneled enclosed body, and will be the largest automobile patrol in use in the United States.

AUTO TRUCKS WITH FLANGED WHEELS.

In the illustration shown below is one of the new 2,000-pound trucks sold by the H. H. Franklin Mfg. Co., of Syracuse, N. Y., to the Thacker Coal and Coke Company, through the Franklin Company's Philadelphia agents, the Quaker City Automobile Company. This truck has been fitted with steel-flanged wheels, and will be run upon the railroad tracks throughout the Pennsylvania mines and shipping yards of the Thacker Company for carrying supplies and general utility purposes.

This use of the automobile truck in the transportation of coal mine supplies is another step in advance, and proves the great variety of uses to which trucks can be put. It can be made to effectually supersede the time-honored hand car, and will undoubtedly supplant it in the near future for general railroad purposes.

Franklin 2,000-lb. Truck for Pennsylvania Mine Work.

NEW BUILDINGS FOR PEERLESS

Cleveland, Sept. 2.—Within the next two years, within a month or two, the Peerless Motor Car Co., o will spend in the neighborhood of $750,000 for new adding them to the present group. The new structu erected just north of the present plant.

The first of the new structures will be built in the n and will be a repair shop 53x130 feet long. It wi stories high, of reinforced concrete and steel. The cos the neighborhood of $26,000. The rest of the buildi new arrangement will cost upward of $350,000 with that will bring the total well up to $750,000. This v a new erecting and assembling building with machir front of which structures will be the administration offices, respectively. When completed, the front will attractive design.

The present plant, consisting of machine shops, er assembling shops, foundry and other departments, is high. The extensions will all be three stories. Th it now stands was developed in about three years. A street will separate the present and new groups. Th tion as planned will take about two years altogether

Shearing Sheep with a Cadillac in New Zeala

HOW RAMBLER PARTS ARE SUPPL

Kenosha, Wis., Aug. 31.—All automobile factories nize the importance of being able to fill orders for r with quickness and dispatch. Thomas B. Jeffery and of this city, the makers of the Rambler, claim to ha duplicates of every part of every Rambler manufac 1902, and further to be able to ship replacements or day the order reaches the factory. This promptness the thorough organization of the sundry departmen parts supplied on order are inspected by two men accuracy, and again, in the shipping room, the ord stamped and double checked to avoid mixing orders The sundry department contains 1,500 bins of variou arranged in sections eight feet in height. In this kept only such parts as are in most frequent dema are stored in a reserve stock room. In addition th annex, motor stock, transmission stock and axle stock

The fact that there are fourteen thousand Ramb use, many of them now in their fifth or sixth year makes this department very valuable to owners, whi that all Rambler parts are made in the Rambler fact the company to supply them very cheaply. Although t may not be needed during the first or second season tion, the company sees the wisdom of manufacturing ing on hand extra parts of all models so that in yea owners may procure them without delay and at a reas

PLANS FOR THE "AMERICAN" TRUCK.

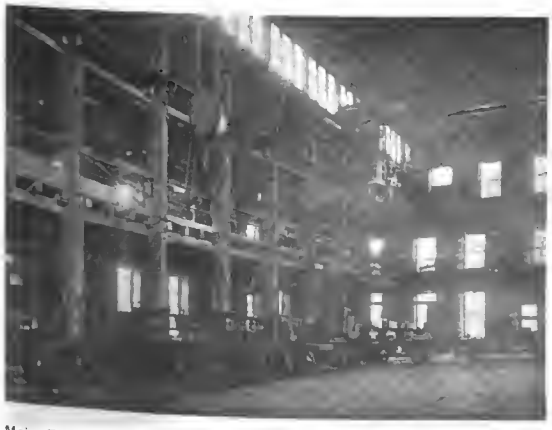
LOCKPORT, N. Y., Sept. 8.—The recent announcement that E. B. Olmsted, one of the pioneers in the manufacture and sale of commercial automobiles, had taken over the management and control of the American Motor Truck Company, of this city, is an assurance that the "American" truck will be frequently heard from next season. This company has been manufacturing commercial vehicles exclusively since 1904. Two years ago a large building formerly occupied by the Holley Mfg. Co., was secured and equipped with modern machinery and appliances, and all parts of the truck are now made in this plant. Plans are now under consideration for extensions to permit of a larger output. The main erecting room occupies the entire ground floor of the main building, which has an area of nearly 25,000 square feet. Most of the machine work is done in the galleries. The testing room and the body making and wood working departments have an area of about 4,000 square feet each. The plant is equipped with traveling cranes for facility in handling heavy parts, an air compressor for riveting, electric drills, and in fact every modern appliances for performing the best work in the shortest time. The entire machinery of the plant is driven by electricity, the current being generated at Niagara Falls, twenty miles distant.

E. B. Olmsted

As to the plans of the company for 1909, Mr. Olmsted states that in addition to its three and five-ton gasoline trucks and passenger stages, it will have a line of trucks and delivery wagons from one ton upward, and passenger vehicles from ten passengers up, both open and closed types.

El Paso, Tex.—Probably the first public delivery service by motorcycle is that enjoyed by this city. An interprising motorcycle agent originated the idea, and now has a complete system for either quick delivery or messenger service. The rates are very reasonable, and it is obvious that in the way of speed the motorcycle has a very perceptible advantage over the usual messenger boy with his cigarette and "Diamond Dick."

Tampa, Fla.—The automobile line between Bartow and Mulberry, the formation of which was announced recently, has proved such a success that the management has been forced to put on another car. In addition a trip is made to Tampa on Sundays.



Main Erecting Room, American Motor Truck Co., Lockport, N. Y.

Rapid Cars Loading Passengers at Station for Mudlavia.

COMMERCIAL RAPIDS CHEAPER THAN LIVERY.

ATTICA, IND., Sept. 8.—Five miles from the railroad station at Attica is "Mudlavia," a resort very popular with people from Chicago and St. Louis because of its mud baths. The hotel can accommodate about two hundred guests comfortably, and represents a large investment. Formerly a livery service was maintained between Attica and the Mudlavia Hotel, but early this year it was replaced by an automobile service. Three cars, furnished by the Rapid Motor Vehicle Company, of Pontiac, Mich., are used, two for passengers, twelve-seated, and the other for baggage. Now, upon arriving at the railroad station at Attica, guests are taken care of by uniformed attendants, placed in the automobiles and taken for a five-mile spin, through a beautiful country and over some of the best roads in the State, reaching the hotel in about half an hour. From four to eight trips are made a day with each car, meeting all trains and eliminating any waits for conveyances. The service is in every way superior to that of the horse livery, and is maintained at a saving of about $250 a month. The Kramer-Allen Motor Company, of Attica, which cares for the cars, has made out the following statement of the expense of the service during the month of June:

Items—	'Bus No. 1.	'Bus No. 2	Truck.
Driver's salary	$40.00	$40.00	$36.00
Cost of oil	2.70	4.50	1.57
Cost of gasoline	10.78	16.06	12.10
Miscellaneous	39.60	28.93	59.85
Total cost	93.08	89.49	109.52
Gallons of oil used	6	10	3½
Gallons of gasoline used	98	146	110
Number of passengers, regular	240	487	4
Number of passengers, D. H.	32	51	17
Number of trunks	.....	.....	206
Number of days operated	18	27	29
Cost per day	$5.17	$3.31	$3.77
Number of miles operated	506	990	660
Cost per mile	$1.182	$ .093	$1.65

These results are the more remarkable when it is considered that the cars were run, not over paved streets, but over country roads which, although good of their kind, were far from ideal.

ILLUSTRATING THE GROWTH OF AUTOING.

Washington, D. C.—The old horse-drawn sprinkling carts will soon disappear from the streets of this city, and will be replaced by the latest type of automobile sprinklers. Superintendent McFarland, of the local water department, is responsible for the change. He is a firm believer in modern methods and succeeded in converting the commissioners to his view of the question.

Columbus, Ohio.—An automobile line has been started by Columbus promoters between Marysville and Magnetic Springs, connecting with the interurban line to Marion, Richwood and Columbus. The car carries 32 passengers and makes two trips daily.

Greensburg, Ind.—Greensburg and Clarksburg are now connected by a new automobile line, and another will shortly be established between Greensburg, Osgood, Napoleon and Versailles.

The "Blue Bird" Captures a Deer en Route.

600 MILES THROUGH THE MOJAVE DESERT.

The same Chalmers-Detroit Forty *Bluebird* which won the Rocky Mountain Cup race at Denver last Memorial Day has just completed a wonderful trip of 600 miles through the Mojave Desert of Southern California.

The tourists encountered quicksand, rivers, mudholes and a cloudburst, in addition to the ordinary desert obstacles of deep sand, cacti, hills and gullies. The car averaged 30 miles an hour, which is very high for that kind of country.

The party consisted of Lawrence Knapp, an expert driver, and Joe Desmond, a wealthy business man of Los Angeles. Their objective point was Owens River, from which a huge aqueduct, 250 miles long, is being built to supply Los Angeles with water.

In fording a pond apparently shallow, 85 miles out of Los Angeles, the car was nearly submerged at a place where the road had been washed away. The magneto was soaked and had to be dried out in the hot sun. No other trouble.

In Red Rock Canyon the party encountered quicksand. The car sank until the runningboards rested flat on the surface of the sand. Only by the hardest kind of work was it jacked up and pulled out. The following day heavy rain and mud were encountered. Two days were spent visiting various camps and then the return journey was made. Driver Knapp reported that except for taking the magneto apart to dry, not a single adjustment was made on the entire trip.

It will specially interest American tourists to learn that the Dowager Queen of Spain has been the first motorist to legitimately cross the great St. Bernard in an auto. The Italian side of the road is open, the Swiss, on the other hand, closed, and as Her Majesty desired to pass she telegraphed to the Swiss government for permission, which was at once granted.

Emerging from San Francisquito Canyon.

Lighthouse That Warns the Mariner at Montauk Point.

The Lonely Road Across the Meadows to the Light.

Where the Headland of Montauk Point Meets the Sea.

TO MONTAUK POINT AND RETURN.

By PATHFINDER.

How many tourists, residing in Greater New York, have explored Long Island from end to end? Fewer, I will wager, than have visited the White Mountains, the Maine woods or the Adirondack region. The reason is not far to seek—we New Yorkers have a habit, when we wish to go sightseeing, of journeying far afield and neglecting the wonderful things which are at our very doors. For my part, I must confess that, until last week, I had never been further east on Long Island than Southampton, and I certainly would not have thought of taking such a trip as that which I am about to describe had not the promoters of the "Mechanical Efficiency Contest," to be held by the New York Automobile Trade Association, asked me to lay out a route to Montauk Point and return.

Leaving Columbus Circle (which is to be the starting point of the contest), we journeyed in our 30-horsepower White steamer to the country house of the Crescent Athletic Club, on the Shore road at Bay Ridge. This is the point on Long Island which is farthest west and it has very appropriately been selected as the place where the contestants will begin to travel on a schedule. Continuing to Bensonhurst, we turned from Twenty-second avenue into Kings highway, which is one of the oldest thoroughfares on Long Island. It winds in and out to Gravesend, then over towards Sheepshead Bay and through the old Dutch settlement of Flatlands. There are a number of old houses on this road which date back to Colonial times. Then we get back to the activities of to-day as we reach the Eastern Parkway and travel by the usual route to the great Merrick Road, which we follow through Lynbrook, Rockville Center, Freeport, Massapequa and Amityville to Babylon. Then, continuing straight along this same road, now called the Southern boulevard, we pass the magnificent estates which line the shore of Great South Bay—through Bay Shore, Islip, Oakdale, Bayport and Blue Point to Patchogue. Now we have reached the great Long Island "Summer boarder district," and we pass quickly through Bellport, Brookhaven and the Moriches to Quogue. Then we come to Good Ground and the famous Shinnecock Hills and finally to Southampton, where again we see many magnificent country estates. Then, after passing through a few more towns, the names of which end in -hampton, we reach Amagansett. Up to this point the greater part of the going has been over fine macadam roads, with hardly a suggestion of a grade. We have also noted with pleasure that the custom of oiling the roads is wellnigh universal in this section. But east of Amagansett we get something very different—not only a different style of road but different vegetation, different topography and different scenery from anything we have ever seen before on our travels.

The twenty miles of country from Amagansett to Montauk Point is made up of sand dunes. For miles at a time one does not see any vegetation except a sort of rank, stubby grass. There is no road in the usual sense of the term. The wagons, traveling in the same ruts, have worn a well-defined path and no one need have fear of losing the way. In some places the going is rather heavy and in spots it might even be called swampy, but certainly there is no obstacle which can bar the progress of a good touring car. It is about time to put an end to the myth that "the road beyond Amagansett is practically impassable." As for our White steamer, it plows through the sand and up the short grades with no more apparent effort than when on a macadam road.

There can be no question but that the eastern end of the island is very desolate. Not a habitation is seen and no wagons are met with along the route. Occasionally the road, or to speak more accurately, the trail, approaches close to the edge of the crumbling sand cliffs and we see and hear the waves breaking upon the shore, 40 to 60 feet below our feet. Let nothing more be said about "the waves washing over the road." Possibly a tidal wave would do so, but not the kind that ordinarily corrugate the surface of the broad Atlantic.

The first building we see after leaving Amagansett is the U. S.

life-saving station, five miles from the town. We proceed an equal distance and then pass another life-saving station. Evidently this is a dangerous section of the coast for the mariner. Now our road bears away from the shore and we skirt the edges of a fresh water pond. Then Montauk Inn comes into view and, after a stiff quarter-mile climb, we alight at this delightful hostelry.

From this vantage point a splendid view of the surrounding country is presented. In the very desolateness of it all, there is something akin to grandeur. But those sandy hills were not always bare. Ten years ago, at the time of the Spanish War, somebody blundered and ordered some 20,000 soldiers to pitch their tents here—in a delightfully healthy climate, to be sure, but there was no barrier between these valiant men and starvation, except a single-track railroad. Finally, as we all know, everything was straightened out, but not until a third or more of the men were in the hospital tents. The dwellers in the little settlement on the shores of Fort Pond bay, a half mile from the inn, will tell you all about the scenes of a decade ago—but the subject is not a pleasant one to pursue further. Besides, no one is supposed to discuss any phases of war, except its "glories."

The settlement of Montauk, where the inn is located, is at the end of the railroad, but not at the end of the island. We have a journey of 6 1-2 miles across the dunes before we reach Montauk Point, on the very extremity of which is the lighthouse. Here we are greeted by the keeper, Capt. Scott, who has been "on the job" for 23 years. He looks over our machine critically and remarks, "They certainly make fine automobiles nowadays. I s'pose people will soon be traveling here in airships." "May Heaven help them if they do not make a landing here," we reply, gazing out toward Europe.

Retracing Our Steps to the Metropolis.

From Montauk Point we retraced our way across the dunes to Amagansett and then along the Southern boulevard to Good Ground. Here we turned off to the north and made our way through Riverhead to Wading River, where the sound comes into view. The topography of the north shore of Long Island is so different from that of the south shore that one can hardly believe that only a scant six to twelve miles separates the two coastlines. While the south shore is as flat as the prairies, the north shore has all the characteristics of a mountainous region, which means that the road leads constantly up and down hill and some of the grades, it might be said, require a wide-open throttle, even on our car.

On we go through Port Jefferson, Setauket, Stony Brook, and Smithtown. Then we pass through the grounds of the great State institutions at Kings Park where maniacs are confined —all except speed-maniacs, most of whom are still at large.

Then we go through Northport, Huntington and Oyster Bay. Just as we are leaving the latter town, we catch a glimpse of President Roosevelt and Mrs. Roosevelt as they whirl by us in one of the government White steamers. We toot our horn uproariously and the President acknowledges this "automobile salute" by tipping his hat. Then after passing through Glen Cove and Sea Cliff we come to Roslyn and Manhasset, of Vanderbilt race fame. Keeping straight ahead on Broadway, we continue into Flushing where, in the two-day contest of next week, the contesting cars will check in for the last time and will then proceed on whatever schedule they may desire to the finishing point at Columbus Circle. It is a safe prediction that all who take part in the run, even the veterans of the A. A. A. tours, will describe the 300-mile journey as the most interesting and picturesque two-day trip of their experience.

Prince Henry of Prussia is very content with the proposal to wind up next year's race in South Germany and to hold the speed trial on the flat in Forstenried Park, near Munich. It is quite likely that Austrian territory will be taken in as well. This race is now the principal event on the German automobile calendar, and is fast assuming international importance.

Tourists Will Pass "Idle Hour."—W. K. Vanderb

Where the Road Circles Round Fort Pond at

WILKES-BARRE IS AN ACTIVE AUTOMOBILING CENTER

By F. S. SLY, Traveling Correspondent of The Automobile.

WILKES-BARRE, Pa., Aug. 31.—This city may easily be put down as one of Pennsylvania's chief centers of autoing, for, considering its size and situation, it is really ahead of Philadelphia on the east, or Pittsburg on the west, where live interest in automobiling is concerned. Much of this is naturally due to the Wilkes-Barre Automobile Club, of which George F. Lee is president, Peter A. Meixell, vice-president, and Dr. E. C. Wagner, secretary and treasurer, as there are few more progressive organizations of its kind to be found anywhere in the country. It now has 150 members and is doing a great deal of good work.

The plant of the Matheson Motor Car Company being located in this city also serves to keep the automobile and its interests constantly before the public, as the numerous testing cars from the factory are constantly on the go and always in evidence.

But interest is not confined entirely to the pleasure car, as on June 29 last the Wilkes-Barre Motor Transit Company started a stage line making a round trip of 3.1 miles in the city, the distance being covered in 30 minutes. The equipment consists of three Manhattan, 50-horsepower chassis, built by the Mack Brothers Company, Allentown, Pa. They have a four-cylinder vertical motor, equipped with a Breeze carbureter and a Splitdorf magneto, and fitted with a special type of 'bus body in which the entrance is at the front, so that the passenger has to deposit his fare in a special receptacle in close view of the driver. Two of the cars are kept on a 15-minute service, while the third is maintained in reserve for emergency purposes, as well to permit of an increase of the service in rush hours, such as on Saturday night. On Sundays only church trips are made. The fare is five cents each way, and the record for a single trip is 34 passengers, while the average day's travel ranges from 200 to 375 passengers per car. The cars seat 16 passengers comfortably. It was originally intended to employ electric lights, using storage batteries as the source of current, but this did not prove entirely satisfactory.

Generally speaking, the roads in this part of the State are bad; without making exceptions, it would be difficult to truthfully characterize them otherwise. At present, the best roads, and, likewise, the favorite drives of autoists in this section, are to Harvey's Lake, over Pocono Mountain, the middle road to Aspen, and to Newport Mountain. There is now under construction a State road running from Nanticoke to Wilkes-Barre, and this will serve to increase the available mileage open to autoists in this section by a considerable stretch of fine highway.

There are now four good garages here and quite a number of well-known cars are represented. The Wyoming Valley Motor Car Company handles the Locomobile and Buick; Ford is represented by an exclusive agency, also maintaining a garage. Robert Johnson represents the Rambler, Mitchell, and Knox; and William Lee has the Oldsmobile, each one of these concerns maintaining an up-to-date garage.

Anthracite Districts Have Few Good Roads.

SCRANTON, Pa., Aug. 31.—Roads in this section of Pennsylvania are very poor, with the exception of a single toll road on which 35 cents is charged, and the private roads of the Scranton Gas and Water Company, leading from the toll road to the various reservoirs of the company back in the mountains. These are remarkably well-kept stretches of macadam and constitute the favorite drives hereabouts, being crowded on Sunday afternoons.

Interest in automobiling is active, the Scranton Automobile Association, which was only organized last spring, now having 125 members on its roll out of a possible 350, which represents the approximate number of cars in use in the city and vicinity. The officers are: President, H. B. Ware; Vice-President, George B. Jermyn; Secretary and Treasurer, Hugh B. Andrews. The organization is a live one and keeps its existence constantly in the public eye by the use of a small club flag which is displayed on the cars of all the members. The number of these that are always in evidence round town makes the membership of the club apparently much greater than it is.

Quite a number of well-known American cars are represented here, and while dealers report that business has been fair all along, it is the opinion of the majority that it does not average up to what it was at the corresponding period of last year. The Thomas is represented by the A. R. Gould Wagon Company; Conrad Brothers handle the Ford, Premier, Reo, and Aerocar; and the Standard Motor Car Company represents the Pierce-Arrow and the Autocar, both the last-named concerns maintaining garages. A third is run by the Scranton Garage and Motor Company, which also handles the Franklin and the Buick.

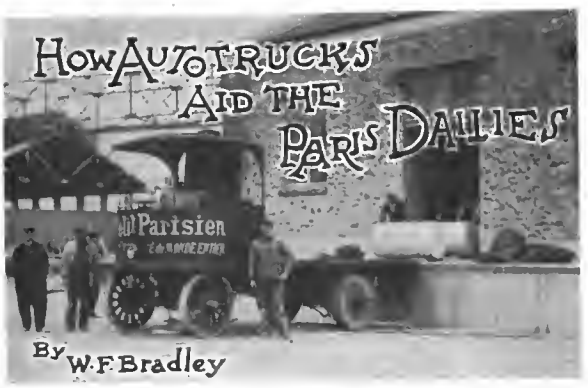
QUESTION OF WEIGHT IN THE BUILDING OF AUTOMOBILES

By CHARLES CLIFTON, George N. Pierce Company, Buffalo, N. Y.

THE Glidden and Hower runs, which have now gone into history, certainly justified the weight which we put into our chassis. We had no structural trouble of any kind. Our cars certainly ran every other car to the breaking point, covered more miles than any other, and were in shape to repeat the performance. Almost every car competing with us in this country has more or less rear axle trouble. We have practically none. Almost every car in the market has spring trouble, while we have practically none. Now, these results are not accomplished by light weight construction, or by cheap construction, and all these results can only be obtained by putting in weight intelligently.

If you will look over modern rolling stock in other lines, and other mechanical devices, calculated for long and strenuous use, you will observe practically as follows: All railroad equipment has been very much increased in weight. The pressed steel car, which is the most modern of its sort, is heavier and more expensive than the old wooden car, but it is more economical because of its longer life and less liability to accident. Take the experience of the Pullman Company with their cars. They have developed them along the same line that we have; namely, by watching them in the repair shop, and as the result of accidents, and the result is that the public is now satisfied to pay what the Pullman Company asks, if for no other reason than because the liability to personal injury in the Pullman car is practically nil. Looking also to the locomotive practice of to-day, where no effort is made to get light weight, but that service is the main consideration. This is the same in the development of electrical machinery. The cheap thing has no place in that line. These machines are built substantially for long and satisfactory use, all of which means weight, careful workmanship and the very best of material.

If you will look over the history of the motor car business for the past ten years, I think one fact will stand out preeminent; namely, that in all competition, at all times, and under all conditions, there is one great foreign concern that has always held its own where others have had meteoric periods of brilliancy. Tbis one concern has gone on in its quiet way building a heavy car, but always holding its own from year to year, and increasing its business, until it is one of the largest if not the largest producer in the world. I refer by this to the Panhard. This car, with equal power, is a heavier car than ours, but no one can gainsay its position in the trade.



Loading Up a Truck at the Door of the Paper Mill.

PARIS, Sept. 3.—Supplying an important daily newspaper with reels of white paper is an operation requiring as much regularity and as much dispatch as the supplying of the same paper, printed and folded, to newsdealer and reader. The capacity of modern rotary presses is enormous, so large, indeed, that the manager of many a city daily is sore pressed for space in which to store the huge rolls which later will be impressed with the news of the day. Floor space is generally limited, for rents are high in the neighborhoods in which daily newspaper offices are obliged to locate; the paper mill is usually miles away, for economy demands that trees shall be transformed into newspaper near the source of supply where water is plentiful, and where rents are low. Hence the necessity for frequent renewals of the long reels of white paper which furnish news for the millions under the touch of the rotary press.

In Paris the difficulty of supplying the printing presses with stocks of white paper is keener than in most capitals, not because the journals are larger, but because they are housed in cramped quarters, offering little room for reserve supplies. Circulations have increased, but the walls of the printing office have remained as before, with the result that now a daily supply is needed from the paper mill to keep the presses running. There is further complication from the fact that the printing offices are all around the most crowded portion of the main boulevards and are reached with difficulty by heavy horse teams. In bad weather, under the old system, the foreman printer was often on tenter-hooks regarding the next supply of paper; it only needed a frozen pavement or a lame horse to seriously jeopardize the success of the next edition.

The outcome was the introduction of the automobile performing regular daily services between the mills and the newspaper offices, and the almost entire abolition of the horse. At the present time all the more important dailies, such as the *Petit Parisien, Le Journal, Le Matin* and *Petit Journal* receive their supplies of blank paper daily and exclusively by automobile. As the papers mentioned, together with their auxiliaries, comprise all the most important dailies, having combined circulations running into many millions, the morning delivery van has become as standard as the milkman's cart on the main boulevards.

Nine-tenths of the paper for the Parisian dailies is supplied from mills at Nanterre, ten miles out of town. By horse traction this meant a journey of three hours, the road being a varied one of good granite paving, bad ditto, moderate macadam, a few hills, and crowded wood-paved boulevards. Taking six rolls as the maximum load for a two-horse team, this required eight different journeys for the delivery of the daily supply of any of the more important papers.

By automobile eleven to thirteen rolls are carried at once, the total weight being from 5 to 6 tons, the distance is covered in one hour and a half, and the return is made within the hour. Taking the *Petit Parisien* as one of the most representative of the Parisian dailies, the first load leaves the mills at 5 a. m., loading having taken place the previous day, and the rolls are deposited at the door of the press room 90 m Thirty minutes after the departure of the first vehi is ready to start, the service being continuous all d vals of half an hour. For the return the autom are if not empty, at least light, for all that has to l are the returns and waste paper.

Although some of the larger papers own and m own fleets of trucks, a co-operative system is ado others, while many more are supplied by the man a fixed inclusive rental, with a number of journeys

On an average the inclusive cost of transport this system works out at rather less than $9 pe vehicle making a maximum of three journeys per da ing a total of 15 to 18 tons of paper, exclusive returned to the factory. All the vehicles in use steamers, with their engine forward, and driven by to the rear wheels. Rubber tires are not used, all front and rear, being shod with steel bands.

The cost of a vehicle of this type, complete w for carrying rolls of paper, is about $3,000. As th of such a truck is ten years, the average amount off for depreciation is $300; interest on capital inv rate of 5 per cent, is responsible on an average year; various insurances, automobile and drivers' $100 per annum; maintenance and repairs work ou of $350 per annum. This makes a total of $83c which at the rate of 250 working days per year cost of $3.35 per vehicle per day. Running expense

Driver	$1
Coke, 4 cwt. per day	2
Oil, grease, firing, waste	0
Water	0
	$5
Maintenance, interest, etc.	3
Total per day	$8

Apart from the economic value of automobil traction for a service of this nature, there is public value by lessened congestion on the city's the first portion of the journey a speed of ten r can be maintained; on the hills this is cut down to hour, and later in the crowded portions of the cit tain hours, has to be reduced to a crawl of three Under all conditions, however, the five and six-t capable of keeping pace with the stream of ho the boulevards, the disturbance which was forme the two-horse teams—and is still caused by the maintaining horse service—being conspicuously ab automobile service. In cities such as Paris and L street traffic is particularly dense, heavy horse coming more and more of an obstruction. So the difference between the two systems of hau closing of more important highways to the heavie horse vehicles is already proposed.

Unloading Paper at the Press of a Paris

PROBLEM UNSOLVED: IDEAL ROAD FOR HEAVY MOTOR TRAFFIC

PARIS, Sept. 4.—Most important of the questions to be discussed at the international road conference which the French Government has called for October 11 to 18, in Paris, is the construction of the ideal road for heavy motor traffic. Though macadam with some anti-dust preparation will doubtless remain as the type of road for country highways, European experts are more and more of opinion that something more resisting will have to be employed for the main roads in the neighborhood of cities or on any highway having a large amount of traffic.

M. Chaix, the president of the Touring Committee of the A. C. F., is one of many in favor of a scheme of road construction consisting of a bed of cement five to seven inches in thickness, covered over with a layer of sand, then paved with smooth rectangular granite blocks, the interstices being covered with asphalt. A road on this system has been built in the neighborhood of Suresnes, in the suburbs of Paris, and although subject to very heavy traffic has remained in perfect condition. Such a road is naturally expensive to construct, and for a long time will never be regarded as other than a road de luxe. Its efficiency, however, is beyond question and has been so well proved that an extensive scheme is now on foot in the district to the north of Paris for the pulling up of the old, roughly laid granite blocks to be replaced by smooth ones on a bed of cement.

Though this type of road would doubtless be the ideal for automobiles, in the opinion of Dr. Guglielminetti, the secretary of the anti-dust league, it can never be very extensively adopted on account of its cost and the ill effects it has on horses. Though a fervent automobilist, Dr. Guglielminetti believes that the horse will be an important element on the main roads for a number of years and that some consideration should be had for his comfort. Asphalt, in the opinion of the anti-dust expert, would be more satisfactory than granite paving, for it produces neither dust nor mud, is silent and is easily and quickly repaired. The objection usually levied against asphalt that it is slippery in slightly wet weather is not a serious one, for there are methods of asphalting which entirely overcome this. This process is also more costly than macadam, the price of the latter in France being about $6,000 per kilometer, compared with $26,000 for a wood paved or asphalt road.

While the annual overhauling of Paris streets has been going on this summer it has been noticed that the portion of the Champs-Elysees reserved exclusively to automobiles was in excellent condition, while the side portions, used by horses alone, had been torn into strips until it was a mass of holes. The effect of the rubber tires was to wear the wood blocks equally smooth. The drippings of oil from the cars acted as a preservant, the remarkable result being that while the blocks used by horses could be torn out by a slight blow from the crowbar, the blocks that had never been pounded by a hoof were so hard that it was only with difficulty they were torn out of their bed.

NEW JERSEY GOVERNOR FAVORS GREAT OCEAN BOULEVARD

AT a banquet given him last Thursday night by prominent summer residents of the Northern New Jersey coast resorts at the West End Cottages, Long Branch, Governor J. Franklin Fort outlined a system of highways to be built and maintained by the State that, if carried out, will raise still higher New Jersey's good roads banner among those of her sister States.

First of all, Governor Fort proposed a great boulevard to extend for a distance of 127 miles along the ocean front, from Atlantic Highlands to Cape May. He said that for a considerable portion of the proposed route there were already fine gravel roads, and declared that by widening them and constructing the connecting stretches the proposed boulevard could be built at a cost of $300,000. The entire work could be completed in two years and much of it be ready for use by next season, provided the legislature made the appropriation at its next session.

In the opinion of the Governor the legislature could easily be persuaded to make the required appropriation were the cooperation of the inland counties secured. This he was confident could be obtained by including in the ocean boulevard project a scheme for connecting all the county seats by State highways. This would result in a system which would give 500 miles of roads built and operated by the State.

The cost of the annual maintenance of such a system would be but $300 per mile, or a total of $150,000.

In the course of his comprehensive speech Governor Fort touched upon New Jersey's present motor vehicle law. He declared frankly that the automobile had come to stay, and that the automobilist must be reckoned with and treated with reason by the legislature in its laws. The Governor then made the radical suggestion that the Governors of the State of Connecticut, New York, Pennsylvania, Delaware, and Maryland appoint commissioners to meet commissioners appointed by himself to discuss this whole question of automobile legislation and make recommendations for uniform laws on the subject a common-sense proposition that elicited enthusiastic applause from the seventy-five banqueters.

The chairman of the banquet, Jefferson Seligman, twitted the Governor on his recent speed-trap adventure. Speeches were made by Gen. J. J. McCook, Judge Wilbur A. Heisley, Isador Straus, Justice Victor J. Dowling and W. E. D. Stokes.

INSTRUCTIVE PROGRAM FOR GOOD ROADS CONVENTION

NEWARK, N. J., Sept. 7.—Announcement is made of the tentative program arranged for the two-days' session of the Good Roads' Convention at Atlantic City, September 25 and 26, by the Associated Automobile Clubs of New Jersey and the New Jersey Grange. There will be four sessions, one in the morning and another in the evening of each day. The evenings will be given up to the entertainment of the delegates and their friends by the Atlantic City Automobile Club.

The first session, that on Friday morning, will take up the general subject, "Good Roads." Among the points to be discussed under this heading are: "New Jersey Highways," "Good Roads from the Granger's Standpoint," "The Standpoint of the Dweller Along the Way," and "From the Automobilists' Point of View." Invitations have been sent out to speakers of note, and it is almost certain that favorable replies will be received in practically every case. The presence of Governor Fort is assured.

The second day will be given over to the consideration of the subject of road construction. Road authorities from this and other States will present papers based upon their personal experience in roads building. It is hoped that a demonstration of road-making machinery and dust-laying devices can be given in connection with the second day's sessions.

From the program as mapped out, this, like all such conventions, will go far to help the "good roads" problem and in addition will do a great deal to bring about a better understanding between the farmer and the automobilist.

THE AUTOMOBILE

THE DANGER OF NEGLECTED ROADS.

Hardly a day passes that does not give the newspapers an opportunity to record another serious, often fatal, "automobile accident." Of course, those who understand the conditions can usually see just how far the automobile was responsible in each case; but among less informed people these incessant reports are strengthening the belief that the average automobilist belongs to the same class as the parachute jumper and the "wild, death-defying" circus performer. Why some of our ordinarily responsible and clear-sighted papers think it worth while to foster this opinion for the sake of a little cheap sensation-mongering is rather hard to understand. However, the Toledo, O., *News-Bee* has the courage of its convictions, and it is convinced that "speed mania" is not always to blame. The case in point is the accident in which the Rev. George Vahey and Charles W. Pohlmann were killed, about a month ago, near Sylvania, O. The *News-Bee* quotes from Coroner Faber's verdict:

"The evidence brought out at the inquest convinces me that the road where the accident occurred was in dire need of repair, and that this is true in many other sections of the country. It shows conclusively that roads in general are not given the attention they should receive in view of the extensive automobile traffic nowadays. In a word, township trustees and county officials have not kept pace with the times. The accident was directly due to the fact that the chauffeur lost his way. The law provides that guide posts be erected at road intersections, but it is generally disregarded. Had there been a guide post at the point where the chauffeur turned upon the wrong road the accident would have been avoided."

This is plain speaking with a vengeance. But there are two facts which cannot be denied: First, that roads are made for the people who use them, and, second, that a large and constantly increasing proportion of road users are automobilists. Therefore, roads should be adapted for automobile traffic.

No one denies that some automobilists use the roads improperly, and this element figures largely in the accident list. But the evidence at Coroner Faber's inquest showed that the Rev. Vahey and Mr. Pohlmann were traveling at a reasonable speed. The road was simply a death-trap, and the county officials responsible for its condition should be held guilty of criminal negligence, at least. They are nearly on a level with the men who equip excursion boats with fraudulent life-preservers and put rotten fire-escapes on their tenement houses.

Nevertheless, it might be timely to reiterate a fact which is daily becoming more self-evident, and that is, that automobilists themselves must assist in bringing about a reformation of their own black sheep, who are really responsible for the spread-heading of all automobile stories which have even the semblance of an accident.

* * *

SOME EXTERNAL IMPROVEMENTS.

Improvements in the external appearance of an automobile, although of course not so important as improvements in its mechanism, still have—and rightly—a considerable influence on its success. Most buyers take for granted that the various makes of cars they are considering will run and give reasonable satisfaction, and this being the case, they are apt to give more attention to the esthetic side. Surely a man cannot be blamed for preferring a neat, well-proportioned, cleancut car to a clumsy, heavy-looking one, with odds and ends of the mechanism hanging out at unexpected places; and he will usually find that the designer who has been careful of the exterior of his car has been careful of the interior as well.

The most marked improvement has been effected on the dashboard. Once upon a time people used to talk of a "well-filled" dash, the equipment of which might be inventoried as follows: ten oil-sight feeds (more or less); one large oil cup; one hand oil pump; two or three oil cocks, for various purposes, and several yards of pipe; one water pressure gauge; one air pressure gauge; one hand air pump; some more cocks; auxiliary air lever; ignition cut-out button, and perhaps some more. When the proud owner had added a speedometer, odometer, and clock, the result was indeed wonderful to contemplate.

But nowadays most makers limit themselves to the sparkcoil and switch, encased in a polished box to match the dash; a neat row of sight feeds may be permitted, and perhaps an auxiliary air lever, but that is all. Mud pans are now universal, and many cars have sheet-metal aprons between frame and running boards, concealing the unsightly exhaust pipe and muffler. Bodies are not only more comfortable and convenient, but their designs and coloring are in better taste. And these small improvements have done a great deal toward bringing the automobile into public favor.

LICENSED ASSOCIATION MANAGERS MEET.

The all-day session of the board of managers of the Association of Licensed Automobile Manufacturers, held in New York last week, had for the most part to do with the Madison Square Garden show matters. Much enthusiasm was evoked by the scheme of decoration adopted by the show committee as explained by Col. George Pope, its chairman. A magnificent triumphal arch is to be a conspicuous feature. There will be a new sign scheme, which will not only be more convenient to the public, but also enhance the beauty of the background. The structural arrangements will provide much additional floor space and a more effective ensemble as well. Space allotments for the show were made, but as usual not made public.

The resignation of Harry T. Clinton, head of the agency and publicity departments, was presented and accepted. In future E. P. Chalfont, assistant general manager, will have charge of the agency department, and Coker F. Clarkson, secretary of the mechanical branch, will look after the publicity.

It was announced that the recent aggressive policy of the association prohibiting dealers from handling unlicensed cars met with full support and will be continued with rigid enforcement. The committee in charge of the 1909 edition of the "Hand Book of Gasoline Automobiles"—which is the sixth of the series, reported progress. Members represented were:

The Autocar Company, Marcus I. Brock; Buick Motor Company, W. C. Durant; Cadillac Motor Car Company, W. C. Leland; Corbin Motor Vehicle Corporation, M. S. Hart; Chalmers-Detroit Motor Company, R. D. Chapin; Electric Vehicle Company, H. W. Nuckolls; Elmore Manufacturing Company, J. H. Becker; H. H. Franklin Manufacturing Company, G. H. Stilwell; Hewitt Motor Company, E. R. Hewitt; R. C. Glidersleeve; Locomobile Company of America, S. T. Davis, Jr., A. W. Robinson; Lozier Motor Company, H. A. Lozier, Jr.; Matheson Motor Car Company, C. W. Matheson; Northern Motor Car Company, V. M. Gunderson; Packard Motor Car Company, H. B. Joy, M. J. Budlong; Pesriess Motor Car Company, L. H. Kittredge; Georgs N. Pierce Company, Charles Clifton; Pops Manufacturing Company, C. E. Walker; Pops Motor Car Company, George Pope; Royal Motor Car Company, E. D. Shurmer; Selden Motor Vehicle Company, R. H. Salmons; F. B. Sterns Company, F. B. Stearns; Stevens-Duryea Company, C. C. Hilderbrand; Studebaker Automobile Company, W. E. Metzger; E. R. Thomas Motor Company, E. R. Thomas; Waltham Manufacturing Company, E. S. Church, O. G. Bechtel; Winton Motor Carriage Company, Thomas Henderson, E. P. Chalfant, assistant general manager.

HERE'S A GOOD KIND OF LOCAL SHOW.

HARTFORD, CONN., Sept. 7.—The show held under the auspices of the Hartford Automobile Dealers' Association at Charter Oak Park in connection with the grand circuit horse races and the Connecticut State fair was accorded an auspicious opening to-day. The weather was simply perfect and the crowd all that could be desired. Without the gates (no cars being permitted within the enclosure) were hundreds of cars neatly parked. The attraction is housed under the roof of the huge skating rink.

The various exhibitors have made good use of their space and many of the displays are very attractive. The Miner Garage Company display the Knox and Buick, and though agents of the Pierce, a car of that make could not be secured for the opening. Brown, Thomson & Co. display the Packard "18" and "30," Stevens-Duryea four and six-cylinder cars, and the Cadillac. The Corbin cars are well shown up, and the Palace Automobile Station offers the Oldsmobile, Thomas new six and four, the Autocar, and the E. M. F. Robert Ashwell displays the air-cooled Franklin, and Dunbar & Mansir of Holyoke, Mass., show the two-cycle Elmore. The Legate Manufacturing display the two-cycle Atlas in touring runabout and taxicab models. A. W. Peard shows the Overland in four and six models.

The accessories are well displayed and those of Brown, Thomson & Company to excellent advantage. Interest naturally centers in the 1909 models, and the Packard "18," E. M. F., Knox, and six-cylinder Thomas are centers of attraction. The Elmer Automobile Company make an effective display of the six and four-cylinder Fords. The Electric Vehicle Company display the 29-horsepower Columbia gas model.

MINNESOTA AUTOISTS MAY HAVE HARD FIGHT.

MINNEAPOLIS, MINN., Sept. 7.—Minnesota autoists will have a hard legislative fight this year in the effort to revise the automobile laws of the State. There is a general demand for the re-establishment of the system of State registration and State licensing, which was abandoned two years ago, when the legislature passed a law authorizing cities and municipalities to license and number cars. The secretary of State, in his report this year, strongly urges a return to the old system.

The Minneapolis Automobile Club has a new scheme, however, upon which its members are uniting, and which they promise to fight for upon the opening of this Winter's legislative session. It is proposed to exempt the automobiles from all taxes under the personal property assessments, and to levy in lieu of such taxes a State registration fee of from $5 to $75, based on the power and weight of the machine. This fee it is proposed to use for road improvement, as a State and county fund. The plan has the support of the Minneapolis automobilists, but will undoubtedly meet some opposition.

Secretary of State Schmahl, in his annual report, says:

"In view of the repeated requests from residents of Minnesota, as well as from other States, for licenses to operate automobiles in Minnesota, I cannot too strongly recommend to your honorable body the enactment of a uniform law governing the licensing of automobiles in Minnesota.

"The license, in my opinion, should be issued by this department and a uniform fee of $1.50 or $2 per annum could be charged without injury to the owner, and with great benefit to the State. At the present time there is absolutely no uniformity in the numbering of machines; each municipality or township organization has its own system of numbering, and as a result a large number of machines operated in Minnesota have precisely the same number, which must necessarily work more or less inconvenience to police and other officers of the law seeking to ascertain the ownership of certain machines.

"This department is daily in receipt of requests from residents of the State, as well as foreign residents, for these licenses, and the provisions for a State license should be made at as early a date as possible by your honorable body. There are probably in the neighborhood of 10,000 automobiles in this State, and an annual license of $1.50 for the operation of each machine would bring a fair return into the State treasury."

CONGRESSMAN JENKINS DEFEATED.

MILWAUKEE, WIS., Sept. 5.—Automobilists here are much interested in the results of the primary elections, of which the most surprising development was the defeat of Congressman John J. Jenkins by Irvine L. Lenroot. Congressman Jenkins was chairman of the Judiciary Committee of the House during the last Congress, and it was before his committee that Thaddeus Terry, chairman of the A. A. A. Legislative Board, made his argument for the Federal registration bill. The story of that argument is now ancient history; but it will be remembered that although Mr. Terry came forth with flying colors, having answered every objection and silenced every opponent, yet the bill which he championed was never reported. Congressman Jenkins was considered somewhat obstinate in the premises, and automobilists opposed his reelection. Now it looks as though they may have held the balance of power.

HONORING THE ROUND-THE-WORLD WINNER.

PHILADELPHIA, Sept. 7.—Mounted upon a dais in the handsome salesrooms of the Bergdoll Motor Car Company, at Broad and Wood streets, the New York-to-Paris Thomas reposed in state for two days last week while thousands of local motor enthusiasts paid homage to the victorious car and its driver. On Thursday night the big banquet hall of the Hotel Walton was packed to suffocation by those anxious to hear Orrel A. Parker's illustrated lecture of the long race. After the lecture there was a banquet, at which Louis J. Bergdoll, Fred Vanderhoof, George T. Verrault, Driver George Schuster, and several others had a few words to say regarding the race. Henry L. Hornberger presided. The lecture and banquet were under the auspices of the Quaker City Motor Club.

CLUB DOINGS IN ACTIVE AUTO CENTERS

DRIVING PRECEPTS FOR SANE AUTOISTS.

CHICAGO, Sept. 7.—President Ira M. Cobe, of the Chicago Automobile Club, in the bulletin of that organization, gives the following excellent advice to automobilists to drive with due consideration to other users of the road:

Rsmember that greater liberty is enjoyed by automobilists in Chicago than in any other largs city in the country. Rarely is an arrsst made except in flagrant cases.

Always slow down before turning corners, and look to ses that no machins is immediately behind you.

Nevsr turn directly around in ths street without warning.

Do not dart ahead of vehiclss in crowded thoroughfares. A few seconds' gain is poor compensation for the risk run.

Remsmber that women and children ars likely to do the wrong thing when danger threatsns. It is better to slow down or stop than to depend upon your skill at dodging.

As between injuring a pedestrian and damaging the car, smash the machine every time.

To run away after an accident is to confess yourself a coward, and an unfit associate for gentlemen.

An automobile hits hard. A serious or fatal accident will spoil ths sport for you for a lifetime. Let your motto be, "Safety first and speed afterward."

Drinking and driving should never be indulged in the same day. If you must drink, do your riding in a hack.

Finally, remember that, notwithstanding your car weighs 3,000 pounds, and a psdestrian 150, this is not a case where might makes right. Don't think that because you toot your horn it is necessarily up to the man on the street to do the jumping.

HERE IS A MODEL CONNECTICUT SIGN.

HARTFORD, CONN., Sept. 7.—The Connecticut Automobile Association is wide awake as to the practical needs of the motoring fraternity. Temporary signs will be erected immediately throughout tbe State wherever road improvements are being carried on. Tbese signs will contain full road directions. Speaking of signs, that above the South Glastonbury post office meets all demands. The background is black and the letters are gold. Tbe sign reads: "U. S. Post Office, South Glastonbury, town of Glastonbury, Hartford County, Conn., population 4,800, Hartford 9 miles, Middletown 9 miles." There one has the whole story briefly told with directions indicated. Vice-president Gillette of the Automobile Club of Hartford while secretary of the A. A. A. endeavored to have the government erect signs of this nature over its post offices tbroughout the country, but the contention at that time appears to have been that the federal government would not be benefited and the matter was allowed to drop. The sign above referred to can be seen from a distance.

Gilbert F. Heublein has returned from an extensive trip through the British Isles. Mr. Heublein dined the contest committee of the Automobile Club at the Heublein last evening. Mr. Heublein's daugbter is the wife of Percy Martin, superintendent of the English Daimler factory, and during his stay toured with Mr. and Mrs. Martin.

TOUR OF THE MICHIGAN CLUBS.

DETROIT, MICH., Sept. 7.—Keen interest is being displayed by clubs all over the State in the tour of the Michigan State Automobile Association scheduled for September 24-26. From present indications not less than one hundred cars will take part in the three hundred-mile contest.

Flint motorists will join the Detroit delegation and make the start from here, reaching Grand Rapids on the 24th. That evening a banquet will be given in the Furniture City, and on the following morning all the different clubs will leave Grand Rapids for Detroit. This will complete the tour for Detroit and Flint, Battle Creek, Grand Rapids, Kalamazoo and other motorists being required to run back to Grand Rapids in order to cover the 300-mile course. Several valuable trophies in the way of cups are offered participants. The Michigan association, Edwin S. George, and S. D. Waldron are donors.

PENNSYLVANIA'S FEDERATION IS ALIVE.

PHILADELPHIA, Sept. 7.—On Friday morning next there will be held at the handsome home of the Automobile Club of Germantown a meeting of the executive committee of the Pennsylvania Motor Federation and the presidents of the various clubs affiliated witb that organization to inaugurate a plan to bring about the passage at the next meeting of the State Legislature of new automobile and road laws.

President Robert P. Hooper, of this city, arranged the meeting, which will be held in the morning at 11 o'clock. The committee members and the club presidents will meet at the Union League and will be taken to the Germantowners' quarters in automobiles.

After listening to the reports of the various committee chairmen and the subsequent discussion, a plan of campaign will be decided upon, witb the result that the various club representatives will return to tbeir homes witb well-defined ideas as to how to go unitedly to work througbout the State in an effort to bring about a betterment of motoring conditions generally. Those attending the meeting will be the guests of the Germantown club at luncheon.

A. C. OF PHILADELPHIA DOING EXCELLENT WORK

PHILADELPHIA, Sept. 7.—The Automobile Club of Philadelphia is particularly active these days and is accomplishing much for the general good of automobiling in the vicinity of this city. During August 317 warning signs of various kinds were placed by the Roads, Maps and Signs committee.

The membership committee reported the election of 29 new members. The report of the law and ordinance committee contains the following pertinent advice:

"Your Committes begs to call your attention to the fact that in order to securs fair treatment we must be fair to others upon the highway and uss consideration in operating our machines. Public sentiment is without doubt beginning to concede that automobiles may be operated safely at a speed considerably in excess of that which may be permitted to horse-drawn vshicles.

"Every accident due to rsckless or negligsnt driving retards the development of this idea, but we wish also to point out to you that discourtesy to drivers or riders of horses and pedestrians, bscause of its greater frequency, is almost as detrimental.

"Give others their fair share of the road, turn out in ssason, do not drive under a horse's nose, do not pass horse-drawn vehicles at an excessive rate of spsed, and insist on your chauffeur's observing the same rules, and you will materially aid those who are working to secure the freedom of all motorists from annoying restrictions."

HARTFORD CLUB CLIMB, NOVEMBER 7.

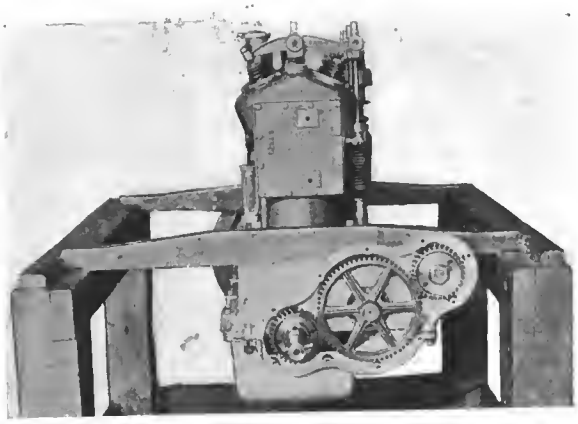
HARTFORD, CONN., Sept. 5.—The contest committee of the Automobile Club of Hartford devoted nearly all of to-day scouring Hartford county for a good hill for the forthcoming climb. Two weeks ago it was decided to make use of Avon mountain, one of the hardest climbs anywhere in this State, up the side of a mountain in fact. At a meeting of the board of governors early in the week the matter of the climb was thoroughly tbrashed out and it was deemed wise to conduct a still further search for a real hill. Accordingly grades in Newington, Griswoldville, and Glastonbury were inspected. One particularly stiff one was located at South Glastonbury, but it was considered inaccessible and the committee passed it. Another very promising slope was located on the Marlborough-Colchester road and this was much favored. The grade was tested and measured, and it was a toss-up between the Glastonbury hill and the Avon mountain course. Then the committee toured away out to Avon and tested out the hill. The first trial proved conclusively that the course at the last turn is a dangerous one, but after careful consideration it was decided that the Avon route will be the scene of the forthcoming event. The last turn will be banked to preclude the possibility of skidding.

Model 9K of the 1909 Stoddard-Dayton Line, with Top and Detachable Tonneau, Which sells at $2,700.

THE Dayton Motor Car Company, Dayton, O., since its inception in 1905 being a constant exponent of the medium-priced machine—the $2,000-$2,500 type—has, as if a leader in the forward march of price reduction, ready for next year three types of cars that embrace the $1,500-$2,500 manufacturing gamut, all of which are alike in chassis design, in the grade of material used and in the finish given, differing only in the size of parts to meet the demands for cars of different horsepower, different speed proclivities and different passenger carrying capacity.

Scarcely one of the 1908 Stoddard-Dayton principles have been discarded, but not a few of them have been amplified in minor details, all of which are footsteps in the path of evolution that the designer, Edwards, has been forging the car along since its inception. The valve-in-the-head motor with one rocker arm for the intake and exhaust valve of each cylinder remains unchanged; the contained crankcase lubrication shows detail modifications, the cone clutch with its leather facing is in place; so is the selective gearset; the shaft drive, and the double ignition system. In the list of alterations come the employment of integral water jackets for each cylinder pair, in place of the copper water jackets employed during this season. These new water jackets have large end plates secured by set screws with fiber gaskets between them and the cylinder walls, which plates allow of a simple twin casting and give good opportunity for removing core sand. Such jackets offer a simpler construction than copper. Locating of the fan pulley in rear of the half-time gear cover on the forward end of the motor has the advantage of not interfering with the removal of the aluminum plate forming the front of the gearcase and further eliminates the boring of the cover for the fan shaft extension which would give an opportunity for an oil leak at that point. A choice is given of four magnetos, two types of Bosch, Witherbee and U. & H., the latter a German product. The transmission has been improved by locating the gear shift lever outside of the frame at the right, motor devotees recalling how heretofore it was located in the floor board inside of the frame member, a location used to avoid perforating the side member of the frame for the lever of the change speed shaft and the brake lever shaft. While the frame side member is now perforated it is strengthened by the presence of a semi-oval bracket bolted to the outside of the frame and which carries and entirely encloses the change speed lever's lower end as well as taking the sector for the emergency brake lever. The bracket is a mud and dust-proof affair, entirely enclosed at its lower end, the only opening in it being the slot in which the change speed lever operates. An improvement in the three-speed selective gearset is the lengthening of the bosses on the transmission case for carrying the Timken roller bearings as well as using chrome nickel steel for the propeller and rear axle drive shafts where nickel and high carbon steels were previously in vogue. The running gear has undergone several modifications all taking the nature of enlargements. The side members of the frames have been increased in vertical depth 1-2 inch and the horizontal webbs added to the extent of 1-2 inch; brake drums on the big car are made 14 inches in diameter, where 11 1-2 sufficed, and the width has been raised to 2 1-2 inches. The drums are steel stampings instead of malleable iron castings. Road wheels, while enlarged in diameter in the small car, have been increased in strength by the use of twelve and fourteen spokes in front and rear and increasing the spokes to 1 7-16 inches in width. The side strut roads from the frame members to the rear axle casings are now made with a bolt and eye connection at the frame instead of the ball-and-socket joint of previous seasons. The steering connections now pass over the front axle at the right front of the car instead of under the axle, a change used on the majority of the 1908 cars and which takes this most important member of the steering mechanism out of the reach of

Gearshaft Control, Outside of Frame.



Three Motor Gears Instead of Four This Year.

road obstructions. The tie rod between the steering knuckles is in front of the axle. In the body work a change is covering the wood construction with cheap metal instead of a special textile fabric, the apparent aim being that while textiles are subject to variations in climatic conditions in various countries, sheet metal is not, the result being that a better enduring finish is possible. The body lines are practically as at present, except that the tonneau rear is a straight line from the base of the seat to the top, whereas it had a slight reverse curve; there also is a simplification of the tonneau door lines and the tonneau side lines at the same place. The different models are all alike in the employment of the oval radiator filling cap—a distinguishing Stoddard-Dayton mark—the straight wood dash and the throttle and spark controls or sectors under the steering wheel rim at the left where they may be controlled with the fingers of the left hand while the right hand is engaged in making changes of speed are other marks by which the cars for 1909 may be recognized.

Before going into detail on several of the systems in vogue on Stoddard-Dayton cars an enumeration of the models will serve as an introduction to some of these systems. The three types 9H, 9A and 9K carry motors with the following sizes: 9H, bore 3 7-8 inches, stroke 4 1-2 inches, and rated at 24-horsepower, A. L. A. M.; Model 9A, bore 4 inches, stroke 5 inches, with a formulæ rating of 25.6; and 9K, the same as at present, bore 4 3-4 inches, stroke 5 inches, giving 36.1 horsepower. The company gives a little higher horsepower rating than these: 9H, 25 horsepower; 9A, 35, and 9K, 45. The little 9H has undergone the most changes, now having the valve in the head motor, a wheelbase of 103 inches instead of 92, 32 by 3 1-2-inch tires, chrome nickel transmission, drive shaft and rear axle parts, larger brakes, a heavier frame and the motor stroke increased from 3 3-4 inches to 4 1-2 inches. This little car has body lines identical with the bigger brothers and is made with a detachable tonneau as well as regular two or three-passenger roadster. The Model 9A is a new style, coming as a half-way step between the little Model 9H and the big Model 9K. It is a five-passenger touring car with 105-inch wheelbase and 34 by 3 1-2-inch tires. As a roadster it is known as 9C, having a wheelbase 110 1-2 inches long in order to give a good suspension of the motor with relation to the front axle and introduce a rakish steering column. The big car Model 9K is the present Model 8K put through the metamorphosis process for 1909, as already delineated. Its wheel base measures 120 inches, and when fitted for seven passengers carries 34 by 4 1-2-inch rear tires and 4-inch sizes when fitted for five passengers. As a roadster this car is known as Model 9F and uses a 113 1-2-inch wheelbase.

No part of the motor in all models offers greater interest than the oiling system, which in brief is a crankcase contained system, in which the lower half of the crankcase is divided horizontally by a sheet metal partition, that part beneath it being an oil reservoir in which a vertical plunger pump driven by eccentric off the camshaft and which pump delivers oil into a manifold attached to the upper half of the crankcase. From this manifold the oil is delivered to the crankshaft and camshaft bearings and the timer shaft. The overflow from these leads falls into the upper half of the crankcase and is refiltered into the oil reservoir. The system is therefore not a splash one but a positive transporting of oil to every motor bearing as well as to the cylinder walls. The manifold distributes oil by leads to the end bearings of the crankshaft, to the center crankshaft bearing, to the end bearings of the camshaft, to the timer shaft and to a sight gauge on the dash. Fig. — shows how each crankshaft bearing is lubricated. The oil lead *A* pours its contents into a pocket *B* above the bearing. In the bottom is a hole conducting the oil direct to the bearing but which outlet is not so great as the supply of the pipe *A*, with the result that the pocket overflows as indicated, the surplus dropping into a bronze ring *C*, carried on the throw of the crankshaft. This ring has a peripheral groove specially designed for catching this overflow and has an elliptical extension carrying an outlet *E* through which the oil finds its way into the bored crankpin of the crankshaft, centrifugal force driving the oil through this course. The crankpin is bored with an outlet *D* to lubricate the lower bearing of the connecting rod. In this system the oil has to be conveyed to the upper connecting rod bearing, which is done by attaching a copper tube to the side of the connecting rod. The rod at its lower end has an opening through the lower connecting rod bushing and at its upper end a similar opening through the wristpin. The oil once raised into the wristpin flows through it and reaches the cylinder walls which it lubricates. By means of an opening in the top of the wristpin oil is by the reciprocation of the piston thrown through this hole and, dropping, finds its way to the end bearings of the wristpin. Thus is the lubricating liquid positively conducted to the three crankshaft bearings; thence to the lower bearings of the four connecting rods, thence to the upper bearings of the connecting rods, and thence to the cylinder walls. It will suffice to say that the camshaft is similarly cared for, the overflow soon finding its way back to the reservoir.

A few words as to the care in oiling the vertical commutator

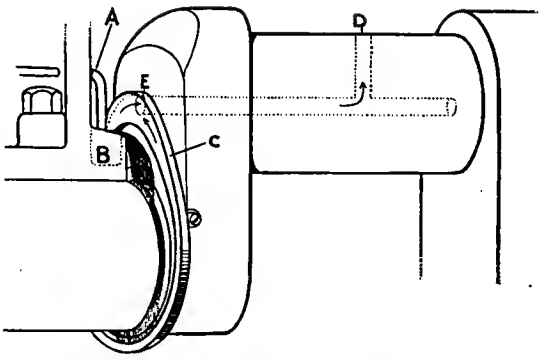
Attachment of Engine Water Pipe to the Cylinder.

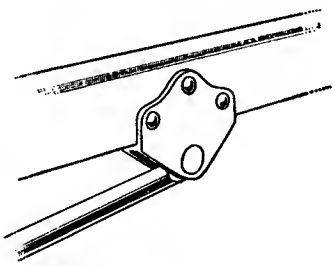


Lubrication of Crankshaft and Lower Connecting Rod Bearing.

shaft at the side of the motor is necessary. The hardened commutator shaft carrying on its lower end a driving bevel and on its upper end the revolving contact is supported in an aluminum casting within which is a bushing. A separate oiler lead pours lubricant into a cup ring receptacle on the base of the casting in which are holes to conduct the oil to the revolving shaft. On the shaft is a spiral groove which carries the oil upwards, distributing it through the entire ascent. The surplus at the top finds its way to the center of the mechanisms lubricating the plunger and other parts and is conducted to the space between the bushing and the aluminum castings in which it falls to the base again ready to overflow and lubricate the central camshaft bearing.

The plunger pump on which rests the burden of this complete circulation is carried in the lower half of the crankcase. The reciprocating plunger carries a roller on its top which contacts with the driving eccentric on the camshaft. This eccentric forces the plunger down and a spring lifts it. During the upward stroke oil enters the casing through a series of holes immediately beneath the plunger when at the top of its stroke. On the down stroke oil is forced out into the crankcase until these holes are closed by the plunger, after which the oil escapes through a lead to the distributing manifold already, its passage being by a check valve which prohibits its return. The pump can be dropped by removal of a casing secured to the base of the crankcase by three bolts. The pump has a 7.8-inch diameter and 3-4-inch stroke. Locating the pump so calls for 9 inches of external tubing, the only oil pipes seen around the motor, this length connecting from the exit of the pump to the upper part of the crankcase where connection is made with the distributing manifold. Attention is drawn to the oil gauge on the crankcase, which tells the level in the oil reservoir. It is a tube extending into a pocket in the base of the crankcase, a cork resting in the bottom of the tube and connecting by wire with a "flyer" in the aluminum top or gauge part. So delicate is the device that the addition of a pint of oil to the reservoir supply results in a lifting of the "flyer." The oil is fed to the crankcase or oiler through a filler tube rising to the top of the cylinders at the side. On the other parts of the car are compression grease cups in numbers. The valve rocker arms carry two each; the fan shaft has one, others are on the pump and magneto shafts, and in a review of the chassis they are positioned on universal joints, steering gear parts and spring bolts.

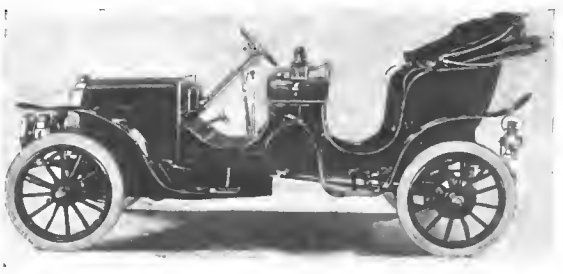
The manufacture of the upper half of the crankcase has been facilitated by removing the elevations on which the valve lifter rod guides rested in 1908, so that now the part of the crankcase on which these rest is on a level with the part supporting the four cylinders, so that the milling of all these parts is done with one operation instead of two as formerly. This year four gears were needed in the front of the motor, the camshaft gear being a double one, the large diameter part meshing with the camshaft pinion and the smaller diameter part for driving the pump and magneto shaft. By a nicety of dimension it is possible now to employ but three gears, the crankshaft pinion driving the camshaft gear and this in turn driving the magneto shaft.



Attachment of Radius Rod Bracket to Frame.

The Stoddard-Dayton cars are essentially homemade products. A foundry owned and operated by the company furnishes all of the cylinder castings, all the aluminum castings for the crankcase, gearbox, commutator support and all of the brass parts. In the steel building the side members of the pressed steel frames are forged, burnished and mounted together; in the same building all parts of the springs are made; side by side with the forges for making gear blanks and frames are those for making the one-piece front axles, the steering gear parts and the score of other forged parts that enter into the sum total of the car. All gear cutting is done in the machine shop, bodies are all made in a separate compartment. This delineation of home manufacture could be continued, but it will suffice to state that, with the exception of the electrical parts, carbureter, wheels and Timken bearings, the car is a Stoddard-Dayton product.

Model 9H 25-horsepower Which Sells for $1,500.



Model 9N Victoria Phaeton, a $2,000 Pattern.

NOW THE AUTO THIEF IS IN EVIDENCE.

DETROIT, Sept. 7.—The epidemic of auto thievery sweeping Detroit has roused local motorists to a sense of their helplessness under existing conditions, and plans are being laid looking toward legislation that will land the man stealing an automobile behind the bars just as surely as it now does the one who steals a loaf of bread.

There was a time when the owner of a machine felt secure if on leaving his machine he removed the switch plug. Not so now, however. The modern auto thief apparently carries a complete line of parts with him, and is able on a moment's notice to supply the missing article.

Within a week no less than half a dozen high-priced machines have been stolen as they stood on the streets, and several private garages have been broken into. In nearly every instance the machines have been recovered where abandoned when they broke down or the fuel supply was exhausted. Several are still numbered among the missing, however. That the thieves are not wholly devoid of a sense of humor is shown by the fact that John Dodge, of the Ford Motor Co., and Wm. F. Metzger, of the Everett-Metzger-Flanders Co., are among the victims.

At present there is no law covering the theft of an automobile, and the thief, even if caught with the machine in his possession, can only be given a slight fine or a short sentence at the workhouse. This fact has emboldened the thieves, but their harvest will soon be at an end if legislation planned becomes a reality.

CLEVELAND POLICE AFTER SPEEDERS.

CLEVELAND, Sept. 8.—Every "crossing cop" in the city holds a stop-watch in his hand; the bicycle squad has been increased 300 per cent.; orders have been issued to spare no motorist caught speeding. This, in short, is the condition of affairs in this city since Chief of Police Kohler recently decided that speeders belonged in the police list of "undesirables." It may be interesting to note in passing that the other "undesirables" consist of tramps, pickpockets, confidence men, burglars, yeggmen, suspicious characters, released convicts, etc.

Just what started the war is not known, as there had been very few complaints of speeding. But the Chief started in to "clean up the city of all undesirable characters before Winter," and so the poor man who drives a motor car finds himself up against it.

BALTIMORE DOESN'T WANT 'EM, YET.

BALTIMORE, Sept. 7.—Automobile fire engines, hose wagons and trucks will not be used in the Baltimore department yet awhile, as Chief Horton has decided that the horseless machines are not yet reliable enough for fire-fighting purposes. He has asked the Board of Fire Commissioners to furnish himself, his deputy chief and the district chiefs with steam automobiles to replace the present horse-drawn carriages.

BALTIMORE'S CLUB HELPING POLICE.

BALTIMORE, Sept. 7.—The crusade against those autoists who persist in speeding their machines within the city limits and on the crowded thoroughfares of the counties have had to pay numerous fines the past week. This crusade is a joint affair with the Automobile Club of Maryland, the Grand Jury and the motorcycle police on the one side and the autoists who attempt to evade the law on the other. Several local dealers have been among those who have fallen into the trap and they have been compelled to pay from $10 to $25 and costs for their sport.

KOKOMO'S FIFTEENTH AUTO ANNIVERSARY.

KOKOMO, IND., Sept. 2.—With a program of races and other events, the fifteenth anniversary of the building of the first gasoline automobile by Elwood Haynes of this city, was celebrated here to-day. The day was made a holiday, business houses and factories closing and hundreds of persons from all parts of the State gathering for the celebration.

The celebration was arranged by the Kokomo Automobile Club, assisted by business men, and cash prizes were awarded to winners of the various events which were held on downtown streets. The principal streets were roped off and for several hours were in the possession of automobiles and their drivers.

About 100 automobiles appeared in the parade, which was led by a band and a Rapid Pullman sight-seeing car carrying a party from Indianapolis. Many of the cars were artistically decorated, although the decorations consisted largely of flags and bunting.

OHIO REUNION OF OLDSMOBILERS.

AKRON, O., Sept. 5.—Seven miles of Oldsmobilers came from Cleveland, and their owners, with many others from other cities, attended the "grand reunion" of the Oldsmobile owners given by the Oldsmobile Company in Akron and at Long Lake. It was perhaps the largest procession of Olds cars ever seen in Ohio. Fifty-four cars came from Cleveland, and there were seventy-eight machines in the grand parade on the principal streets of the city and to Young's Hotel at Long Lake, where a sumptuous chicken and fish dinner was served.

The reunion was brought here because the Akron agents, Auble & Wood, of the Akron Automobile Garage Company, are the oldest agents of the company, A. Auble, of the local company, having been its agent since 1900. He has added to his fame by driving a perfect score car in the recent A. A. A. tour, and he will also drive a 1909 model in the endurance run starting Claude Foster. Another car present was the first car built with four-inch wheels for pneumatic tires. Among the cars with out of Toledo next Tuesday. This model was driven here by histories present were the *Mudlark* and Frank Work's *Wanderlust*.

After the drive to the lake and a photograph taken, a number of interesting contests were had, the slow race of cars on high gear exciting the most attention.

Photograph Taken at Long Lake, near Akron, O., of the Participants in the Oldsmobile Reunion.

Rambler Cars Being Tested on the Factory's Tarviated Half-mile Track.

The Factory Testing Track.—Most automobile manufacturers maintain a track of some sort where they can test new machines unhampered by local speed restrictions, but when these are constantly used by cars at high speed the problem of keeping them in repair often becomes pretty serious. The Thomas B. Jeffery Company, at their factory in Kenosha, Wis., had considerable trouble from this source, and experimented for some years with macadam under oil treatment and other road preparations, but all were found unsatisfactory until the Tarvia process was adopted. As every Rambler car, before being delivered to the purchaser, is run for about two hundred miles, this makes some fifteen or twenty cars running at high speed over the half-mile track every hour in the day. On the ordinary macadam track holes would immediately appear and the dust would be unbearable. Since Tarvia has been used, however, the track is entirely without dust, the surface coating makes it impervious to water and it is so elastic that the wear on the tires of the car being tested is greatly reduced. The success of the preparation on the Rambler track was so marked that it is now being used on all the nearby roads.

G & J Tires Reduced.—"It's a long story briefly told," said the sales manager of the G & J Tire Company, when asked for an explanation of the reduction in prices which took effect September 1. "To manufacture a moderate output requires precisely the same overhead expense for factory administration as a big output, and practically the same selling expense is involved. The 1908 G & J tire, when brought out last fall, met with such favor that we were encouraged to nearly double the already large equipment we had installed to manufacture it. Another important factor heretofore has been the large number of replacements required under the guarantee put on the tire. Our guarantee is still there, but our replacement department has been practically idle this summer. The tires have stood up so well that replacements have been an insignificant item of expense. All these things have naturally reduced the cost of production, and as soon as we became certain of this, we decided that the quicker we gave the consumers the benefit of the reduction the better it would be for us and for the automobile game in general."

Pierce Arrow Changes.—1909 Pierce Arrow cars will have the change-gear lever at the side of the car instead of on the steering column, and will also have a four-speed selective gear instead of the three-speed progressive type used heretofore. In explaining this change Col. Charles Clifton, the head of the Pierce Company, says: "We are firmly convinced that our old style was all that could be asked for in the way of a gear shift, but it was a question of our company against the world. The public has been educated to the idea of the selective gear, and we found it easier to make our cars conform to their way of thinking than to attempt to swing the balance of opinion our way. We are using the four-speed type because the public has been taught to look for this in cars of our power."

Exit the Tire Pump.—Not satisfied with having relieved Winton users of the arduous work of cranking, thanks to his self-starting device, Mr. Winton has gone a step further and abolished the tire pump. Attached to the self-starting cock on the dash of the new Winton Six is a nipple to which the user screws a rubber tube, the other end of which he attaches to the tire in need of inflation. Then he opens the cock and takes a rest, while compressed air from the starter tank rushes into the tire and fills it up. No one who has ever pumped up a tire on a hot summer day need be told what a convenience this is.

Firestone Salesmen's Reunion.—The annual meeting and reunion of the salesmen of the Firestone Tire and Rubber Company was held last week at the company's headquarters in Akron, O. There was a conference Thursday morning at which the past year's labors were reviewed and plans were outlined for the coming season. In the afternoon the gathering was taken to Summit in launches, and that evening they attended the theater. Friday evening the annual dinner was held at the Portage Country Club, and Saturday the conference was finally concluded.

Reo Stockholders Meet.—The annual meeting of the stockholders of the Reo Motor Car Company was held last week in Lansing, Mich., and the report shows the past year to have been the most successful in the history of the company, in spite of the industrial depression. The total volume of business during the last fiscal year amounted to $4,800,000. The officers of the company are the same as last year, namely: President and general manager, R. E. Olds; vice-president, Reuben Shettler; secretary and treasurer, E. F. Peer; general superintendent, R. H. Scott, and cashier, D. E. Bates, these also constituting the board of directors.

Look Out for St. Louis.—Benajmin Gerdleman, the St. Louis agent for the Jones Speedometer Company, has just secured an order from the police authorities of that city for the complete equipment of the motorcycle squad. The speedometer which will be furnished is practically the same as that used on automobiles; it is attached to the handlebar and driven by flexible shaft and gears. The scale reads to sixty miles an hour. Speed enthusiasts had better keep their eyes open now, for the cops "will get them if they don't watch out."

A New Continental Tire.—J. M. Gilbert, manager of the Continental Caoutchouc Company, New York, announced recently a new type of Continental, to be known as the "A-C" Flat Tread. Although sold at regular round tread prices, the new tire will have a straight guarantee of 3,500 miles service. The surface of the tread is corrugated, making it cling to the ground and giving greater speed. This corrugated tread also prevents skidding, and it is claimed that chains will not be needed when it is used.

Premier Century Run Ends.—The Premier Century car which started June 1 to cover 100 miles for 100 days, completed last week its one hundredth day's run and is now in Chicago little the worse for wear. It has covered in all more than 12,000 miles over all kinds of roads, through mud and sand and over mountains. President H. O. Smith of the Premier Company intends to have some Western club appoint a technical committee to examine the car after it has been taken apart.

A Fast Long-distance Tour.—Harry W. Byron of Mercersburg, Pa., has just arrived in Portland, Me., in his six-cylinder Franklin. He traveled 1960 miles in twelve days, running on an average ten miles a day. Mr. Byron declares that of all State roads those of Pennsylvania are the best. He attributes this to the fact that the roads are not so wide as others, but are crowned higher and rolled wet. They are especially good in the northeastern part of the State.

An 1897 Model for Sale.—The first automobile police patrol used in the United States, that of Akron, O., is offered for sale because of the purchase of a new and more modern machine. It was built by the city electrician, F. F. Loomis, in 1897, and has been in service ever since. In the riot of 1900 it was wrecked and thrown into a ditch, but was repaired and has since carried many hundreds of unhappy prisoners to the calaboose.

Ajax Tires Lower.—The Ajax-Grieb Rubber Company, of Trenton, N. J., has announced a material reduction in the prices of their tires for 1909, to take effect immediately. This has been made possible by largely increased production. For months past the company's plants have been working day and night shifts, in order to supply the ever-increasing demand for "the tire with the 5,000-mile guarantee."

Enter "The Vanderbilt."—B. S. von Rottweiler, until recently chief engineer and designer of the Fort Pitt Motor Mfg. Co., has organized a new concern to be known as the Mercedes Motor Mfg. Co., of New Kensington, Pa., and will bring out a new car, which will be called "The Vanderbilt." It will have a six-cylinder 75-horsepower engine and the price will be about $4,000.

Michelin Lowers Prices.—The Michelin Tire Company has just announced that the unexpected volume of business which has poured into their year-old American factory at Milltown, N. J., has enabled them to bring their production up to a point where their prices can be revised. The new list went into effect September 1 and consumers will derive a distinct benefit thereby.

Highway vs. Railway.—During the month of August 1,326 persons arrived at Hotel Mount Washington in automobiles, coming in 314 machines; arrivals by train were 630. Of course, most of the automobilists were transients only, but even at that no wonder the shrewd New England hotelkeepers are hastily building garages and buying in gasoline.

Fire Departments Up to Date.—The city of Frederick, Md., has an automobile fire engine and hose wagon in service and it has done some good work. The apparatus has three streams, with a pressure of from 125 to 150 pounds. The engine throws 450 to 550 gallons of water per minute. The hose wagon body carries 1,000 feet of fire hose.

News from Toledo.—B. O. Gamble, for several years the manager of the Toledo Motor Car Company, has just purchased the business and good will of that concern, which henceforth will be known as the Gamble Motor Car Company. Until a new building can be erected the business will be continued at the present location, 1115 Madison street.

Sailing to Savannah.—A large party of enthusiastic automobilists will sail for Savannah November 18 on the steam yacht "Idler," as the guests of Messrs. Fleming, Kull and Hamilton of the Gyroscope Automobile Company. On board the yacht will be the two Gyroscope cars which have been entered for the small car race.

Know Your Oil.—The Vacuum Oil Company of Rochester, N. Y., has brought out a booklet which will make it possible for the automobile owner to select the grade of oil best adapted to his car. It is claimed to contain the correct brand of Mobiloil for use in every car ever made.

The Driver and His Oil.—In a conversation with the representative of the A. W. Harris Oil Company just after the Lowell race on Labor Day, Lewis Strang, the winner, stated that he has used Harris oil in all of the three road-races which he has won—at Briarcliff, Savannah and Lowell.

Taxicabs for Baltimore.—The eighteen taxicahs to be operated in Baltimore by the Baltimore Taxicab Company are due to arrive this week. One of them was on hand last week and made a trial trip which proved very satisfactory. The cabs are the product of the E. R. Thomas Motor Company.

Oakland in the Glidden.—The Oakland Motor Car Company of Pontiac, Mich., is sending out a booklet telling the story of the Oakland entries in the Glidden Tour. It is attractively made up and is interesting reading. Copies will be mailed on request.

IN AND ABOUT THE AGENCIES.

Maxwell.—W. P. David has withdrawn from the Kelsey Motor Car Company, which represents the Maxwell car in Philadelphia, and W. C. Longstreth, the other partner, will continue the business alone at 204 North Broad street.

Chalmers-Detroit.—In the future the Chalmers-Detroit will be represented in Pittsburg by the Banker Brothers Company. Already a number of applications have been made for sub-agencies in Pennsylvania and West Virginia.

Chalmers-Detroit.—The Levy & Hipple Company, Chicago representatives of the Chalmers-Detroit, have completed plans for a three-story garage and retail establishment on Michigan avenue. The building will be white tile, 42x162 ft.

Elmore.—The Elmore Motor Company, of Los Angeles, Cal., has begun the erection of a new garage at 742 South Olive street, and expects to have it ready for occupancy October 1. It will be 80x167 feet, with a machine shop and ample storage room.

Stewart Speedometers.—The Stewart & Clark Mfg. Co., of Chicago, announces that it will shortly open a branch office in New York, which will carry in stock a large supply of Stewart speedometers and will have every facility for making prompt installations.

Premier.—Webb Jay, the well-known automobilist and former racing man, will handle the Premier in Chicago during the coming season. The Premier Century car, which has just completed its "100 miles a day for 100 days" schedule, is now in Chicago and is on exhibition at the Webb Jay Motor Car Company, in the Harvester Building, Michigan avenue and Harrison street.

PERSONAL TRADE MENTION.

C. E. Smith, who has been acting as traveling representative of the Fisk Tire Company, will in the future make Los Angeles, Cal., his headquarters, as assistant to C. O. Du Mars.

"Joe" Keir, formerly Renault and Fiat and Samson-Michelin tire agent in Philadelphia, has just closed with the Ajax-Grieb Rubber Company, of Trenton, N. J., to represent that concern's product in the Quaker City.

Russell E. Gilliam, formerly manager of the Empire Tire and Supply Company, has been appointed manager of the Newark, N. J., branch of the Empire Tire Company. He will be located at 264 Halsey street.

Fred D. Rathbun, formerly New England traveling representative of the Studebaker Company, has joined the forces of the Electric Vehicle Company. A large two-story garage will shortly be erected in Hartford, Conn., at Farmington avenue and Owen street, to handle gasoline and electric Columbias.

Charles B. Shanks, sales manager of the F. B. Stearns Company, will leave September 14 on a trip to the Pacific Coast, to establish a system of agencies from Vancouver and Seattle to Los Angeles. A branch house will be organized in California shortly if the trade comes up to expectations.

Two Leading Mitchell Exponents.
President William M. Lewis, at wheel, and Sales Manager James W. Gilson of the Mitchell Motor Car Company.

INFORMATION FOR AUTO USERS.

Willard Automobile Lighting Battery.—The strong and growing demand for electric light on automobiles makes this product especially acceptable, while the advent of the Tungsten lamp now makes it possible to electrically light a gasoline car very economically. The Willard Storage Battery Company of Cleveland, O., has for years manufactured the majority of the batteries used in this country for train lighting. The type E. L. B. battery, which has been designed for automobile work with Tungsten lamps is of the train lighting type, as the work required of the battery is practically identical with that required in train and Pullman car lighting. A number of very practical improvements are embodied in the construction of this battery. One is a chamber designed to receive the overflow of solution caused by expansion during charging. This construction also prevents any solution reaching the outside of the battery as a result of careless handling. The cells of the battery are placed in an acid-proof case, which is lined with lead. Each individual cell has its own cover, which is sealed into a frame at the top of the lead lining. Each cell also has its individual set of terminals. A band of hard rubber is vulcanized around each terminal to prevent the creeping of acid and consequent corrosion.

Willard Automatic Lighting Battery.

"Permanit" for Auto Tires.—A powder has recently been put on the market by Adolf Karl & Co., 239 Washington street, Newark, N. J., which they claim will not only prevent leakage of tires from punctures and blow-outs, but will also preserve the life of the rubber. "Permanit" not being a solvent in water will not form a paste or glue which might clog the valve, but on the contrary, when a puncture occurs the powder comes in contact with the outer air and causes a chemical reaction, whereby the injured part is healed. Because of the small amount necessary (only eight ounces to a tire), it can be used for high speed work.

"Permanit" is imported from Europe and is introduced for the first time in the United States. It is sold in cartons.

VOL. XIX NEW YORK—THURSDAY, SEPTEMBER 17, 1908—CHICAGO No. 12

THE AUTOMOBILE

Night Scene During Brighton Beach 24-hour Race—Coney Island is to Be Seen in the Distance.

AMERICANS ONE-TWO IN BRIGHTON BEACH "24"

TWO American Cars, both Loziers, one a "six," driven by Mulford and Cobe, the other a four-cylinder, piloted by Michener and Lynch, finished respectively first and second in the 24-hour race promoted by the Motor Racing Association at the Brighton Beach mile track, New York City, last Friday and Saturday. Both succeeded in surpassing the circular track record mileage of 1,079, made by Bernin and La Croix at the Morris Park 1.39 miles oval last year. The winner was 28 miles ahead of it and the second car beat it by 13 miles, with an average per hour respectively of 44.9 and 44.7 miles per hour.

A Fiat, a make that evolved victorious in the last 24-hour race held in the metropolitan district, was forced to accept the place of runner-up to the American pair. A Renault, the other European make represented, and, incidentally, the record holder, also went down in defeat, but through an accident in the second hour of the race, which put it out of the running altogether.

A Stearns, a Simplex and an Allen-Kingston followed in order in fairly close pursuit. Of the 11 starters there were practically 10 survivors, although one of these did not appear on the track during the last two hours of the contest.

The Winning Lozier.

The double victory of the Lozier was a popular one, not only by reason of its being an impressive American triumph, but from the fact that it came to the winning entrant, Harry A. Lozier, as a well-deserved reward for his persevering pluck in pursuing the racing game, which, save for a 24-hour victory at Philadelphia and an invariably creditable position among the leaders, had not been recompensed by any success.

That the meet was "outlaw" in that it was run without asking the sanction of the racing board of the national organization, has been too widely heralded to be unknown to any follower of the news of the racing game. Incidentally, there was a funny attempt on the part of Louis Strang to straddle or secure for himself possible immunity from punishment by making formal application, accompanied by a check, for a sanction from a member of the racing board. Needless to say the sanction was refused. It may also be worth while to note the report in circulation that the reason for the M. R. A. decision not to apply for a sanction was that a member of that body had been told by two A. A. A. racing board members that no sanction would be granted. This report was met by a posi-

Acme, Driven by Strang, Who Was Disappointing.

Michelin Tires Were Generously Used.

A Night View of the Garford Camp.

tive statement that the M. R. A. emissary either misunderstood or misquoted the reply given his question. This, however, was but one of the many rumors afloat to account for the action of of the M. R. A., most of which in all probability had nothing whatever to do with the stand the men interested decided to take.

The outcome of the meet showed that the public at large interests itself but little witb the sanction or anti-sanction controversy so long as it sees the prospect of good racing at the moment. There was a big, a very big, in fact, a record crowd in attendance on both Friday and Saturday nights. Tbe grandstand is credited with holding 3,500 and the field stand 2,800 people. Every seat in both was filled and there were probably several thousand more on the lawns in front. The gross receipts for the two afternoons and evenings are rumored to have approached $25,000 and the expenses to have been in the neighborbood of $14,000. With the horse-racing under a cloud and the season of the home-coming of the summer sojourners and tourists at hand, the racing and the excuse for a rendezvous were irresistible. The outpouring of automobiles was remarkable. Lawns and sheds were filled with them on both nights.

The men of the association are not inexperienced in the racing game, and they spared neither pains nor expense to insure a well-conducted meet. They were able to call to their assistance competent officials, with the result that the races were run off with satisfaction to the spectators and without any obtrusive complaint by the participants.

Tbe track owners had probibited oil being used. "Glutrin," a by-product of wood-pulp, was employed with highly satisfactory results in retarding the dust. Stereopticon bulletins, adding machines for the scorers and a strident electric horn for starting and warning were among the novelties introduced. The officials and newspaper men were well cared for over night, a dormitory and restaurant having been established in the clubhouse to offset the closing of the nearby Brighton Beach Hotel.

There were few men of prominence in the racing world on the official stand. Robert Lee Morrell was a referee, S. M. Butler and A. L. McMurtry were among the timers, Tom Moore essayed to masquerade as a "wag" pro tem. with the starter's flag, and Charley Earl was an announcer.

It had been heralded during Friday afternoon with much flourish of trumpets that President Roosevelt had consented to start the race by 'phone. Eight o'clock, the hour set for the start, approached and but two or three cars were at the tape. It came and no start. Perhaps Mr. Roosevelt had not finished his coffee, was the surmise of the expectant crowd. Not so. The Allen-Kingston camp had been given grace to repair a bent axle incurred in an afternoon sprint race. Half an hour later, however, the 11 contestants were lined up, six in the front and five in the back row. At 8:30 o'clock sharp Tom Moore pressed a button at the end of a long wire and the siren shrieked a shrill signal for the start. Whether President Roosevelt was at the other end of the judges' stand telephone wire the announcer failed to make known. With the press agent's proud paragraph in the late editions of the evening papers the incident perhaps may have been closed. There was an exciting scramble around the first turn and a mad scamper down the backstretch, from which Laurent evolved with the Stearns as leader of the first mile in 1:20. Mulford took the lead the next lap. The pace was fast and the changes were frequent. George Robertson, with whom a reckless gait is characteristic, was prominent in the sprinting and at 20 miles was in the lead with the Simplex in 25:26, and still in front at 25 miles in 31:40. Then Mulford took up the running with the Lozier "six," and led all the way past 50 miles—thirty in 37:51, thirty-five in 44:03, forty in 50;19, forty-five in 56:15, and 50 in 1:02:15, pursued in order by Michener in the Lozier "Four," and Parker in the Fiat.

Loziers Lead During First Hour.

Lozier No. 1 and No. 2 led in this order at the end of the first hour, with 48 miles to their credit. The Allen-Kingston, Renault, Stearns, and Fiat were tied two miles behind. The running the

first hour was four miles behind the De Dietrich's record, of 52 miles, made in the last Morris Park race.

The exciting all around racing, with gleaming headlights flashing around the turns, scurrying in a mask of electric flames down the homestretch, swinging recklessly around the bend, and speeding with red taillights marking their flight of the backstretch, got and kept the great crowd agoing with constant cheers for sharp brushes and encouraging cries to their favorites. This night racing is, indeed, an inspiring and weird spectacle, well calculated to arouse a thrill and a hurrah in even a cold-blooded cynical race follower. It was a splendid struggle this fight for the lead. It grew even hotter in the second hour. Lozier No. 1, Simplex and Allen-Kingston were having a neck-and-neck three-cornered fight. They finished the second hour even with 101 miles each and tied the record made by the Simplex at Morris Park. The excitement was continuous and the expectation of something going wrong with the contestants at any moment kept the spectators constantly on the *qui vive*.

Simplex, Robertson Driving, which at One Time Figured Dangerously as a Probable Winner.

Renault Meets with Disaster.

Before the second hour was little more than half way through the contingent of the crowd whose interest lay mainly in the possibilities of smashed cars and broken bones, got their money's worth in the first and only accident of the race. It put the Renault out of the race and its crew in the hospital. The S. P. O., a 16-horsepower taxicab chassis, with racing body, and another car, blocked the way of the Renault on the backstretch through being too far out from the pole. Paul Sartori, who was at the wheel of the Renault and has a reputation for recklessness, tried to cut through on the inside, struck the taxicab, and deflected his own car through the fence. His car was upset and completely wrecked. Sartori's arm was broken in two places, and his mechanic, Rene Gaurand, sustained severe scalp wounds. They were cared for in the hospital tent, later taken in an ambulance to the Coney Island emergency hospital, and the next day were removed to a New York hospital. It took nearly four hours to repair the S. P. O., which did not again take up the running until the sixth hour.

In the third hour the triple tie was broken by the Simplex and Allen-Kingston cutting away from Michener and having a battle royal of their own for the leadership. It was a hard fought scrap, in which Robertson finally prevailed and secured a three-mile lead over Rippigill. Michener chased the pair a mile in the rear. The Simplex was now tied with Lozier's 193 mile record for four hours at Morris Park.

In the fifth hour George Robertson set a whirlwind pace, covering 52 hours, scoring a new record, 245 miles against 237, the former figures. From this point on the leaders kept well ahead of the Morris Park figures. The Allen-Kingston had faltered and let Michener by with the Lozier, which, however, was six miles behind the Simplex. Robertson kept at it hammer and tongs the sixth hour. Michener dropped back into the ruck and the Allen-Kingston once more became the runner up. Mulford now began his fine work, which finally made the Lozier "four" a mere running mate for second place honors, and at the end of the hour was installed in third place.

Robertson Spoiled Simplex Chances.

In gaining and maintaining the lead Robertson had driven a reckless race utterly unmindful of any possibility of fuel exhaustion. His punishment came through the water giving out. A dry radiator and two cracked cylinders practically destroyed all chances the speedy Simplex might otherwise have had. The end of his long sprint came at 2.35 A. M., when the seventh hour had hardly begun. It took nearly three hours to put in new cylinders, and when Robertson appeared on the track again in the ninth hour he was far back in the ruck in eighth position.

All this time the triple winner of 1908, Louis Strang, had been lost so far back in the ruck that he was forgotten by the spectators, who had interest only for the heroes of the present. Strang had taken his seat in the Acme with practically not even a trial

In the Backstretch Occasionally the Cars Bunched and Made it Most Interesting.

"Outlaws" Morrell, Hollander, and Butler.

Tom Moore and Announcer Earl.

of the car. It was not until the fourth hour that the car was gotten into fair running shape. Barring the S. P. O. and the Garford the Acme was then at the tail end of the procession. It was in no shape, however, to show better than a 40-mile an hour average to the end of the race.

With the retirement of the Simplex with its cracked cylinders, the Allen-Kingston became the most conspicuous performer. For three hours it held a lead of from 6 to 12 miles over the Lozier "Six," scoring 50 miles in the eighth hour. Toward the close of the ninth hour, however, the leader met its Waterloo just as the Simplex had before it. A broken radiator, said to have been caused by a flying stone, put it out of the running long enough to ruin its chances. It took an hour to put in a new radiator, and when Rippigill again entered the race the Allen-Kingston found itself in fifth position.

Mulford Takes Lead and Holds It.

While the A.-K. was in camp Mulford grabbed the lead, which the Lozier "Six" held tenaciously to the end of the race. The Fiat flashed into second place and Michener held to third like a bull dog. The Fiat held stubbornly to second place from the tenth to the end of the fifteenth hour, when it lost it to Michener and never regained it thereafter, the trio running in the order of their finish to the end.

There was a halt called on the race at half past one o'clock on Saturday afternoon that the track might be watered, and two or three time killing events be run so that there might be a late finish to catch a Saturday-night crowd, the advertisements having promised that the end would not come until late in the evening.

At 3 o'clock the race was resumed. The mishaps of the Simplex and the Allen-Kingston had left them in fifth and sixth positions, respectively. Ralph de Palma had taken the wheel of the Allen-Kingston and George Robertson still pluckily stuck to the seat of the Simplex. The duel of these rival drivers and cars was the feature of the last hours of the race. Robertson, however, finally won out in the duel, made up his 50 miles, and won out by a couple of laps. In the eighteenth hour he scored 51, and in the nineteenth 54 miles, a total of 105 miles in two hours, which comes pretty close to being a track record.

The Stearns drivers, Laurent and Marquise, for the first time in the race gave the Stearns its full head and stalled off the Simplex and Allen-Kingston from overtaking them.

Those Stops for Unlighted Tail-lamps.

During Saturday evening Mulford was stopped frequently by the officials on account of the tail-lamps of Lozier No. 4 being out. It cost the car a lot of lost time. During Friday evening, by the way, the Fiat was stopped several times for the same reason. In fact, the bunch at one time made six circuits of the track while the Fiat was engaged in argument and relighting in front of the stand. Some official called to the timers to score the Fiat with the bunch. The next day W. E. Scarritt, then acting referee, heard of this and ordered six miles to be deducted from the Fiat's score.

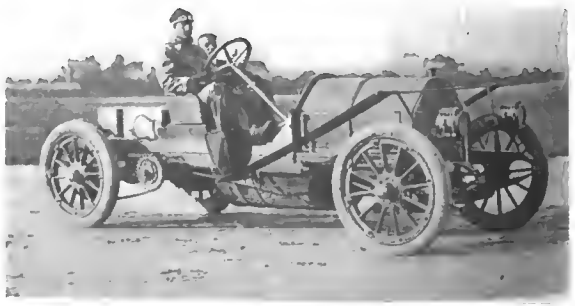
The Thomas "Forty," a six-cylinder stock car, which had been put in practically for a demonstration, made good with a steadily maintained average of about 40 miles an hour. Its troubles were few. The Garford had bad luck and was held up in camp at one time for 6½ hours at a single stretch.

The Loziers received an ovation at the finish, the crowd rushing on the track to greet the winner to the great danger of being run into by the cars, which Tom Moore was frantically striving to bring to a halt by waving a red lantern.

24-Hour Racers Mechanically Considered.

The result was a clean-cut victory for the Lozier in its securing both first and second places. Moreover, the winner was a six-cylinder car, the first ever entered in a race of this length. It was rated at 50-horsepower, with cylinders of 4 5-8 inch bore by 5 1-2 inches stroke. Mulford's four-cylinder car has cylinders 5 1-4 inches "square." Both motors follow the usual Lozier design; cylinders cast in pairs and covered with pearl gray enamel; valves on opposite sides; crankshaft forged from chrome-nickel steel, running on ball bearings. Both have multiple disc

Re-start on Saturday After Repairing Track.



Marquise and the Stearns Performer.

clutches and four-speed selective change-gears with direct drive on third speed. Drive to the rear axle is through a shaft with a single universal joint, housed in a tube which acts as a torsion rod. All wheels are 36 inch with 4-inch front and 4 1-2-inch rear tires, of Continental make. The wheelbase of the six-cylinder car is 131 inches and of the four-cylinder 124 inches. One detail which showed the careful preparation of the cars for the race was the arrangement of the taillights, which were enclosed in the rear part of the body work, with only the red bull's-eyes showing. Bosch was the magneto used.

The Fiat driven by Capra and Parker took third place, showing good speed and losing little time in the paddock. Its motor develops 60 horsepower, with cylinders 140 by 135 millimeters (5.52 by 5.32 inches) and, of course, cast in pairs with opposite valves. It was the only car in the race using low-tension ignition, the current being generated by a Bosch magneto. The change-gear gives four speeds, operated selectively, and drive is through side chains.

Laurent's Stearns No. 4 was another consistent performer and was always well up in the list. Its four-cylinder motor has cylinders cast in pairs, 5 3-8 by 5 7-8 inches, with both inlet and exhaust valves on the left side actuated from one camshaft. One notable feature is the double-jet carbureter, which accounts for the otherwise rather ambiguous rating of 30-60 horsepower. Stearns also departs from established standards in the use of an expanding band clutch. Gear change is by the usual four-speed selective system and drive through side chains. The wheels are shod with 36x4 and 36x4 1-2 inch Continental tires.

The Simplex was admittedly the fastest car on the course, and was also the highest powered, its four cylinders being 5 3-4 inches "square." They are cast in pairs with opposite valves, and drive is through a four-speed selective gear and double chains. The wheelbase is 126 inches.

Allen-Kingston was of lower power than any of the cars which finished ahead of it, but managed to hold its own fairly well. The dimensions of its cylinders are 5 by 5 1-2 inches, and the design follows accepted standards. The clutch, however, is rather unusual, consisting of only five discs, alternate steel and bronze. Drive is by shaft to the live, floating rear axle.

Strang's Acme was a stripped six-cylinder roadster, with cylinders cast separately; ignition by Eisemann magneto and batteries, with two sets of plugs. Another six-cylinder contestant was Montague Roberts' Thomas. The S. P. O. is a newcomer to the American trade, and there was much uncertainty as to its origin. It is made by the French Société de Petit Outillage, and is only of 16 horsepower. The Garford 40, which suffered from various troubles, and Sartori's unlucky Renault are both stock cars of familiar designs.

Another Race Will Be Held.

Following the big race came a challenge and an acceptance and with them the chance of a sweepstake being embodied in the next 24-hour contest, which is announced for October 2-3. Paul La Croix was naturally a bit crestfallen at the Renault being put out of the race by an accident so early as to cut off the car's chances of repeating or bettering the record performance of this make at Morris Park. He accordingly issued a challenge to any competitor in a future race to put up $1,000 against his entry. Charles Singer, entrant of the Simplex, which held the lead for several hours in record time early in the contest, was quick to respond with an acceptance and suggestion that the third and fourth cars be also invited to compete in the sweepstakes.

Short Events Were Mediocre.

As usual a program of sprints was run the afternoon prior to the start of the big race, but they did not pan out over well. There were few entries and the waits between were tediously prolonged.

A View of the Infield from the Grand Stand.

PARKWAY TO BE OPENED WITH SWEEPSTAKES

INSTEAD of the elimination trials for the Vanderbilt Cup which were planned to be held on Long Island on October 10 next, the Vanderbilt Cup Commission has decided to substitute a fitting celebration to mark the opening of the Long Island Motor Parkway. The event to be held will be known as the Long Island Motor Parkway Sweepstakes, and owing to the unusual and unequalled facilities offered by the course, the race will be marked by features hitherto impossible in connection with automobile speed events. Cars of every class, selling from $1,000 up will be eligible to compete, and unlike any previous event of the kind, they will all be started at once. Owing to its novelty and the fact that makers are anxious to try out their 1909 models in competition with those of their competitors, it is thought that there will be fully 75 entries.

Joseph Tracy in His Locomobile, Making 95 Miles an Hour on the Parkway.

Another unusual feature of the event is to be found in the fact that the daylight start of bygone days will be abolished, the cars not being sent away from the line until 9 a. m. The 25-mile circuit laid out for the Vanderbilt cup race will be employed, the larger cars making ten laps, or a distance of 250 miles, while the smaller machines will be required to go from four to eight laps according to their selling prices. It is easy to realize the spectacular possibilities of an event in which such a large number of cars will be running round a 25-mile circuit, and there certainly should be no long waits at the grand stand, while close brushes past it will doubtless be frequent. In fact the excitement there should be continuous, and quite in contrast with former events, as up to this time it has been impossible to start a large number of cars at once.

On the date in question they will be sent away in lots, or with an interval of 30 seconds between, and as the 11-mile stretch of cement parkway offers unrivalled speed facilities, the competing drivers will be able to get out of one another's way soon after leaving the stand. The grand finish will be for the high-powered cars only, as they will go the entire distance of 250 miles, making ten laps of the circuit. Cars selling under $2,000 will only be required to go four laps, while those listing between $2,000 and $3,000 will have to make eight laps; those selling above $3,000 will have a chance to be in at the finale of the day.

Although the entrant must furnish evidence that the machine entered is of a type to be produced during 1909, or one that has been produced in quantities during the past season, the Cup Commission has offered the manufacturer more liberal conditions than have ever been granted in any stock touring car event. Touring cars, as well as all other machines, may be completely stripped and put into racing form, even including the use of special racing gear ratios, the removal of guards, mufflers and other impedimenta to a racing car being permitted. Where mufflers are carried, the only restriction concerning them is that they shall not be pointed toward the ground.

The grand stand, which is being built for the Vanderbilt cup race, to be held over the same course on October 24, will be completed in time for the Motor Parkway Sweepstakes and the Long Island Railroad and trolley special service will be running in full force, the same as on the day of the big race two weeks later. The cup circuit is now in practically complete condition, all the bridges crossing intersecting highways being up, while the oil for the State and county roads connecting the two ends of the 11-mile stretch of the cement parkway has now been received and will be utilized to make this part of the course dustless. An elaborate telephone system for signaling the timing and reporting the positions of the cars on the various parts of the course has been installed. Boxes and seats in the grand stand are now on sale and may be had from Jefferson De Mont Thompson, chairman of the Vanderbilt Cup Commission, at the headquarters of the American Automobile Association, 437 Fifth Avenue, New York.

Entry blanks are now out for the Motor Parkway Sweepstakes, the preliminary announcement of the various classes, for which $5,000 in prizes are offered, being as follows:

Class No. 1: Motor Parkway Sweepstakes.—For cars selling above $4,000. Entry fee, $150 for each car. Cash or plate prize to the winner of $1,000. Distance, ten laps of the circuit.

Class No. 2: Meadow Brook Sweepstakes.—For cars selling over $3,000 to $4,000. Entry fee, $125 for each car. Distance, ten laps of the circuit. Cash or plate prize of $1,000 to the winner.

Class No. 3: Garden City Sweepstakes.—For cars selling from $2,001 to $3,000. Entry fee, $100 for each car. Distance, three laps of the cup circuit. Cash or plate prize of $1,000 to the winner.

Class No. 4: Jericho Sweepstakes.—For cars from $1,001 to $2,000. Entry fee, $75 for each car. Distance, six laps of the cup circuit. Cash or plate prize of $1,000 to the winner.

Class No. 5: Nassau Sweepstakes.—For cars selling for $1,000 or under. Entry fee, $50 for each car. Distance, four laps of the cup course. Cash or plate prize of $1,000 to the winner.

WHY FAIRMOUNT SANCTION WAS GRANTED.

PHILADELPHIA, Sept. 14.—The 200-mile "Founders' Week Stock Chassis Road Race" is assured. It will be pulled off Saturday, Oct. 10, between the hours of 6 and 11 A. M., over a 7.8-mile course in Fairmount Park. The Park Commissioners have coupled the permit with a number of conditions but all of them are reasonable and will be gladly complied with by the Quaker City Motor Club. Besides granting the permit for the actual race, the commission adopted a resolution that, "under the conditions of the request, automobilists who propose entering the race shall be permitted to practice daily over the route for one week prior to the race between 7 A. M. and noon every day."

A fraction over 25 circuits of the 7.8-mile course will be necessary to complete the 200 miles, but it is likely that the committee will make it an even 25 times around—195 miles.

In the argument that preceded the final granting of the permit, Commissioner James Pollock made the somewhat surprising statement that during the past year the records showed that more automobiles had entered the park than horse-drawn pleasure vehicles. "We must, therefore, give consideration to the motor car," he said.

At the Comfortable Base of Wilbraham Mountain. Start of the Springfield Club's Mile Climb.

KNOX WINS MOST HONORS IN WILBRAHAM CLIMB

SPRINGFIELD, MASS., Sept. 11.—Springfield, home of the Knox and Stevens-Duryea, famed in days gone by as the arena of the world's biggest bicycle meets and the scene of the most famous exploits awheel of its great cycle champion, George Hendee, now a leader in another branch of the motor vehicle industry, well sustained to-day the sporting reputation of the old town by the successful promotion of one of the best hill climbs and most difficult up-grade tests yet credited to New England.

In Wilbraham Hill the Automobile Club of Springfield has a proposition well worthy of attack by the most ambitious hill-climbers. It is a sheer ascent of a mile, that goes straight up the side of the mountain with grades varying from 6 to 25 per cent. They made the most of it by good management and setting forth a well conceived program that gave golden opportunities to all classes of cars were they segregated by piston area or by price.

At the lowest estimate 7,000 spectators gathered to see the climb. No less than 800 automobiles lined the road and at that scores of machines were unable to obtain parking spaces.

Charles Basle, who won record-breaking fame at Ormond and on several circular tracks and is to be a pilot in the coming Vanderbilt Cup race, carried off the time honors of the day in the 48-50 Knox "sportabout" he is to drive in the Long Island classic. Arousing the wildest enthusiasm over his skill and daring, Basle made the steep mile ascent in 1:08, a rate of but a fraction under 53 miles an hour.

There was but one driver and one car at the climb that gave any promise of equaling or beating this time, and that was the unfortunate Robinson with the Stevens-Duryea "Big Six." While taking the hill at a terrific gait in an attempt to lower Basle's record his car skidded three times across the course at the first parking ground and struck a boulder which shattered the right rear wheel. The car turned somersaults and Robinson was thrown 50 feet to the roadside below. Fortunately he escaped with no more injury than a broken leg and painful bruises. After that Basle's time was never in danger.

The accident had a notable effect on risks taken by the other contestants, resulting in comparatively slow time made in the following events. Baldwin in his Stanley steamer made an unsuccessful attempt to lower Basle's time. Like the other drivers, especially of the lighter cars, however, he recognized the danger of the abrupt turns and grades. In his trial he made the climb without full steam, his momentum being great enough to carry him from the foot well up the hill. Then he opened his throttle again for a final dash for the tape. His time was 1:11 2-5, which placed him in the fastest class.

The fastest time of all motor vehicles was made by Stanley Kellogg on a 7-horsepower Indian motorcycle, 1:03 4-5. In the event for gasoline cars selling for $4,000 and over, the Stevens Big Six established a mark of 1:10 1-5, which stood for some time. The climb for cars of from 24.1 to 40 horsepower inclusive was the closest and most interesting contest of the day. Hancock with a Stevens Little Six got away with first place rather easily in 1:22 3-5, but Knox, Buick and Chalmers-Detroit had a hot fight for the next position. They finished in the order named, but with only a fifth of a second between each one.

In the class for cars with piston area of 90 and over, Robinson and his Big Six covered the course in 1:09 4-5. When he came over the level stretch after leaving the first grade he was going over 70 miles an hour, and as he turned the course on the 23 per cent. grade his car slewed across the road and the rear wheel cut into the bank, throwing dirt and stones 30 feet into the air. Yet he held to the road and received a great ovation at the finish.

Half Way Up the Mountain There Is a Level Stretch, and Here Many Onlookers Naturally Congregated.

Basle and Knox Fastest Performer.

Bourque and the Second Knox Winner.

Enthusiasm was at a high pitch now, and when in the gasoline free-for-all Basle whirled up the grade and around the turn on two wheels in 1:08, bedlam broke loose and for fully fifteen minutes the crowd yelled and cheered. Bourque, in a 38-40-horsepower Knox, added to the tumult by another wild dash up the hill in 1:09 4-5. Still Robinson was looked to for faster time. Hopes were dashed to the earth and joy changed to sympathy when his run was ended at the first quarter-mile by the accident that crippled him and ruined his car.

Borque won second place in the "record of the hill" climb by negotiating the course in 1:09 3-5. Basle went over the course again in 1:12 flat, not attempting to beat his former time. Baldwin, in the Stanley, cut this down three-fifths of a second. As he came up the roughness of the course jolted him time and time again from his seat. His car bounded rather than rolled, and faster time would have ditched him without much doubt.

The club spent considerable money in preparing the hill for the contest, but at that it was a little too rough for great speed. So great was the success of the meet from a popular standpoint, however, that it will probably be repeated next year, and in that case the club will spare no effort to get the road in the best possible condition. The management could not have been improved on and the club committees deserve the highest credit for their work.

WHY THE LONG STROKE FOR MOTORS?

By S. F. EDGE.

IN view of the present great interest that is being taken in the very incomplete R. A. C. formula for rating motors, it seems to me it is worth consideration why competitors in racing motor car events have started developing the long-stroke engine. Ordinarily commercial engines have got down to a reasonable proportion between stroke and bore, in fact, I think every up-to-date motor car maker was considering quietness, smoothness of running and economy in tires and mechanism almost before everything. Then the Royal Automobile Club of England, and the Automobile Club of France both suddenly started rating engines for competitive purposes by the size of the cylinders only. The result of this was that the far-seeing manufacturers, who understood their business, at once realized that these two clubs had brought out a formula which placed no restriction on stroke. Experiments were at once carried out, and it was then found that increasing the length of the stroke was almost as good as increasing the bore.

In developing the formula, diameter of cylinders squared multiplied by number of cylinders, divided by 2.5, the compilers of the formula no doubt assumed that long stroke motors would be run at slow speed, or in other words, the speed would be inversely proportioned to the length of stroke, and that the limit to speed and stroke (that is to say, piston speed), would be the strength of the moving parts.

This, however, is not the limiting factor, for it is possible to make these parts of material of such excellent quality, which, correctly disposed within the parts, ensures that their actual strength is much greater than the stress which they are called upon to withstand, with the motor running at maximum speed. There are two chief factors which limit the engine speed:

(1) The actual rubbing velocity of the pistons within the cylinders.

(2) The rapidity of actuation of the valves, and the speed with which the gases can be taken in and expelled from the cylinders.

With the piston speeds at present in vogue, even in races where they are maintained at the highest limit, it is possible to get over the piston lubrication difficulty by judicial lubrication at the expense of a smoky exhaust. The second factor, therefore, is the chief limitation so far as the engine speed of racing motors is concerned.

There are other factors which limit the speed, such as the rate of ignition, inflammation, and combustion of the gases, the speed of the ignition apparatus, etc., but the effect of these things is not so great as those above-mentioned. The rapidity of actuation of the valves does not depend upon the length of stroke of the motor, but since the speeds of motors of different strokes but of the same bore, have been found to be practically the same, it follows that the powers are approximately proportional to the length of the strokes. Racing motors which have a limited piston area, and from which it is desirable to obtain the maximum power, have, therefore, to be fitted with excessively long strokes.

The formula rates a motor with a short stroke the same as one with a long stroke, provided the piston area is the same in both, and although the performance of the long stroke motor, so far as actual H. P. is concerned, is undoubtedly better than the one with the short stroke, yet by rating their performances should be similar. Actual experience teaches that the formula does not give a true rating, and if the rating is to be a measure of the H. P. developed, the length of stroke must be introduced into the formula. It seems so very simple to have a formula which takes into account stroke, and I do think that whatever formula is selected it should be reasonably near the actual brake horsepower that the particular engine being calculated should give, if it was a modern, efficient, commercial engine.

The calculation of the power of an engine must necessarily be based upon the force behind the piston and the speed at which it moves, whatever means are taken to express this; that is to say, we have three factors which it is necessary to ascertain before the power of an engine can be calculated, namely, the area of the piston, the pressure per square inch to which this area is subjected, and the number of feet through which the piston moves in one minute. It is obvious that it is only on the first of these three that definite limits can be put, and that any limits selected for the other two figures must be purely arbitrary and liable to require revision from time to time, the only alternative being to measure them on each individual engine. It seems to me that this would be too big a task to be undertaken for general purposes, and that the simplest way is to select what is known to be a fairly high average in each case. This would mean that designers would be stimulated to raise these figures to the greatest possible extent.

If we start with the usual horse power formula $\frac{P \times A \times S}{33000}$

where P = mean effective pressure in lbs. per square inch.

$A = 11$ times $\frac{D^2}{4}$ = area of piston.

$S = L + N + 2$ = piston speed in feet per minute where

L = length of stroke in feet and

N = number of revolutions per minute

the simplest way is to boil it down by obtaining a constant from all the known or arbitrarily selected figures by which the variables can be multiplied or divided. To illustrate this, I assume mean effective pressure of say 80 lbs. per square inch, and a piston speed of say 1400 feet per minute; we then get the following formula from the above:

$$\frac{P \times L \times N \times 2 \times 11 \times D^2}{4 \times 4 \times 33000}$$

Assuming a square engine, say 5" x 5" a piston speed of 1400 feet per minute would involve a speed of 1680 revolutions per minute, the formula therefore becomes:

$$\frac{80 \times L \times 1680 \times 11 \times D^2}{2 \times 4 \times 33000} = L \times D^2 \times 1.6 \text{ the result}$$

being the horse power of one cylinder. Assuming a 5" x 5" engine, this formula gives 16.5 H. P. per cylinder, a figure quite easy to obtain, but assuming the stroke increased to 7" the formula gives 23 H. P. On the other hand, for a 4" stroke 13.3 H. P. is obtained. The difference in horse power between the extremes in this formula seems to me rather great, and possibly would tend to too much restrict the permissible variation in stroke. The way to correct this would be to use the square root of the stroke as a multiplier and suitably reduce the constant; this gives us the following formula:

$$2 L \times D^2 \times 1 = \text{H. P.}$$

This gives us for a 4" stroke cylinder 14.25 H.P. for a 5" 16-H.P., for a 6" 17.5-H.P., and for a 7" 18.9-H.P. These proportions are in accordance with practice. At the same time, the variation between the extremes should be sufficient to restrain designers from adopting extremely long or extremely short strokes. The reasons for wishing to handicap the long-stroke motors lie in the motors themselves. They present many difficulties, and are not so well adapted for driving motor cars as are engines with shorter strokes.

The chief objection to excessively long strokes are: (1) Size of engine, (2) vibration, (3) weight of engine, (4) noise from engine, (5) lack of flexibility, (6) difficulty of starting, (7) danger from pre-ignition, (8) necessity for stronger shafts, etc., in transmission gear, (9) increased wear and tear on tires.

(1) **Size of Engine.**—Long stroke engines must have proportionately long connecting rods, and on this account the distance from the center of the crank to the top of the cylinders is considerable, and the oil base must also be very deep to allow for

the swing of the crank. In order to get sufficient clearance it is necessary to carry the crankshaft higher in the frame, which necessitates raising the gearbox, clutch and other parts. This raises the center of gravity of the car considerably and thus it is more easily overturned and skids more readily. The engine, being built very high, necessitates a higher dashboard and bonnet, and the seats must therefore be raised to give a clear view, which also raises the center of gravity of the car. The larger crankcase occupies space usually taken up by the magneto, water pump, etc., and these have to be placed in more restricted positions, where they are less accessible.

(2) **Vibration.**—However well balanced an engine may be, there is always a slight amount of vibration. This need not be very much with short stroke motors, but with excessively long strokes it becomes very serious. It is due to the inertia forces of the reciprocating parts causing the crankcase and crankshafts to distort and "whip," and in addition to the discomfort of riding in the car there is the grave danger of the crankshaft breaking through fatigue due to the vibration.

(3) **Weight of Engine.**—Excessively long-stroke motors are exceedingly heavy. They are very high, the crankcases are very large to accommodate the swing of the crank, the valves must be large, so as to allow the large quantity of gas easy ingress and egress, and the valve ports, pipes, cylinder heads, etc., must be in proportion. The reciprocating parts must be made heavier than those for equal bore short-stroke motors. It is also necessary to employ a heavier design of crankcase and oil base, in order to make these strong enough to withstand the stresses due to high speeds combined with long strokes, and in order to withstand the vibration the crankshafts must be made considerably larger in diameter. These conditions result in an engine which is considerably heavier than an engine of equal power with a shorter stroke and greater bore.

(4) **Noise from Engine.**—This is due to vibration and valve actuation, and is so well known that nothing need be said about it.

(5) **Lack of Flexibility.**—The long-stroke motor is not flexible. The compressions require so much effort to overcome them that the necessary weight of flywheel is prohibited.

(6) **Difficulty of Starting.**—In order to turn the long-stroke engine by hand, it is necessary to have a half-compression gear even for engines having a comparatively small piston area.

(7) **Danger from Pre-ignition.**—This is considerable, for although the pressure in the cylinder due to the pre-ignition may be no higher than that in a short-stroke motor under the same conditions, yet the crank arm being longer and the connecting rod being in a more oblique direction, the actual stresses induced in all parts are considerably higher.

(8) **Necessity for Stronger Shafts, etc., in the Transmission.**—Owing to the uneven torque due to the long stroke, and the wide variation between maximum, average and minimum torque, it becomes necessary to design the shafts to suit the maximum stress to which they will be subjected. Increasing the size of these shafts also adds to the weight of the chassis.

(9) **Increased Wear and Tear on Tires.**—This is due to the uneven torque of the long-stroke motors, the increased weight of the motor and chassis, and the greater amount of skidding between the tires and the road.

I think you will agree with me that the above is a good case against the abnormally long-stroke motor, and that it has no reason for existence except for the purpose of getting the better of a formula which is inadequate for present-day conditions of motor car engine manufacturing. The ordinary purchaser can always reckon that his tire bill will go up in accordance with the increased length of stroke.

Of course, no doubt it will be argued by those interested in powerful four-cylinder engines why a long stroke is desirable, and I think the reason for those so interested saying this is simply that, area for area, a six-cylinder motor can be run to develop greater horsepower than a four-cylinder with a short stroke, so that for powerful cars six-cylinder engine gives you the advantage over the four-cylinder, as with the same size engine one can get more horsepower, and as this horsepower is divided into six units instead of four, tremendous saving on one's tire bill and wear and tear on the mechanism is achieved.

I am sorry, in a way, when trying to obtain a really good formula for motor car competitions, that it brings out rather markedly the advantages of Mr. Napier's six-cylinder principle for motor cars, and this, no doubt, will have the effect of raising a lot of opposition of a commercial, but not scientific character. It remains to be seen what new objections will be raised.

AN ARGUMENT FOR THE LONG STROKE IN MOTORS

THE long stroke motor is distinctly advantageous, concludes Gerald Lavergne, after a close study in *Omnia* of the results obtained by all the most important European constructors. Its disadvantages, which may be summed up as increased area of the motor, increase in weight, increased losses in cooling (which can be diminished by the increase of the linear speed of the piston) are not to be compared with such advantages as the more homogeneous formation of the charge, the more complete accomplishment of the various cycles, and especially the better utilization of the explosive stroke, decreased wear, higher compression and the advantages which arise from it. Experience has abundantly proved the advantage of a long stroke. The question is what figures to adopt. Though it would be presumptuous at the present time to definitely fix the ratio of bore to stroke, certain modifications can be made with advantage to the figures generally adopted. The ratio of maximum pressure developed by the explosion to the average pressure is usually 15; there would be an advantage in diminishing this by reducing the piston area and increasing the stroke.

The proportions of the explosive mixture are generally 13.5 parts of air to one part of gasoline; the proportion might be increased to 15 parts of air. Thus, without fear of pre-ignition, the compression could be increased to 6 kilograms per square centimeter (85.3 pounds per square inch), or to 5 kilograms (71 pounds) for touring cars, in order to facilitate speeding up of the engine.

The linear speed of the piston, which, as shown by the table of leading French motors, model 1906, oscillated between 141 and 314 inches, increased to 472 inches per second in the single-cylinder Delage, which won the Grand Prix des Voiturettes. The speed could generally be carried to 310 to 390 inches a second.

Finally the ratio of stroke to bore, as shown in the table, of all the models built by over thirty leading French constructors has risen from 1.01 to 1.10 in 1906, to 1.11 to 1.20 in 1908, and has been increased to 2 in the single-cylinder Sizaire-Naudin racer, which competed in the Grand Prix des Voiturettes. We believe this ratio could advantageously be carried to 1.40 for touring cars or to 1.60 for small bore engines.

The following table shows the tendency of French and foreign constructors in the matter of ratio of stroke to bore, the models of 1906 and 1908 being compared from data supplied by the constructors.

	French cars 1906 Up to 6.2 ins. bore	French cars 1908	Foreign cars 1908
Number of builders	77	32	18
Number of motors	77	126	57
Percentage of short motors	10	25.5	7
Percentage of square motors	6	10.3	3.5
Percentage of long motors	84	84.2	89.5
Maximum ratio of stroke to bore	1.50	1.60	1.40
Percentage of ratios for long motors: above 1.30	16	21.04	6
from 1.30 to 1.21	9	17.4	26
from 1.20 to 1.11	28	50.9	40
from 1.10 to 1.01	30	10.3	28

SUGGESTIONS FOR THE MAN WHO DRIVES HIS CAR

By THOS. J. FAY, E. E., President Society of Automobile Engineers.

THE first six cases of this table appeared in September 10 issue. All dealt with the failure of the motor to operate, either on account of faulty assembling or of defects in the carbureter or battery ignition. In the following cases are considered further reasons for the failure of the motor to operate; reasons for noisy running; faults in the clutch and transmission, and finally, causes for excessive cost of maintenance. The same course of procedure is followed; the known quantities or symptoms are first verified, and then, one by one, the unknown quantities are eliminated until the cause of the trouble appears.

CASE NO. 7—MOTOR WILL NOT OPERATE.

Known Quantities (involving the magneto).

(*a*) Compression is normal.
(*b*) Carbureter in normal state.
(*c*) Timer in good order (battery ignition side).
(*d*) Battery ignition wiring in good order.
(*e*) Battery in good order.
(*f*) Spark coil in good order.
(*g*) Spark at the spark plugs.
(*h*) Magneto system will not work.

Unknown Quantities (involving the magneto.)

(*a*) Defective spark plug?
(*b*) Soot on spark plugs?
(*c*) Magneto out of time?
(*d*) Secondary wiring leaks with compression (not shown in air)?

CASE NO. 8—MOTOR WILL NOT OPERATE.

Known Quantities (involving the magneto).

(*a*) Compression is normal.
(*b*) Carbureter in normal state.
(*c*) Timer in good order (battery side).
(*f*) Battery ignition wiring in good order.
(*g*) Battery in good order.
(*h*) Spark coil in good order.
(*i*) Magneto system will not work.
(*j*) No spark at the spark plugs.

Unknown Quantities (involving the magneto).

(*a*) Secondary wiring open circuit?
(*b*) Secondary wiring short circuited?
(*c*) Distributer contacts not bearing?
(*d*) Short circuited distributer?
(*e*) Primary contacts in distributer worn down and not making contact?
(*f*) Wiring wrongly connected?
(*g*) Magneto wiring (armature) short circuited?
(*h*) Permanent magnets demagnetized?
(*i*) Driving mechanism adrift?
(*j*) Condenser defective?
(*k*) Ground connection open circuited?
(*l*) General leak due to oil and dirt?

CASE NO. 10—MOTOR WILL NOT OPERATE.

Known Quantities (involving the cranking.)

(*a*) Compression is normal.
(*b*) Carbureter in normal state.
(*c*) Ignition systems in good order.
(*d*) Gasoline supply available.
(*e*) Motor "back kicks."

Unknown Quantities (involving the cranking).

(*a*) Hot motor?
(*b*) Spark advanced?
(*c*) Lost motion in spark control system?
(*d*) Combustion chamber incrustation?
(*e*) Detonating ingredients in gasoline?
(*f*) High compression and slow cranking?
(*g*) Timer adrift?
(*h*) Broken tooth in half-time gear?
(*i*) Camshaft out of true relation?

CASE NO. 10—MOTOR RUNS NORMALLY.

Known Quantities (involving the clutch).

(*a*) The clutch holds.
(*b*) Impediment to speed changing lever.

Unknown Quantities (involving the clutch).

(*a*) Kink in the sliding gear shaft?
(*b*) Bunged-up gear teeth?
(*c*) Linkage adrift?
(*d*) Sticky bearing?
(*e*) Broken lever?
(*f*) Broken or sprung gear case?
(*g*) Congealed oil in sliding mechanism?
(*h*) Lost keys?
(*i*) Dry surfaces (no oil)?

CASE NO. 11—MOTOR RUNS NORMALLY.

Known Quantities (involving the gears).

(*a*) Change speed lever is free.
(*b*) Clutch movement is free.
(*c*) Clutch holds.

Unknown Quantities (involving the gears).

(*a*) Key out of a gear?
(*b*) Stripped gear?
(*c*) Shaft spread?
(*d*) Shaft twisted off? (Planetary especially.)
(*e*) Gears slide by?
(*f*) Broken linkage?

CASE NO. 12—MOTOR RUNS NORMALLY.

Known Quantities (involving the clutch).

(*a*) The change speed lever is free.
(*b*) Clutch movement is free.
(*c*) The clutch does not hold.

Unknown Quantities (involving the clutch).

(*a*) The leather facing is oily?
(*b*) The leather facing is charred?
(*c*) The leather is hard and does not press uniformly?
(*d*) The clutch spring is weak?
(*e*) The clutch is out of alignment?
(*f*) The sliding bearings are dry?
(*g*) The clutch is worn and will not advance to a bearing?
(*h*) Clutch band broken?
(*i*) Clutch lever bent?
(*j*) Dog bent or worn?
(*k*) Toggle with excessive lost motion?
(*l*) Foot lever strikes deck?
(*m*) Take-up all in?
(*n*) Disc facings worn out?
(*o*) Discs adrift from keys?
(*p*) Cork inserts worn below surfaces?
(*q*) Clutch cone worn?
(*r*) Wedge cut away?
(*s*) Screw worn?
(*t*) Excessive oil?
(*u*) Dirt impediment?

(v) Take-up backs off?
(w) Chassis lateral backs away from strain?
(x) Spiral band too long?
(y) Affected by centrifugal force?
(z) Brakes either on or too tightly adjusted?

CASE NO. 13—MOTOR RUNS NORMALLY.

Known Quantities (involving the clutch).

(a) The change speed lever is free.
(b) The clutch sticks.

Unknown Quantities (involving the clutch).

(a) "Frozen" shaft?
(b) Lack of lubrication?
(c) Congealed oil (cold weather)?
(d) Sag in chassis frame?
(e) Shaft twisted?
(f) Spring broken?
(g) Disc deformed?
(h) Broken motor or gearcase arm?
(i) Deformed driving arm?
(j) Thickened leather or other facings of disc clutches?
(k) Damage due to thrust?
(l) Bent crankshaft?
(m) Bent planetary shaft?
(n) Deformed linkages?
(o) Stuck "dogs"?
(p) Worn screw?
(q) Tight spiral band?
(r) Dent in housing?
(s) Shifted motor?
(t) Shifted transmission?
(u) Dirt (foreign substances)?
(v) Bent foot pedal?
(w) Insecure locking devices?
(x) Centrifugal force?
(y) Torn leather facing of cone clutch?
(z) Worn faces changing the distance of travel?

CASE NO. 14—MOTOR RUNS NOISY.

Known Quantities (involving the motor).

(a) Compression moderate.
(b) Runs bot on retarded spark.
(c) Knocks badly on long grade.

Unknown Quantities (involving the motor).

(a) Carbureter delivers rich mixture.
(b) Excessive lubrication.
(c) Poor selection of lubricant.
(d) Cooling system inefficient.
(e) Carbon deposit in cylinders.

CASE NO. 15—MOTOR RUNS NOISY.

Known Quantities (involving the motor).

(a) Compression moderate.
(b) Lubrication good.
(c) Cooling system efficient.
(d) Carbureter working correctly.
(e) Timing correct.
(f) Knocks at the higher speed range.

Unknown Quantities (involving the motor).

(a) Pistons a loose fit?
(b) Pistons worn?
(c) Piston pin bearing slack?
(d) Crank pin bearings slack?
(e) Main bearings slack?
(f) Crankshaft bent, imparting side shake to connecting rod?
(g) Crankshaft end motion?
(h) Valve clatter due to strong springs?
(i) Valve clatter due to wear in guides?
(j) Loose valve lifts or tappets?
(k) Loose half-time gears?
(l) Camshaft twisted?
(m) Timing deranged?
(n) Flywheel loose on crankshaft?
(o) Clutch scraping?
(p) Connecting rod striking crankcase?
(q) Stray bolt or nut adrift in crankcase?
(r) Wheezing of air or mixture through open seams?
(s) Exhaust manifold open at joints or elsewhere?
(t) Dry bearings due to lack of oil?
(u) Cylinder loose?
(v) Fan striking cooler (common)?
(w) Lost motion in timer?
(x) Magneto armature striking?
(y) Flywheel scraping on pan?
(z) Water pump worn?

CASE NO. 16—MOTOR RUNS NORMALLY.*

Known Quantities (involving noise).

(a) Car standing, motor runs noiselessly.
(b) Car running, motor runs noiselessly.
(c) Car runs noiselessly, direct on the high.
(d) Excessive noise on low gears.

Unknown Quantities (involving noise).

(a) Gears not set to the pitch line?
(b) Gears not properly shaped?
(c) Pitch line velocity of gears too high?
(d) Gear teeth bunged up?
(e) Gearshafts loose in bearings?
(f) Oil leaked out (planetary)?
(g) Transmission case full of grit?
(h) Shaft end motion (thrust bearing not adjusted)?

CASE NO. 17—MOTOR RUNS NORMALLY.

Known Quantities (involving noise).

(a) Car standing still, motor runs noiselessly.
(b) Car in motion, motor runs noiselessly.
(c) Car makes noise on all gears.

Unknown Quantities (involving noise).

(a) All possibilities of case seventeen?
(b) Bevel gears not adjusted?
(c) Bevel gears not properly shaped?
(d) Bevel gears not lubricated?
(e) Compensating gears deranged?
(f) Lost motion in live axle?
(g) Universal joints worn?
(h) Wheel bearings loose?
(i) Sprockets worn?
(j) Slack sprocket chains?
(k) Lost motion in radius rods?
(l) Lost motion in distance rods?
(m) Propeller shaft twisted?
(n) Jackshaft twisted?
(o) Loose spring shackles?
(p) Steering linkages loose?
(q) Steering knuckle, lost motion?
(r) Lost motion in steering gear?
(s) Flapping mudguard?
(t) Loose hood?
(u) Loose apron?
(v) Squeaks for oil in small bearings?
(w) Body loose on chassis frame?
(x) Click of roller bearing washers?
(y) Spring clamps loose?
(z) Shock absorbers loose?

*Note.—In some cars the direct is on the third speed, in others on the fourth, and there are some designed to give direct drive on both third and fourth. It will be understood that "direct drive" as implied in such cases is a play on language. It is direct as regards the change-gears only. The drive through the bevel gears is not eliminated.

CASE NO. 18—THE CAR RUNS NORMALLY.

Known Quantities (involving maintenance).

(*a*) The motor is sweet running.
(*b*) The transmission is adequate and silent.
(*c*) The compensation (differential) serves the purpose.
(*d*) The live rear axle is silent and satisfactory.
(*e*) The sprockets are silent and satisfactory.
(*f*) The propeller shaft performs properly.
(*g*) The wheels are of adequate diameter and strength.
(*h*) The steering is irreversible and steady.
(*i*) The gear ratio is appropriate to the motor.
(*j*) The cooling system is efficient.
(*k*) The brakes are powerful and dependable.
(*l*) The lubrication is profuse and dependable.
(*m*) The ignition is adequate and free from petty annoyances.
(*n*) Protection from dust and the elements, complete.
(*o*) The tire equipment is good and satisfactory.
(*p*) The carbureter works under all conditions.
(*q*) The fuel supply is adequate.
(*r*) The spring suspension is flexible and satisfactory.
(*s*) The lighting equipment is efficient and dependable.
(*t*) The clutch is not "fierce."
(*u*) The clutch will hold.
(*v*) The bearings are of adequate dimensions for the work.
(*w*) The chassis frame is rigid and strong.
(*x*) The universal joints are strong and free from lost motion.
(*y*) The battery equipment is of ample capacity.
(*z*) The tool kit is complete and appropriate.

Unknown Quantities (involving maintenance).

(*a*) The oil will become acid and etch the polished surfaces?
(*b*) The "decarbonizer" will attack the cylinder surfaces?
(*c*) The "dope" in the fuel will etch the cylinder surfaces?
(*d*) The "inflating gas" will deteriorate the tires?
(*e*) Open wounds in the tires will let dampness into the fabric and enable mildew to attack the same?
(*f*) The leather facings will be burnt if the clutch is permitted to slip?
(*g*) The fiber facings on the brakes will burn out if the brakes are kept "on" while the car is in motion?
(*h*) The sprocket chains will wear out if they are not kept clean and lubricated?
(*i*) The transmission will be noisy if "grease" is not used?
(*j*) The grease in the transmission will do damage if it is not changed regularly?
(*k*) The lubricating oil loses its lubricating properties?
(*l*) The "clash gears" will be bunged up if the shifting is carelessly performed?
(*m*) The springs will deteriorate if they are not kept oiled?
(*n*) The crankshaft will deteriorate the more quickly if the motor is "raced"?
(*o*) Excess lubrication will end in carbon deposits?
(*p*) Excess gasoline defeats power and increases cost?
(*q*) A steady gait ends in the greatest average speed?
(*r*) The car deterioration increases enormously with speeding for short distances, only to violently apply the brakes thus alternating between fast and slow?
(*s*) Parts subjected to "shock" will deteriorate in that the metal is rendered crystalline; the more quickly if the car is abused?
(*t*) Mud left on the body over night takes varnish off with it the next morning?
(*u*) Negotiating curves at high speed does much damage?
(*v*) A maker's guarantee is of no value to a reckless owner?
(*w*) "When the cat is away the mouse will play." The chauffeur does not own the car?
(*x*) Wet rubber cuts easily. Be careful on sloppy roads?
(*y*) Noise in a car is like pain in a man. It indicates some derangement to be looked after before it is too late?
(*z*) In relation to (*a*), (*b*), (*c*) and (*d*), it is to say, if the several products referred to are not appropriate, the owner of a car must assure himself of the characteristics of such products before he takes a chance, for, when the damage is done, he will have to pay the score?

In conclusion, it may be well to say, the "known quantities" as herein referred to are distinguished from the "unknown quantities" in that the first named are certain of identification, while the second are possible and to be looked for; in many cases, the sequences. The unknown quantities (so-called) are put as questions, under the circumstances, and are to be worked through and corrected until the trouble is cured.

EFFECT OF THE SPARE WHEEL ON THE HUB BEARINGS

By HENRY HESS.

THERE is a condition accompanying the use of the spare wheel of that type which is attached to the rim of the regular wheel, such as the Stepney, Burrowes, etc., which is not as yet generally recognized, but is of decided importance, namely, that the use of these wheels will in many cases affect the safety of the wheel bearings very considerably, even to the extent of positively endangering them.

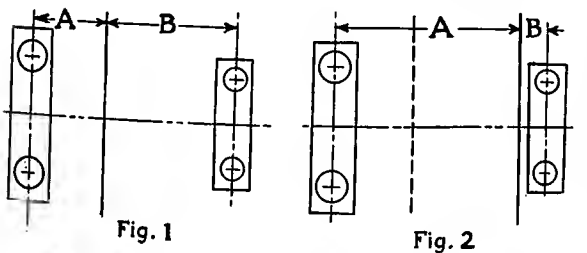

Fig. 1 Fig. 2

Diagram Showing Load Line with and without Spare Wheel.

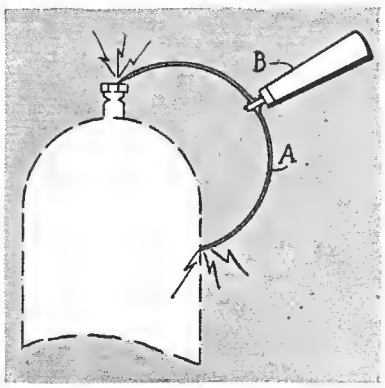
Fig. 1 is a rough diagram indicating the center line of the tread of the regular wheel with reference to the usual arrangement of the ball bearings in the hub. As the plane of the tread passes between them the load sustained by the wheel is divided between the two bearings in inverse proportion to the distances A and B. The bearings are selected for corresponding carrying capacities.

The use of a spare wheel changes the conditions to those indicated in Fig. 2. Here the dotted line is the plane of the regular wheel, as in Fig. 1, but as this wheel no longer carries any load it does not come into consideration. The full vertical line represents the plane of the spare wheel tread; depending upon the size of the tires and the relative location of the bearings, this line may fall within the small outer bearing, in line with it, or even beyond it. In every case the distance B is greatly shortened, with a corresponding increase of load on the outer bearing. This makes the load much larger than originally contemplated, and in all likelihood sufficiently so as to seriously endanger the bearing.

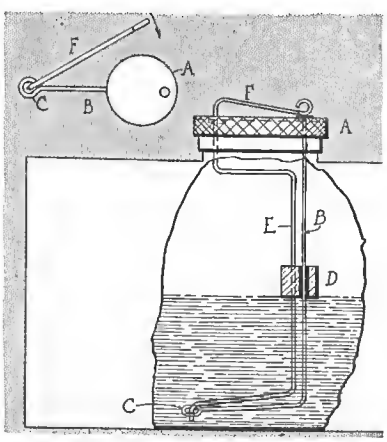
If a spare wheel of this type is to be used, then such use should be restricted to the unavoidable minimum for getting home, and even then cautious driving to avoid all sudden strains is imperative. Undoubtedly these wheels fill a real need, but the user should remember that a broken bearing is not nearly so easy to repair as a puncture.

WRINKLES OF INTEREST TO THE AUTOIST

WHERE a high-tension magneto is employed for ignition, it is rather difficult to test the spark plugs in order to find which one is misfiring, particularly when tbe autoist is not sufficiently familiar with the mechanism of the magneto and its internal connections to figure it out on the latter. Of course, on a coil and battery system it is easy enough to hold down one of the vibrators at a time, taking each cylinder in turn and thus locating the trouble. Or where a dual system of ignition using a set of accumulators and a high-tension magneto operates through the same set of plugs, it is not at all difficult to locate plug troubles, as the battery side may be resorted to, using the coil vibrators in the usual manner. But it is frequently the case that either a single, non-vibrating coil is employed, or there are two entirely independent sets of spark plugs. For testing the plugs under such conditions the simple device shown in the illustration will be found very convenient. To make this, take a piece of stiff wire, *A*, several inches in length and bend in a half circle as indicated. At its center fasten a handle, which for convenience sake must be of insulating material, otherwise it will be not a pleasant device to use. The handle from a discarded knife switcb will serve the purpose admirably, although a wooden one will do equally well where it is kept dry. To test a plug with the aid of this little device, it is only necessary to bring one end of it in contact with the binding post on the plug while the other is allowed to rest against the cylinder, or for that matter any other part of the motor, as it serves to short-circuit the plug to which it is applied, so that if the other three cylinders fire regularly during the operation, the plug under test is the one at fault and should be removed. The testing operation may be carried out very quickly.



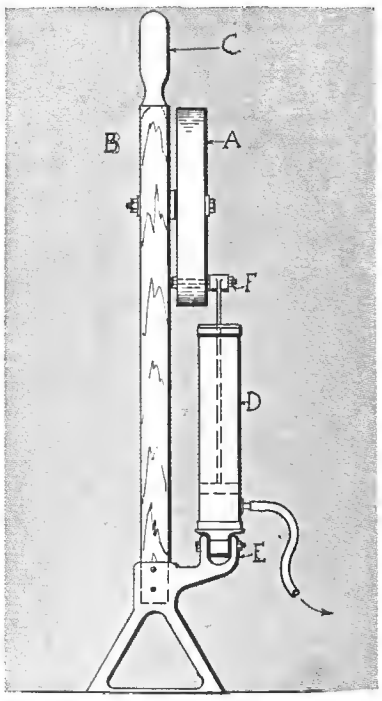
For Testing Spark Plugs.



Details of the Float Mechanism.

A Handy Gauge of Home Make.

To tell how much gasoline there is in the tank is always a matter of guesswork, and a stick is not always handy An easy way to make a gauge tbat is always reliable is as follows: Drill a hole in the tank cap *A* near the edge, and get a strong and stiff piece of wire *B*, long enough to reach to the bottom of the tank *A*. Bend one end at right angles about 1½ inches long and make a small eye *C*, on the end. Get a small cork *D*, and in the center of it put a piece of tubing so it will slide up and down freely. Put the cork on the wire and put it in the tank. Stick the wire through the hole in the cap, and see that the wire is straight up and down and that the end of the wire with the bend in it is on the bottom of the tank. Solder the wire to the cap *A*, where it is. Get another wire *E*, as stiff as the other one and bend it as illustrated. Fasten on the other one. A catch should be soldered on the top of cap *A*, to hold the wire against the cork when it is drawn out. Before the cap is unscrewed to see how much gasoline is in the tank, pull the wire lever *F*, as indicated by arrow in plan view, over on the catch on the cap *A*. This done, the wire will hold the cork *D* at the height the gasoline is, making a very easy way to find out how much gasoline there is in the tank.



Construction of the Power Pump.

Simple Power Pump.

Out of an oak board 1 inch thick cut a disk *A*, 7 inches in diameter, drill a ½-inch hole in the exact center. Put it on a lathe and turn the edge true. Next cut an oak strip *B*, 18 inches long and 1½ inch wide; turn a handle *C*, on one end, and on the other end fix a handle as shown. Now with a ½-inch bolt 2½ inches long fasten disk to oak strip with a washer between. Next get a good strong, and rather short bicycle pump *D*, and fasten to support *E*. Make a head *F*, on the end of the piston rod, with a hole through it, and with a strong wood screw fasten it to the disk *A* about ¼ inch from the edge. Be sure the piston reaches the bottom of the cylinder before the piston rod is cut the right length. The cylinder must be pivoted at the end *E*, so it can move back and forth when the disk *A*, revolves when it is held against a rear wheel. Fasten a rubber tube to the pump long enough to reach all the wheels, with a valve connection on the end; jack up one of the back wheels, throw in the low gear and hold the disk against the tire, and the pump will do the rest.

Avoid Using Abrasive Tools.

One of the commonest failings of the amateur autoist is to resort to the pipe wrench or the gas pipe pliers to loosen a refractory nut or connection, but any man who takes pride in the appearance of his motor and its fittings will avoid this religiously as one of the most important of the many "Don'ts." Such tools were never intended to turn nuts or similar fittings, and, as they only grip by sinking into the metal, the slightest slip means an abrasion of the metal that cannot be remedied. Square and hexagonal nuts soon become round and then shapeless, while tubing is hopelessly marred.

LETTERS INTERESTING AND INSTRUCTIVE

INFORMATION WANTED ABOUT IOWA LAWS.

Editor THE AUTOMOBILE:

[1,541.]—I would like to know where one can obtain a book containing the automobile laws of Iowa or laws on the right of way. I want to know this especially: an automobilist comes up behind a team and blows bis horn; the team keeps the road, and, ae tne automobile turns out to pass, the driver wavee his band as a signal to stop; if tbe automobiliet keeps on, ie he responsible for dsmages in case the horses are ecared?

I also want to know how to figure horeepower by the A. L. A. M. formula.

R. F. JOHNSTON.

Farragut, Ia.

Information about the Iowa automobile laws can be obtained from the Secretary of State, Des Moines. We do not know whether it is published in book form, however. Section 9 of the law of 1904 reads: "Any person operating a motor vehicle shall, at request or on signal by putting up the hand, from a person riding or driving a restless horse or other draft or domestic animals, bring such motor vehicle immediately to a stop, and, if traveling in the opposite direction, remain stationary, so long as may be reasonable to allow such horse or animals to pass, and if traveling in the same direction, use reasonable caution in passing such horse or animals, and the operator and occupants of any motor vehicle shall render necessary assistance to the party having in charge said horse or other draft animal so passing." Nothing is said about responsibility for accidents.

The A. L. A. M. formula is bore of cylinders in inches, squared, times number of cylinders, divided by two and one-half, equals horsepower.

BATTERY WIRING AND LUBRICATION.

Editor THE AUTOMOBILE:

[1,542.]—1. When using eight dry cells, should they be connected in series parallel, or in sets of four each connected series multiple?

2. My double-opposed motor runs much quieter when the crankcase is filled with oil to the extent that the exhaust smokes. By attaching baffle plates to the cylinders could thie same oil level be maintained without the oil reaching the combustion chamber to such an extent, and if eo, how ehould the baffle plates be made and attached?

SUBSCRIBER.

Columbia, Tenn.

The best arrangement is the series-multiple, as shown in the diagram on page 297 of THE AUTOMOBILE of August 27. This wiring gives the voltage of four cells, that is, from four to six volts, and the amperage of two. Series-parallel and series-multiple are one and the same thing. Putting all eight cells in series would be apt to injure the coils and their vibrators.

The baffle plates would not do much good on a horizontal engine, as when the oil reached any considerable height in the crankcase it would begin to flow through the slot for the connecting rod. In a vertical motor only the splash has to be considered, and here the baffle plates are very effective. The best plan would be to find the cause of the noise and correct it, instead of trying to muffle it with the oil. Very likely the connecting rod big ends need adjustment.

WHEN DO THE FACTORIES WORK HARDEST?

Editor THE AUTOMOBILE:

[1,543.]—During a discuesion, the question arose as to whether the automobile factories are rushed harder during the Summer months than in the Fall and Winter. Will you kindly eettle the dispute by giving your opinion on the same?

M. HORENSTEIN.

Uncasville, Conn.

The rush season depends largely on the factory, but it is much more likely to come in the Winter than in the Summer, because most buyers want their cars delivered in the Spring. All the larger factories, however, work on a regular schedule and have neither rushes nor lay-offs.

A CURE WITHOUT AN EXPLANATION.

Editor THE AUTOMOBILE:

[1,544.]—I have read with great interest Letter No. 1529, under "Letters Interesting and Instructive" in your issue of September 3, as I experienced exactly the same trouble, which was finally corrected after two months of experimenting. The float feed carbureter with metal float on my four-cylinder car persistently dripped gasoline after the engine was stopped, although I was absolutely certain that the valve wae tight. I purchased a new float and this did not correct the difficulty, and after lowering the level by small increments finally gave up and returned the complete carbureter to the factory for repair. When received and installed the trouble was worse than ever. Against the advice of other motoriets I began experimenting by adding weight to the float by means of wire wound about body, and after a few trials found that this completely overcame the dripping. I then removed the wire and after carefully weighing it on delicate scales, flowed an equal amount of solder on the bottom of float and have since had no trouble whatever. This method has recently been applied to another curbureter suffering with same symptoms and again effected a permanent cure.

E. M. KINNEY.

Schenectady, N. Y.

We have no doubt as to the permanency or effectiveness of the cure, which you state was accomplished in two separate cases on different carbureters, but must acknowledge ourselves at a loss as to the principle on which the remedy was applied. In other words, we find it difficult to understand why, when a certain level of gasoline in the float chamber causes the carbureter to drip after the engine is stopped, raising that level should prevent the dripping. Exactly what causes the dripping in the first place does not seem to have been settled, or in fact, any explanation attempted. It may be that the hot manifold continues to vaporize gasoline after the motor stops, and having no outlet this condenses and then drips out as the metal gets cold, but such an explanation is not plausible in view of the cure effected by means of raising the level, as this would only tend to aggravate matters. We would like to hear more about the case, as well as from other readers who have had similar experiences.

MR. DURYEA ON VARIED SUBJECTS.

Editor THE AUTOMOBILE:

[1,545.]—I fear your zeal in defenee of the four-cylinder form has led you into more grievous error than my defense of the three showed. Your etatement that the difference between one-ninth and one-sixteenth is 40 per cent. reminds me of the Pennsylvania Dutchman who leased his farm for oil purposes and was to receive one-eighth of the oil as rental. This looked like so small a part of the wealth boiling out of his ground that hie cupidity would not let him rest, so he asked for a new contract, and after some talking an ironclad one granting him a rental of one-twelfth was executed. It took a lot of explanation to make clear to him that he now got isse than before, and he exclaimed: "Well! I never knew before that eight wae more than twelve."

The difference is less than five per cent., which amount is eo small that many people cannot notice it. An expert in such matters can by actual test notice two per cent. difference in vibration, but this is only possible at slow speeds when the impulses are far apart. At the speeds now commonly used, with other things identical except that the three-cylinder for a given power must be a little larger than the four and have a slightly larger flywheel, very few people can tell by riding in the vehicle which motor is pulling them.

High compressions are not so common as they were a few years ago, and the fact that the public uses anything does not prove it best. As a matter of fact the masses are nearly always behind. Most of them are still using horses.

Say to "Inventor" that the belt drive is a delusion. The way those belts will run off the pulleys on bad roads will surprise him. They are fine in a shop where things etay in line, but on the roads found in America the belts are in the wrong place when hard work is to be done. Duryeas were belt-driven for a while because the public asked us why we did not use this "simple system" inetead of the splendid spur gear and individual system adopted by us in '93. The public is elowly learning what it ought to have, and when it does learn ae much on this subject ae the makers know then it will be proper to give it what it wants; but in the years gone by

every attempt to give what was wanted even though wrong had been bad for somebody or other in practically every instance.

If Mr. Waldin will grind the float valve he will stop the dripping from his carbureter. The float has very little lifting ability and so does not force the valve onto its seat very effectively. This necessitates most careful grinding. If a little trace of soap is on the seat it will hold better. I favor a valve point as small as possible, so that the float can work to the best advantage.

Without wishing to appear as criticizing Mr. Fay's able and instructive article, I call attention to the fact that the "Times-Herald" contest at Chicago in 1895 was won by a Duryea having a spray carbureter and Duryea rigs that used this device for several years before this. The fuel tank in most of the early Duryeas was placed where any leak could not drop on the motor, and this meant under the floor, so a pump was used to raise the fuel to the carbureter, which was near the engine, where it was warm. The float was adopted in 1897, and the auxiliary air valve in '98.

I feel sure Mr. Fay's remarks do not apply to the type of carbureter used on the Duryea rigs all these years. They have usually been open so the spray could be seen by looking into the open end and the fan shape of the particles of liquid as they left the small nozzle showed very plainly that there was no stream. The passing air travels so much faster than the liquid at that point that it tears off each projecting particle of liquid and carries it away as a small spray globule. This was easily proved by detaching the suction pipe and blowing through the carbureter.

If the carbureter was capable of doing its duty, each puff of one's breath would produce a fog so fine that it could not be seen unless in good light, although one's hand would wet quickly if held in line. If there were large drops present the carbureter had some fault which could usually be seen. I am not able to understand why there should be any difference in the performance of the carbureter when sucked through and blown through. The air moves as a result of a difference in pressure on opposite ends of the air passage, and if there is no connection with the gasoline surface the fact that these pressures are slightly nearer to atmospheric in one case than in the other can certainly not produce a spray in one case and a stream in the other, as is asserted.

CHAS. E. DURYEA.

Reading, Pa.

Mr. Duryea's arithmetic is startling, to say the least, and it would be very interesting to know how he arrived at the conclusion that the difference between one-ninth and one-sixteenth is only five per cent. However, until he brings forward some additional proof we shall stick to our original assertion that the difference is 40, or, to be exact, 43.75 per cent. For the rest, we have a great deal of faith in public opinion. It has been found right many more times than wrong, and usually has pretty good foundation for its decisions.

AUTO NEWS FROM THE SUNNY SOUTH.

Editor THE AUTOMOBILE:

[1,546.]—I am a subscriber to both your magazines, "The Automobile" and "Motor Age," and read them with interest, but very seldom see anything in them from this section of the South, and would like to state that we are not altogether dead to the automobile world.

We have a little city of 50,000 inhabitants, and among them a number of automobile enthusiasts. There are about 200 cars registered in the city; among them are the Oldsmobile, White, Franklin, Maxwell, Buick, Mitchell, Thomas, Chalmers-Detroit, Ford, Bianchi, Elmore, Matheson, Packard, Peerless, Stevens, Pope-Toledo, Rambler, Studebaker, Holsman, Schacht, Babcock, Pope-Waverly, and others.

There are two up-to-date garages in the city and several repair shops, and all of them have experienced mechanics and turn out good work. The roads in the county are in very fair shape and with a little work could be put in good condition. Mr. Lamar of this city, who drives an Oldsmobile roadster, has just completed a run from Macon, Ga., to Lansing, Mich., and return, a distance of over 3,200 miles, without any mishap, and reports a great trip. The outlook for the fall and winter auto trade here is good, and I think the agents here will do fine business.

Macon, Ga. S. R. JAQUES, JR.

If it is seldom that the South is heard from, it is evidently not because there is a dearth of automobiles there, to judge from your letter, but simply because the doings of their owners are not allowed to find their way over the "line." On this account, people are apt to come to the conclusion that there is little automobile news from the "land of cotton" because there are no automobiles down there to hear about. The chief thing lacking appears to be a live press agent. We would be only too glad to publish more news about the auto enthusiasts in the South.

IDEAL CARS ARE STILL POPULAR.

Editor THE AUTOMOBILE:

[1,547.]—Unless you have rung the bell on "ideal cars," I should like to submit one. Let it be understood that this is primarily a touring car. It is doubtful if any man could get up a car ideal for all purposes. Specifications:

Body—Straight line, five passengers, touring, metal.

Wheelbase—124 inches.

Tires—Front and rear, 36 by 4 1-2; demountable rims.

Axles—I beam front and rear.

Drive—Double side chains with mud-proof, dust-proof, and oil-tight metal chain case, something similar to that on the Chadwick Great Six.

Springs—Front, semi-elliptic, with side rail attachment for rear ends as on 1908 50-horsepower American Tourist; rear, platform.

Steering—Thread and nut, 17-inch wheel.

Cooling—Water, flat tube radiator, modified square in shape (American Tourist) to allow of greatest capacity within given limits.

Brakes—Three sets; regular hand and foot brakes, both being internal expanding, side by side in wide drums on rear wheels, as on the American Roadster, and an extra foot brake on the jackshaft, not to be used regularly, in order to save the chains.

Motor—Four-cycle with four offset cylinders cast in pairs. Valves large, though all on same side. Bore, 5 1-4; stroke, 5 1-2 (American Roadster).

Ignition—Double jump spark with high tension magneto and battery systems.

Lubrication—Splash, force feed. Pipes to cylinder walls and two to crankcase, divided into two separate compartments, as on Peerless.

Clutch—Disc, Stevens-Duryea type.

Flexible Joints—Two between clutch and transmission, similar to arrangement on Peerless.

Transmission—Four-speed selective, with direct drive on both third and fourth speeds as on 1908 40-45 Isotta Fraschini.

Bearings—All ball, except engine, which should be plain.

The ideal touring car should be chain driven, because when chains are encased as specified, none of the objections usually urged against this type apply, and because this construction is lighter and gives a better weight distribution, meaning less wear on tires, especially rear ones, and a car that rides better and behaves better generally on anything but perfect roads.

Furthermore, this construction admits of the type of transmission specified, highly desirable for a touring car, to be used in mountainous as well as level country, and permits of the unit construction of the transmission and driving gears, the advantages of which have been so extolled lately without resorting to the expedient, monstrous on a high-powered touring car, of mounting the transmission on the rear axle, as on some shaft-driven cars to-day.

Touring by Americans of America, where we cannot hope to have consistently good roads for many, many years, is just beginning to be popular. American manufacturers are, therefore, making a mistake in accepting as final the present popularity of the shaft-driven type, acquired by the use of cars for by far the most part, for pleasure driving in and around cities and suburbs. Instead they should exercise a little ingenuity to develop a satisfactory chain case, thereby perfecting the superior type of vehicle for touring, if, in fact, not all purposes, and one for which there will be a great demand when its advantages are more universally understood and after automobilists generally have had more experience with our country roads. DEMAREST LLOYD.

Redstone, N. H.

Your specifications are certainly specific enough. We think, however, that you will find several cars on the market which conform pretty closely to your principal requirements.

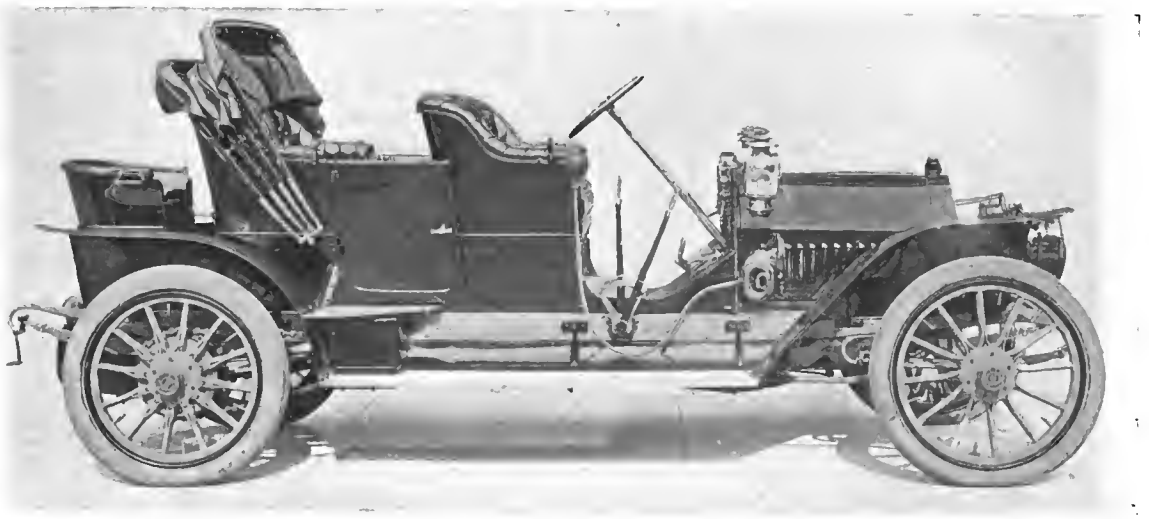
A YOUTHFUL AUTOIST FROM KENTUCKY.

Editor THE AUTOMOBILE:

[1,548.]—I am a little girl eleven years old. I have just been reading in papa's journal about Miss Bernice Haynes driving a car, and I was very much interested. I have been driving papa's car a little ever since I was eight years old, and, like Miss Haynes, I began by driving around the block alone on the low gear, and now mamma and I go most anywhere by ourselves over our beautiful Kentucky roads. "Dad" insists on the engine being stopped whenever we leave the car, so I think I can give Miss Haynes a pointer on getting it started. I find a place to stop with the car's head a little down hill, and, when we get ready to start, turn on the switch with the spark lever well back, throw off the brake, and, when we get going some, throw in the high gear, and away we go without cranking.

Papa says he would rather trust us out with "Old Cadillac" than with a horse, and I have never been towed in. Papa is teaching me how to care for the engine and make adjustments, and I am getting so I understand it pretty well.

Versailles, Ky. NATALIE H. BROTHER.



1909 Model of American Locomotive Car, fitted with Close-coupled Body.

THE AMERICAN LOCOMOTIVE CAR FOR NEXT YEAR

THOSE who have been interested in the product of the American Locomotive Company and the progress of American manufacturers will be glad to learn of the new policy and prices for 1909. Manager James Joyce made the statement that hereafter no Berliet cars would be made in this country, although the American Locomotive car from the same factory at Providence will be practically the same car in design and material. The name will be different, but otherwise it will be unchanged except by improvements in details. The Locomotive Company made the three-year contract with the French manufacturers in order that they might purchase experience, and it was not to be expected that the contract would be renewed. They feel that during this time they have accomplished their object with a perfect organization and can now do better working independently.

The terms of the contract—it is important to note—permit the American Locomotive Company to perpetuate in its future models any of the features of the French design used during the life of the contract. On the other hand, the contract required so close a duplication of the French model that certain desirable changes, making it more suited to this country, were prohibited. It will now be possible to make all these adaptations and at the same time retain the design and maintain the high quality.

Relieved from the payment of royalty and free to market its product under its own name and on its own terms, they have been able to make a large reduction in prices, so that now the American Locomotive car will be about the same as the ordinary high-grade American car. The six-cylinder car at $6,000, the 40-horsepower car at $5,000, the town car at $4,500, and a cab at $3,350 prescnt a fine line of automobiles with the prestige of an old-established company with $50,000,000 capital.

CARBONIC ACID AS A TIRE INFLATOR.

PARIS, Sept. 10.—Carbonic acid is worthless for inflating pneumatic tires, declares a Michelin expert. In view of a certain revival in the use of this gas for purposes of inflation, careful experiments have been made at the Cleremont-Ferrand factory in order to accurately test the length of inflation of tires pumped up with atmospheric air and with carbonic acid gas. Six different air chambers of one, two and three millimeters thickness were inflated, one of each having atmospheric air pumped into it to a pressure of 6.6 pounds, and three others taking carbonic acid to the same extent. They were left under observation for 72 hours, when it was discovered that their degree of inflation was as follows:

Thickness of tube.	Inflated with atmospheric air.	Inflated with carbonic acid gas.
1 millimeter	5.9 pounds.	1.3 pounds.
2 millimeters	6.3 pounds.	1.8 pounds.
3 millimeters	6.4 pounds.	2.3 pounds.

The experiment was made in an atmosphere of 64 to 68 degrees Fahr. A similar experiment with the same initial pressure but with the exterior air at 95 to 102 degrees Fahr. was even more in favor of natural air as a tire inflater, the results being:

Thickness of tube.	Inflated with atmospheric air.	Inflated with carbonic acid gas.
1 millimeter	3.5 pounds.	0 pounds.
2 millimeter	4.8 pounds.	.2 pounds (about)
3 millimeter	5.4 pounds.	.3 to .4 pounds.

EXPORTS SHOW SLIGHT FALLING OFF.

According to the Government reports for July, the number of automobiles shipped abroad by American manufacturers for the seven months of 1908 ending with July is considerably below the number for the corresponding period of 1907. It is worthy of note that, even with this falling off in the number shipped to foreign users, the grade of machines seems to have been of a much higher class, for during the first seven months of 1907 the custom records show that 2,052 machines having a total valuation of $3,825,969, while for a like period this year only 1,528 machines were sent abroad, but their total valuation of $3,225,166 is nearly equal to that of 1907. From these figures we are led to infer that the higher classed American product is meeting with increased favor across the water. As regards the automobile trade of foreign makers in this country there seems to be little change in the amount of business they are doing here, so far as the number of machines is concerned, although the figures show a very substantial falling off in their total value, during the first seven months of 1907 the foreign manufacturers imported 559 machines, valued at $1,827,590, and for the same period this year 558 machines, valued at $1,170,624. France, as usual, leads the list of foreign countries shipping to this side, with over 400 cars for these seven months, both last year and this.

AUTOMOBILE WAGONS TO CARRY AUTOS.

PARIS, Sept. 10.—Automobiles requiring to be shipped from one end of France to the other need no longer be mounted on an open truck and covered with a tarpaulin if the Paris-Lyons-Meditérranée Railroad is used. This company has just had constructed eighty special covered wagons specially designed for the transportation of automobiles. Entrance is at each end by full hinged doors opening outwards, sliding side doors being also provided for the entrance of persons only. The interior of each wagon is so fitted that the largest or the smallest automobile can be secured in a few minutes, without any possibility of it working loose under the greatest sbocks and without any danger of the paintwork being scratched. Movable bars with suitably shaped blocks attached to them fit in grooves ready to be brought to the front and rear of each axle and there secured by stout pins. Heavy leather straps give further security, and rolling is prevented by other attachments to the body of the car.

With the use of these wagons all that will be necessary for the transport of a large car will be to run it to the depot under its power, enter it in the wagon, draw off the gasoline as a precautionary measure, and attach it. No packing whatever is required, and on arrival at destination the automobile needs no more attention than if it were being brought out of the garage. The new railroad wagons will be principally used for the transportation of powerful open and closed cars from Paris to the southern pleasure and health resorts, the travel to which is very heavy the greater portion of the year.

AN EXAMPLE OF HIGH-GRADE BODY WORK.

One of the handsomest, not to say the largest, automobiles in New York City left the shops of Locke & Company, body builders, last week. The chassis is a 50-60-horsepower six-cylinder Renault; its wheelbase is approximately 13 feet, allowing ample accommodation for a roomy seven-passenger body. The two extra seats in the tonneau are fixed and of the bucket type, nearly as wide as those in front; a passage between them gives entrance to the rear seat. The body is finished in a rich, dark blue with cream striping, pleasingly relieved by the "basket work" on the upper panels of the seats. Equipment includes a five-bow folding top and a Huillier flexibly mounted glass wind shield, a type not often seen in this country.

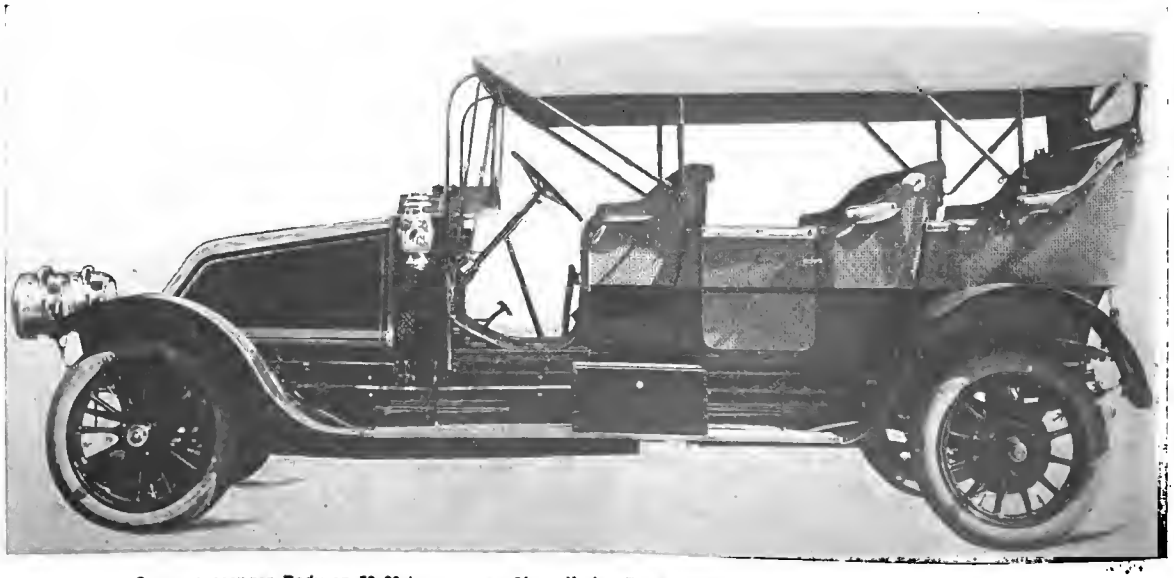
A CALIFORNIA CRUISE OF STEAMERS.

SAN FRANCISCO, Sept. 12.—Forty-three White steamers manned by 260 persons, and under command of Admiral C. A. Hawkins, formed the northern division of the "White Squadron," as it made its first cruise on a recent Sunday to Muir redwoods. The success of the occasion was greater than was anticipated, notwithstanding an occasional call on the tire-repair wagon for assistance, as the roads were very rough in places. The ferryboat *Ukiah* has been chartered in this city to transport the "steamers" across the bay, where squadron formation was called by Admiral Hawkins. The route taken was over the Bolinas road, and up the creek road, as the former route was not in condition to be traveled. Up the creek to the redwoods, it became a veritable cruise, as the water was up to the hubs of the cars most of the time, on account of the many fords. Anchored in the snug harbor of the Muir redwoods, the hungry officers and their crews partook of the bounteous luncheon which had been prepared for them at Muir Tavern. When luncheon was over, several hours were spent in exploring the redwood canyon, which has lately been acquired by the government.

Most of the steamers were navigated by their owners, many coming from a distance, from Santa Cruz, San Jose, and Oakland to participate. The return cruise was made over the ridge by way of Mill Valley, and the return trip of the *Ukiah* was made with forty-five machines aboard. There was almost every model of White steamer to be seen, from the little back-entrance car to the fine big straight-line body steamers. What speaks most forcibly of the success for the event was the cry to be heard on all sides: "When can we have another cruise?"

The Austrian industrial car contest, under the patronage of the war ministry and chamber of commerce, will take place from October 20 to 31 on a circuit of 800 kilometers for vehicles bearing a load of more than 2,500 kilograms, and 1,000 kilometers for those carrying less. Only internal combustion motors are eligible, and they all have to be fitted with a tank capable of carrying sufficient fuel for the daily stage; neither may their weight, fully laden, exceed 9,000 kilograms.

Many real estate agencies near New York City use automobiles to show prospective customers their lots. But the purchaser is often disenchanted when for the first time he has to walk to the station.



Seven-passenger Body on 50-60-horsepower Six-cylinder Renault—One of the Largest Bodies Ever Built.

ONE-PIECE PRESSED STEEL REAR AXLE.

Among the many new products of the Timken Roller Bearing Company for 1909 is their new one-piece pressed steel tubular power axle, which they hope to put upon the market at an early date. One of the great troubles with the present form of built up axles is that a truss is necessary to take the strains. The Timken Company in manufacturing this new axle have made use

Fig. 1.—Rear view of rear axle, showing absence of protruding parts to catch road dust and mud.

of a special basic open hearth steel of high static resistance so designed that the axle itself will carry the load without the requirements of a truss. Advantage has been taken of the fact that tubular forms give great strength and resistance is distributed proportionally to the points of greatest stress by grading the thickness of the metal so that the heaviest part comes at the spring seats where the strains are greatest and the thinner parts toward the center.

Fig. 2.—Front view of rear axle showing gear carrier, spring bases, and brakes, comprising the complete unit.

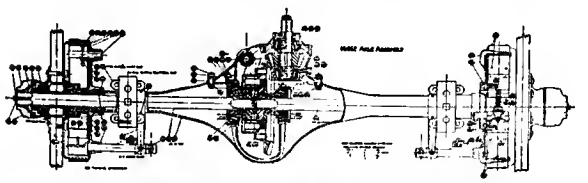


Fig. 3.—Plan view of one-piece rear axle, gear carrier, brakes, and wheels, illustrating method of placing gears.

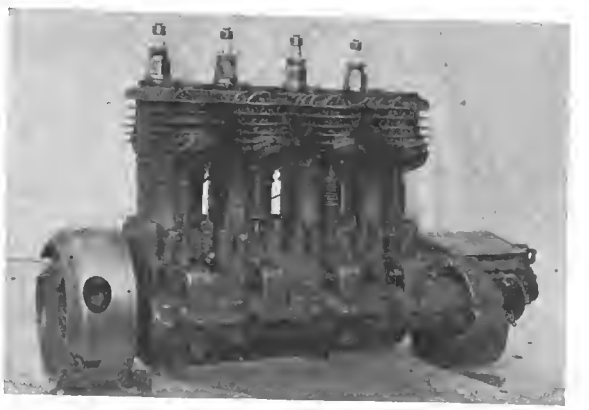
As the accompanying cuts will show the designer has done away with all sharp curves thus avoiding any sudden angles which sometimes add leverage and increase the liability of shocks at the points of least resistance. Such a design not only gives stability but it makes a very clean cut and smooth looking axle, with no extra parts to get loose and easy to clean.

Fig. 4.—One-piece pressed steel rear axle housing.

This axle is designed to be used on cars weighing up to 3,000 pounds empty and of 45 H. P. or less.

Supplementary to this new axle, the Timken Company have about completed a new differential gear carrier, torque bar arrangement and improved brake equipment that will shortly make its appearance on the American market.



Inlet Side of Planche Motor, Showing Magneto.

A LIGHT FOUR-CYLINDER BICYCLE MOTOR.

The Motor Car Specialty Company, of Trenton, N. J., has brought out a four-cylinder air-cooled motor, called the "Planche," which they believe is the smallest four-cylinder motor ever manufactured in the United States. It was designed to drive motorcycles, but is suitable for any purpose where a light four-cylinder motor is required. The cylinders are 2 1-16-inch bore by 2 1-4-inch stroke and both cylinders and pistons are finished by grinding. Cooling flanges are cast integral. Both inlet and exhaust valves are mechanically operated, and are on opposite sides of the cylinder; they have nickel-steel heads and carbon-steel stems. The crankshaft is forged of 40-point carbon steel with hardened journals, running in plain cast-iron bearings; the camshafts are also hardened. The motor is fitted with a Simms-Bosch magneto, inverted and driven from the front end of the crankshaft. This model at 2,000 r.p.m develops about 6 horsepower. The weight, without magneto, is 54 pounds.

SOME MISINFORMING INFORMATION.

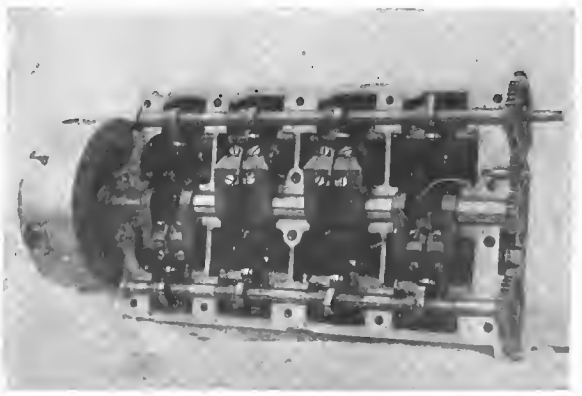
(From Our Press Clippings.)

One of the hardest things to teach a new hand is not to leave the speed gears in the mesh *while the motor is running.*

Don't fill acetylene gas *lamps* with carbide until they are to be used, as carbide is very susceptible to moisture and slacks readily on exposure to air.

An idea of the utility of the *automobile* may be had from the fact that the average carrier can transport, in a *wheelbarrow,* 150 pounds ten miles a day.

On a good road, the average 2,500-pound car, with a *6 x 7-inch* opposed motor, carrying five passengers, should cover seventeen to eighteen miles to the gallon of gasoline.



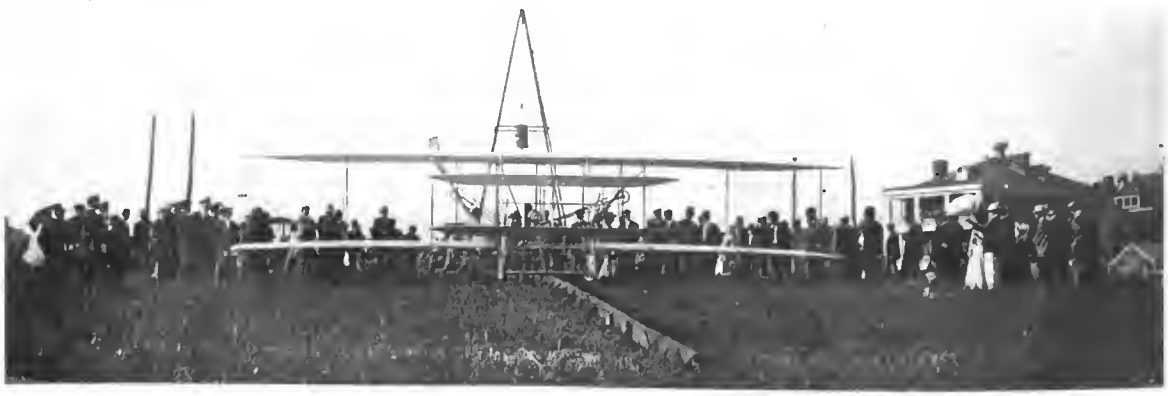
Bottom View Planche Motor—Lower Half of Case Removed.

HOW ORVILLE WRIGHT MADE HIS FLIGHTS

By E. PERCY NOEL

WASHINGTON, D. C., Sept. 14.—It was with an almost audible screech of victory that the great white eagle of the Wright brothers raced directly over the head of Major Fournier, military *attaché* of the French embassy, on September 9. To the hundred or more automobilists whose cars were lined up just off the aeronautic field of the United States government at Fort Myer, Va., it was plain that although the French may claim the earliest practical development of the automobile of the road, the United States stood first in building the true automobile of the sky as embodied in the Wright machine.

A memorable occasion it was—the day that will go down in the world's history, and notably in the long list of achievements of the automobile engine. For, if it was not the day on which the subjugation of the air began, it marks the time when the universe awoke to the fact that man with a motor-driven machine, heavier than the air, can successfully fly through the atmosphere. At this time Orville Wright, the man, and a 30-horsepower four-cylinder twin-screw Wright brothers' aeroplane, the machine, made three runs, each of which exceeded all previous true mechanical flight records, and two of which doubled all such records, official or claimed, in the world.



Wright Aeroplane on the Experimental Grounds at Fort Myer, Va., Showing the Starting Rail.

Little wonder, then, that Cabinet members and other high officials, to say nothing of a thousand spectators, felt the thrill of tremendous excitement and declared that they had witnessed the most marvelous sight of their lives, realizing, many for the first time, that aeral transit is practical!

Mere words cannot convey the feeling that the first sight of this capable sky motor produces in the human mind as it skims the air with and against the wind, up, down and around about. When it touches the ground the mounted soldiers are for a minute dazed, the spectators, respectful yet mad with enthusiasm, rush in one big tumbling mass to surround the aviator and his machine. They fight for the touch of his hand. Women become hysterical and even the seasoned men of war and of the press are, as the slang has it, "rattled."

"He will rest on his laurels now," said someone when the hero of the ninth, did not go to the field next day for an early morning flight. But not Wright. In the afternoon and in others following he mounted his apparatus and soon after his machine slid off the starting track to break the record of the day before. And in this way he will continue, rapidly climbing higher in achievement until he is ready to make the official trials before the board of tests of the United States Signal Corps. What he will do then will be insignificant in his estimation; a run of five miles straightaway and return at the rate of 40 miles an hour, and endurance drive of one hour—in each case carrying with him a passenger.

It was with his two-man run that Wright clinched his claims upon aerial success on the memorial ninth. Perhaps he thought he might as well do it all in one day, but it is more probable that this man who is so unassuming in his manner and speech, thought little of the history he was making. This flight, which began shortly before 7 o'clock might have been continued as long as the one that preceeded but that darkness came on, with only the golden harvest moon and late twilight to illuminate the field.

On the morning of the record-breaking day Wright went aloft at about half-past eight before a handful of people, mostly his friends. He remained in the air 57 minutes 31 seconds, making 57 large ovals in space. Because of the purely friendly character of his audience, he was easy and comfortable in his seat, and the absolute calm that prevailed made him less and less cautious as he swung around his course. Frequently he waved his band to the happy ones below; once he adjusted his cap and even turned to look at the motor a few feet to the right of him. Plainly it was not essential that he tightly clasp the levers—two at his right and one at his left—under favorable conditions. He explained afterward that he could hold the right levers in place with his knee and that the left lever was always held quite securely by a band brake.

Wright had said a few days before that he would not take any chances of breaking his machine until the time came for the official trials, because the aeroplane is the only immediately available one and that it must be delivered on schedule time. But on this morning flight he took great risks. He flew the highest that he had previously taken the machine aloft, rising to a height of 125 feet; afterward he increased it to 250 feet. He made his elongated circles so extended that he passed over rough underbrush, and even the top of the aeroplane hangar.

When it was over and the field telephone was transmitting the news to the city to be flashed over the face of the earth, Wright's mechanic asked him: "Why didn't you stay up an hour?"

"An hour?" asked the aviator. "How long was I up?" And when told, he said: "I thought it was about 40 minutes. Could have stayed an hour as well as not. My eyes hurt me a little, so I thought I would stop."

When he announced that he would make another run in the afternoon at 5 o'clock, the chief servants of the Republic were

notified, and many of them, including the Secretary of War, the Secretary of the Navy and the Secretary of Commerce and Labor, drove out in government automobiles to see the aeroplane. Everyone of them admitted the thrill of the occasion when the machine started off in a businesslike manner and again and again flew directly over them.

THE AUTOMOBILE correspondent stood beside the battle-scarred Secretary of War. "Do you feel a little thrill?" he questioned.

The stolid face reflected a smile as the veteran of war admitted, "Yes, I do. It's wonderful, marvelous!"

The Secretary of War had never seen an aeroplane aloft before. He has never been very enthusiastic about the aerial future.

"Can you see the practicability of it?"

"That's another question——" and just then the white bird with its fusillade of open exhausts that make conversation impossible, flew just 20 feet above our heads. Afterward he stated that he could not see much utility for the apparatus in its present form, but that he could foresee that there was a practical future in development of the basic ideas represented.

Meantime the ungainly thing, that had become that day something beautiful, ran evenly at an altitude of about 75 feet, the steadily-firing motor never missing an explosion until 50 long laps of nearly a mile in average length had been accomplished. The hands of the stop-watches were nearing the hour.

"Give him a cheer when he comes round, and make it good and loud," shouted an officer.

Then the hour elapsed, and the sky motor approached the starting track, and the spectators assembled behind it. As he made his turn a cheer rose so loud that the aviator heard it above the exhaust explosions of his motor, and, releasing the right levers for the first time, he waved his hand repeatedly. The crowd cheered louder than ever and a hundred motor horns joined the enthusiastic chorus. Every lap that Wright added after that the cheering was repeated. When he alighted a few minutes later, almost at the feet of the high officials, his time was 1 hour 2 minutes 15 seconds.

Official time was taken by Augustus Post, secretary of the Aero Club of America, who had never missed an hour at the field while Wright has been there.

"Do you want to go?" asked Wright of Lieut. Frank P. Lahm, soon after the descent.

"I should be delighted," replied the officer.

Somehow they wormed their way out of the crowd that was 15 deep around them, and walked half-way down the field. There the lieutenant received his instructions. While these two talked, the machine was again mounted on the starting rail, the weights hauled up in the derrick and all made ready.

Lieut. Lahm climbed into the right-hand seat, nearest the motor, and as he did so his cap struck the cord that is used to shut off the gasoline for stopping the engine. The unexpected stoppage caused some anxiety among the spectators, but it was over in a minute, as the mechanics cranked over again by pulling on the propeller blades. The motor rattled steadily for a few seconds. Then Wright touched the weight trigger and the machine with its two passengers on the seat that measures 28 inches in length by 8 inches wide, slid down the track and shot off at the end, a foot from the ground.

The aeroplane did not immediately rise from this elevation, but continued for several hundred feet, roughly brushing the grasses. Then Wright tilted his forward balancer and all rose to a height of about 15 feet. At this altitude a long turn was made. On the next circuit the machine rose higher from the earth, and finally attained a maximum height of about 40 feet. Approaching night stopped the run after the two men had been 6 minutes 26 seconds aloft, having covered fully 4 1-2 miles.

Wright does not control the motor while in the air, and he did not advance the make-and-break spark from its usual point when alone before taking up a passenger with him. In spite of this the speed of the machine was approximately 36 miles an hour. He believes that by opening up the motor's speed fully he will be able to fly at least at 45 miles an hour.

On the day following, September 10, Wright added three minutes to his time record of the day before. What was more interesting, he rose to a height of fully 200 feet, and at that elevation completed many long ovals. It was the first long demonstration in a stiff breeze and was for that reason important. The anemometer showed a wind speed of not less than nine and as much as ten for the 1 hour 5 minutes and 52 seconds that the machine was in the air.

Orville Wright Preparing for Record-breaking Flight.

After the flight two cables were handed to the aviator. One from his brother Wilbur and the other, it is thought, from England. Wright would not allow the latter to be published, but intimated that it was from an amusement manager. The quiet little unassuming hero does not care for that kind of publicity. The cable from Wilbur Wright was in code, except for the last two words—*"Très bien."*

After the success of the ninth, THE AUTOMOBILE correspondent propounded a hypothetical question: "Now, Mr. Wright, that you have established such remarkable records in America, is it not probable that your brother Wilbur in France will immediately begin to make longer flights?" The avaitor smiled and would not answer; but it was not hard to guess why the first great achievement of these men took place in the United States.

On September 10 Wright remained in the air one hour, five minutes 52 seconds; September 11 his time was one hour 10 minutes 24 seconds. On the day following, before a crowd of 5,000 people, many well known, he broke two of his own records. Carrying with him Major Geo. D. Squier, acting chief of the United States Signal Corps, he remained aloft nine minutes six and one-third seconds, traveling at the rate of 38¾ miles an hour. Flying alone, he was in the air one hour 14 minutes 25 seconds, making 71 great ovals in the air.

In the Air Making a New World's Record.

Mr. and Mrs. Macfarland and Their Reo In Which They Toured.

LONG before we were the owners of an automobile, it had been one of out great desires to make a thorough trip of New England. When we became autoists, our old ambition was revived. The opportune time came this summer for a comprehensive survey of the impressivc grandeur of the White Mountains, and the most pastoral scenery of the Green Mountains. When Saturday, the first day of our vacation, dawned we were ready to start at 6 A. M. for Stockbridge, Mass., a distance of 145 miles. Our route lay via Portchester, Norwalk, Bridgeport, Naugatuck, Waterbury, Winsted, and Great Barrington. Entering Norwalk we had an interesting experience. Mrs. Macfarland and myself rarely care to exceed 15 miles an hour when autoing. This we find insures that health-giving ease and comfort which is the primary object of all our automobiling. Moreover, when we bowl leisurely along we can see and enjoy the scenery.

Unnecessary to Monopolize the Road.

We had begun to climb the steep hill just before entering Westport avenue at about a 15-mile per hour clip, when suddenly our attention was arrested from the rear by an impatient "honk! honk!" We looked back and found that it was a big foreign car belching at a terrific rate. I steered slightly to the right and permitted it to pass us. Presently the burly leviathan lessened its speed in a marked degree, while our little Reo kept on gathering velocity. The road widened and permitted us to repass the bigger car, much to the chagrin of our erstwhile pompous friends. By this time the sporting elements in both Mrs. Macfarland and myself were on their mettle. We vowed to eat no more of their dust. I quickly opened the throttle and advanced the spark, and it was not long before we were a comfortable distance ahead. We did not relish the idea of being approached impatiently from the rear with a "get-off-the-earth" look and act, merely because our car happened to be a little smaller. So we probably exceeded the speed limit a trifle on that hill, not because we were speed-omaniacs, but because, in a measure, we were forced to assert the touring rights, privileges, and courtesies which fellow tourists owe to one another, and particularly where there are ladies.

We arrived at Waterbury, a distance of 77 miles, at 10.30 A. M., where we had our second breakfast. The roads were excellent, barring some long stretches of sand and steep hills near Thomaston and Winsted. Thoroughly refreshed and eager to press forward on our second day after a good night's rest, we headed for Manchester, Vt., a distance of 71 miles, via Lenox, Pittsfield and Williamston. Steep hills and many stiff water-breaks were the incidents of the day's run. These had no terror at all for us, for with the rational wheelbase in our Reo, and its rear seat detached and replaced by a luggage hamper, we swept over the mountain tops with ease, our delight augmented by the beautiful country and the charms of perfect midsummer weather. It was on this day's run that we saw the Bennington battle monument, which was dedicated August 19, 1891, in commemoration of the victory won by a force of the New Hampshire militia under General Stark against Colonel Haum and a detachment of Burgoyne's army, August 16, 1777.

On this day we encountered a pelting hailstorm near South Shaftsbury, Vt, about 23 miles south of Manchester. Having no top on our car and being protected only by rubber ponchos, which, by the way, proved difficult for Mrs. Macfarland to don without seriously disarrranging her hair, we were urged by the gallantly disposed town clerk, who ran out from his veranda, to come in out of the storm. Needless to say we gladly accepted the kindly hospitality. During the lull of the storm we asked a native veteran of the Mexican and Civil Wars, whose silvery locks indicated at least one hundred rugged Vermont Winters, to take a ride in our car. But he refused, saying, "I am afraid of tbose gol-durned things, where I never wuz skeered of whistling bullets."

Young New Englanders Enthusiastic Autoists.

That an enthusiastic interest in autoing is borne by the younger generation in this mountain-locked hamlet was shown in the case of a prominent young man of the village. Not long ago he had to undergo an operation for a serious case of appendicitis contrary to his wishes. But there was no alternative. His father promised to do anything for him he chose, upon condition that he would submit to the ordeal. His choice was an automobile. He recovered, and to-day he is the envy of many a neighboring rugged Green Mountain boy.

The storm lasted the greater part of the afternoon, during which time we were regaled by the village gossip. Eventually the storm subsided, after which we continued on our way.

We were accorded uniform courtesy wherever we went. Everywhere the natives evidently were enjoying the fruits of their intelligence, thrift, and industry. Scarcely a hotel but what the progressive and prosperous farmer was well represented. One instance at the Bennington hotel will illustrate the usual run of our experiences. Here we dined at the same table in company with a genial couple, about seventy years young. Tbe husband wore a close-trimmed gray beard, and withal was sleek from the crown of his head to the sole of his feet. He seemed to belong to the old blue-blooded stock that has made the Granite State famous. His wife was one of those motherly dames, who mellow with age and whose eyes, instead of growing dim with advancing age, seem to gain lustre and conviviality. "I beg your pardon," said she to Mrs. Macfarland, with that freedom and ease that is born of true culture and hospitality, "may I ask you whence you hail from and where you are going?" After being duly informed, she then apologetically said, "I was specially interested, for you resemble my grandniece so much." Incidentally, Mrs. Macfarland then, too, noticed that her silvery-haired but blithesome questioner favored her own grand aunt. Then analyzing the radiant physiognomy of the elder lady's sterner half, Mrs. Macfarland thought she traced a strong hint of resemblance between him and myself.

I might go on indefinitely in this manner throughout our entire trip, but time and space forbid. Suffice it to say that a more intelligent and more hospitable folk never lived than those we came in personal contact with among the rugged mountain fastnesses of Maine, New Hampshire and Vermont.

And the wild raspberries and blackberries. Millions upon millions of them we found in endless procession. And what

luscious monsters! Just ripe enough to drop at the slightest touch. Frequently we paused to satisfy our ravenous craving and then with regret we would leave some of the better patches to fade away with the advent of Autumn leaves. To come so close to the big and generous heart of Mother Nature and to revel in her redolent and prodigal bounty certainly should bring joy and health to any sane and healthy man and woman and make him and her a better, nobler and happier American citizen than ever before.

The run from Manchester to Sunapee Lake, N. H., was 75 miles, made up in the good dirt roads and enough steep hills and water bars to lend zest to the tourist who enjoys an occasional sprinkling of the strenuous. Climbing Peru Mountain was exhilarating. The ascent was as a giant beside a pigmy when compared with the famous Jacob's Ladder of the Berkshires.

When reaching Simonsville, near Springfield, Vt., shortly before noon Mrs. Macfarland complained of a severe headache. This she attributed largely to the rich viands which she had partaken of in the various good hostelries at which we had stayed along our route. She longed for a light homemade luncheon. Presently we were directed to a motherly lady, who had a local reputation for dispensing luscious viands for weary and dust-begrimed motorists. Soon we were served a most delicious plain omelet, hot tea, hot biscuits, and wild raspberries and cream, the equal of which we had never relished before. It so thoroughly rejuvenated us that the drive from there to Sunapee Lake proved one of the pleasantest runs of our entire trip, and that is saying a great deal.

An Ever-Changing Panorama of Scenery.

Wednesday we covered the picturesque and mountainous run of 91 miles to Bretton Woods, via Bristol, Plymouth, and Woodstock over the White Mountains. After staying a day at Bretton Woods, we were ready to make our sixth day's run, an 82 mile jaunt to Poland Springs, Me. This we covered in about 5½ hours actual running time. Charmed by the grand view of valleys and mountains, and reveling in the glorous ozone of this popular resort, we yielded to the temptation to remain there Saturday and Sunday. Monday our route lay via Portland, Biddeford, and Portsmouth to New Castle, a distance of 81 miles. Apart from some occasional sandy stretches and some rough stony places, the roads were good through a rolling country. On our seventh day's run, we journeyed along the picturesque New England coast and enjoyed the Atlantic breezes for a stretch of 70 miles, our way leading through Hampton, Newburyport, Beverly, and Lynn, to Boston. Here we spent a week with relations and friends, making various tours within a radius of 75 miles of the Hub. From Boston we bowled happily to Providence and Newport, spending two days at fashion's summer capitol. The next attraction was Narragansett Pier, delightfully situated near the mouth of Narragansett Bay. Here we visited the scene of General Winslow's victory in December, 1675, when, at the head of 1,000 colonists, he defeated the Narragansett Indians, of whom 300 were killed and about 600 captured, while the whites lost 80 killed and 150 wounded.

New London, via Westerly, was our next objective point, the distance of 65 miles being comfortably covered. Having found the driving along the Long Island sound delightful on the day previous, we selected for our last day's run from New England to Mount Vernon, a route that took us through New Haven, Bridgeport, and Norwalk. At Mount Vernon our delightful 1,500-mile motoring tour came to an end, without the slightest mishap to ourselves or to our car.

I feel specially elated over our successful tour. At the completion of this trip I had driven my car 8,700 miles during the past two seasons. Not one cent has yet been paid for replacements. When I consider that I have negotiated the sandiest, roughest and muddiest roads and climbed the steepest hills in nine different States with such a splendid record of durability and reliability, it certainly testifies eloquently to the scientific design and superior construction of the car. It has proven perfectly adapted to all road and weather conditions. Never has its power and efficiency failed me. This has been largely due to the ample provision which has been made for lubrication—one of the principal sources of the life, power and smooth-running qualities of any car. Its axles are still in as perfect alignment as the day I bought it, while its springs, radiator and motor are likewise in similar condition. Automobiling under these conditions certainly is delightful and invigorating and within the reach of almost every man who now uses a horse and buggy.

Being only an amateur autoist and having accomplished what I have, I feel that others can do likewise. It certainly is worth the attempt. It should inspire many to do more. No steam locomotive has ever shown greater endurance, reliability and efficiency than did our little Reo. Americans may well feel proud of their automobile engineers and builders, who thoroughly know our rough roads and build and design their cars to successfully meet the strenuous conditions.

A SUMMER TRIP WORTHY OF NOTE.

MEMPHIS, TENN., Sept. 14.—What was probably one of the longest trips of the year has just been completed by one of this city's prominent automobile owners—Albert S. Caldwell—and his two friends, J. M. Folkes and Jack Carey. The party on leaving Memphis first proceeded to Nashville, crossing the Cumberland divide and on to Louisville, Pittsburg, Washington, Philadelphia, New York, Boston and many other cities in the East. They started on the homeward journey from the White Mountains, coming by way of Albany, Buffalo and along Lake Erie to Cleveland and Detroit, from there to Indianapolis and Louisville, where the machine, a six-cylinder Pierce, was shipped home by boat.

The Daimler Company's business year at Unterturkheim, closing on March 31, 1908, was hardly as profitable a one as that of 1906-07, and the financial crisis has also left its traces on the firm that manufactures the Mercedes vehicle. The net profit was 477,437 marks as against 1,505,840 marks of the previous year. A dividend of 6 per cent. will once more be paid.

In the Restful Quiet of One of New England's Shady Roads.

ACHIEVEMENTS OF THE WRIGHT BROTHERS.

One day, no one knows how many thousands of years ago, some cave-man or tree-man discovered that a log floating in the river would bear his weight, and that he could move it by paddling with his hands. No telegraph, no printing press spread the story of his achievement abroad; only a group of his tribesfolk looked on, amazed and fearful, as he slowly made his way across the stream. To them it was a miracle. But they did not understand the significance of this first uncertain voyage; their knowledge furnished no scale by which to reckon its importance. Even the next step of development, the dugout canoe, was beyond the bounds of their imagination.

To-day we accept the *Lusitania* and the *Dreadnaught* with hardly a second thought; and to-day the Wright brothers are flying at Washington and at Le Mans. Man is beginning the conquest of a new element. True, for more than a hundred years it has been possible to ascend into the air by means of balloons; but the limitations of the balloon as a method of transportation have been obvious from the first. The short, gliding flights of Lilienthal may be likened to the first venture of the prehistoric discoverer upon the floating log. But for his untimely death, Lilienthal might also have made the application of mechanical power; as it was, the Wrights received the benefit of his experience, and to them belongs the credit of building the first real flying machine. The thousands of curious spectators who daily flock to see them witness the beginnings of a new period in human progress.

The most sceptical cannot doubt that the Wright machine really solves the problem of mechanical flight. A machine that has repeatedly sustained itself and an operator at a height of from 100 to 200 feet for an hour must be regarded as more than a mere toy. Moreover, it is strong, reliable and marvelously simple. So far, the only objection that can be found is the extraordinary degree of skill necessary to operate it successfully. The aviator must cultivate a sense of equilibrium many times more delicate than that of a bicyclist, and must control almost instantaneously a complicated system of levers. Birds balance themselves instinctively in the most abrupt and violent air currents; man can acquire this ability only imperfectly. Some automatic device, then, must be invented to take care of this function. When this is done—a trifle compared to difficulties already overcome—the aeroplane will be a practical conveyance.

As to the future of the flying machine, it is useless to speculate. Apparently there is no reason why it should not be capable of as great development as the cave-man's floating log, although this must of course be the work of many centuries. But, however rude and clumsy the present machines may appear in the light of future developments, they have nevertheless demonstrated beyond cavil the possibility of mechanical flight, and the Wright brothers deserve the credit therefor. Their names will look well beside those of many other American inventors who have worked for the good of all mankind.

* * *

IMPORTANCE OF MOTOR TIMING.

Familiarity may well be said to breed respect where the internal combustion motor is concerned, for the more one comes to know of it the more one must marvel at the adverse conditions under which it will continue to operate. Of these, probably the most common is faulty timing, and experience with a large number of motors serves to bring to light the fact that the possible range of valve operation and ignition is extremely wide indeed. That the motor may be made to work at all at either of the extremes of this range seems impossible at first sight, and herein lies the anomaly, as the two motors representing the greatest difference may often be found to give an equally satisfactory performance.

It will be apparent that the proper opening and closing of the valves is of vital importance to the operation of the four-cycle motor, as with the present high speeds now favored, it has at best a very small fraction of a second in which to complete each one of the phases of its cycle and any overlapping one way or another is bound to derange it. This was a matter that came in for all too little attention in earlier days, but its importance has become better realized since and it is now customary to index the flywheel, so that the timing of the valve mechanism may not only be checked up, when trouble due to this cause is suspected, but so that it may also be corrected when it is no longer what the designer intended it should be. Probably faulty timing is accountable for a very large percentage of the ills to which old motors are heir, and if more attention were given to this essential by the average repairman it would be an advantage to all concerned.

A. A. A. AND A. C. A. REACH HARMONIOUS AGREEMENT

COMMITTEES named by the American Automobile Association and Automobile Club of America to effect a settlement of their differences reached a basis of agreement several days ago, and the board of governors of the Automobile Club of America ratified the agreement at its last formal meeting. On Monday of this week the executive committee of the A. A. A. met to consider the plan, but failing to reach an agreement adjourned until Wednesday. After a protracted meeting the committee formally ratified the agreement, and the understanding arrived at formally disposes of the controversy and establishes friendly relations between the two bodies. Secretary F. H. Elliott of the American Automobile Association has issued the following official statement covering the main points:

It is agreed that the Automobile Club of America is the only American member of the International Association of Recognized Automobile Clubs, and that it is and shall be the only authority in America for the drafting of rules affecting and for the granting of sanctions for international races, and for the regulation of such races in this country. On the other hand, the matter of the sanction of and the formulation of rules for local and national races is agreed to be, as heretofore, in the sole power and jurisdiction of the association. The two bodies agree to cooperate with each other in making the Vanderbilt Cup race and the Savannah Grand Prize race successes. After the races of this year the two cups are to be deeded to an independent racing association, and are to be contested for annually, the Grand Prize Cup as the International trophy and the Vanderbilt Cup as the National trophy. It is also agreed that the club shall not encourage other clubs to withdraw from the American Automobile Association.

The essential points at issue between the two organizations have thus been settled, and their cooperation in the future in all matters relating to the sport of automobile racing is assured.

PENNSYLVANIANS, WELL ORGANIZED, TO AID AUTOING

PHILADELPHIA, Sept. 14.—Upwards of a score of automobile enthusiasts, including the executive committee of the Pennsylvania Motor Federation and the presidents of several of the clubs from towns in the eastern section of the State, gathered at the handsome home of the Automobile Club of Germantown last Friday morning to discuss ways and means of improving automobiling conditions in the Keystone State. It had been the original idea to wind up the business of the meeting in two or three hours, but the session developed so much of importance to the welfare of motorists generally that the motion to adjourn was not put till nightfall, and then the Germantown hosts insisted on all hands "staying to tea," although a bountiful lunch had been set for the guests at midday. As a result the meeting continued informally well into the night.

Besides Robert P. Hooper, of this City; Vice-President Peter A. Meixel, of Wilkes-Barre, and Secretary Paul A. Wolff, of Pittsburgh, there were present: State Senator Frederick A. Godcharles, of Milton; President Joseph A. Weeks, of the Automobile Club of Delaware County; President Powell Evans, of the Automobile Club of Philadelphia; President P. D. Folwell, of the Quaker City Motor Club; President John Burd, of the Delaware State Automobile Association; John A. Wilson, Franklin; Martin Kinports, Lancaster; Dr. J. F. Kleindinst, York; Dr. W. H. Stephens and Lyman H. Howe, Wilkes-Barre; J. Madison Porter, Easton; John G. Kugler, Pottstown; John H. Rex, Norristown; Joseph Bancroft, Wilmington, Del., and S. Boyer Davis, L. P. Baekey, chairman of the federation's committee of publicity; C. H. Wheeler, Mark B. Reeves, Stephen B. Ferguson and a dozen other Philadelphians were in attendance.

President Hooper's report was especially strong in its insistence that something should be done to keep the scorcher and road-hog automobilist within bounds, and he urged that the federation take drastic action on those who use highways as race courses.

Another feature of President Hooper's report—the necessity of increasing the membership—brought immediate action. After a thorough discussion of the matter the president was authorized to appoint a committee to organize automobile clubs in all sections of the State where there are a sufficient number of motorists to warrant such a course. Secretary Paul A. Wolff, of Pittsburgh, was named as chairman of this committee, which was ordered to get to work at once. One would imagine from the foregoing action that the recruiting work of the federation was lagging. Such is not the case, for immediately following the appointment of the committee no less than eight new automobile associations were admitted to membership. They are: Monroe County Automobile Association, Automobile Club of Lawrence County, Johnstown Automobile Club, Automobile Association of Scranton, Automobile Club of Franklin, York County Automobile Club, Pottstown Automobile Club and the Oil City Automobile Club. These additions bring the total number of organizations in the federation above the thirty mark.

After lunch S. Boyer Davis, of the legal committee of the Automobile Club of Philadelphia, read the rough drafts of a new State automobile law and a proposed new measure to govern the building and maintenance of roads, to be presented at the next meeting of the Legislature at Harrisburg in January.

AUTO ENGINEERS MEET IN CLEVELAND THIS WEEK

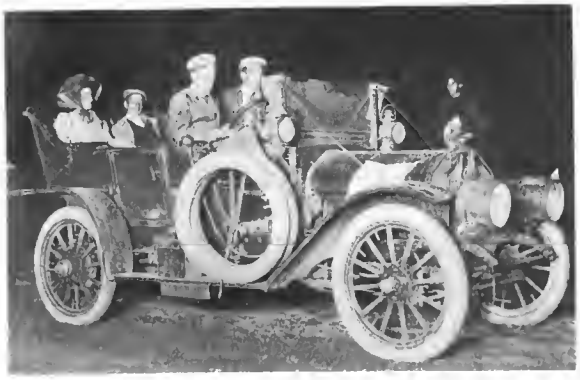
CLEVELAND, Sept. 14.—The Society of Automobile Engineers is to meet at Cleveland Thursday next for its third quarterly meeting of the present year, and the prospects are that there will be quite a number of members in attendance, as the strength of the society in the Middle West is rapidly on the increase. The morning of the first day, Friday, will be devoted to visiting a number of the automobile manufacturing plants which give Cleveland its important position in the industry, among them being the Stearns, White, Winton and Peerless, as well as some of the parts-making plants, such as that of the Hydraulic Pressed Steel Company.

The business meeting will be opened at the Hollenden after lunch and will be followed by the technical sessions, the latter also being continued after dinner in the evening. Saturday morning a special train will be boarded at the Union Depot for the trip to Akron, where the morning will be spent in making visits of inspection to the plants of the Goodrich and Diamond rubber companies, the society being the guest of the latter at a lunch to be held at the Akron Country Club. Following this the engineers will go to Canton, where they will inspect the plant of the Timken Roller-Bearing Axle Company as guests of the latter.

Arrangements are in charge of a local committee consisting of James G. Sterling, chief engineer of the Stearns company; F. B. Stearns, Harold B. Anderson, chief engineer of the Winton company, and H. W. Alden, of the Timken company, Canton. The papers scheduled for the meeting are: "The Limitations of the Universal Joint," by H. Vanderbeek; "What Carbon Does to Automobile Steel," by Thomas J. Fay, president of the society, and "What is the Best Timing?" by Louis Lacoin, a translation from the French of *Omnia*, by Charles B. Hayward.

EIGHT OUT OF FIFTEEN PERFECT IN OHIO RUN

TOLEDO, Sept. 12.—Toledo's first endurance run, organized and carried to a successful close under the auspices of the *Toledo* Times, the Toledo Automobile Club, and local automobile dealers, ended Thursday evening of this week. Out of fifteen cars which made the run, eight finished with perfect scores, with the probability that another perfect score will be added to the list after the matter has been taken up by the technical board of the A. A. A.



Mora Confetti Car Leaving Columbus Second Day.

The route of the run consisted of approximately 600 miles, roughly of triangular form. Starting from Toledo, the pilot car steered through Findlay and Marion to Columbus, which consisted of the first leg. The second day's run lay from Columbus, through Mansfield, Wooster and Akron to Cleveland, and the third and closing day comprised a circuitous route from Cleveland to Toledo. Lack of rain made the road fearfully dusty, and most of the penalties imposed were due to accidents or delays occasioned by dust and dirt playing havoc with the machinery. Nor was the route selected without idea or thought for the behavior of cars on steep and difficult hills. Few parts of Ohio contain more difficult hills for climbing than Holmes County, through a part of which the route lay. Luckily, however, no serious disasters resulted, although a few mishaps served to show the metal of the drivers.

The entrants, seventeen in number, two of which withdrew before the race started, were divided into two classes, amateurs and professionals, there being two of the former and thirteen of the latter. Of the professionals, twelve finished, the Maxwell, driven by Weger, being withdrawn, and of the amateurs, one, the Stoddard-Dayton, driven by Spieker, having fallen by the wayside on the first day's run through the loss of a wheel, occasioned by colliding with a farmer's wagon.

The result of the run as it stands at present is as follows:

Car.	Driver.	Standing.
Mora	Adams	1,000
Jackson	Schetfler	1,000
Jackson	Paxon	1,000
Brush	Huss	1,000
Reo	Adams	1,000
White	Phillips	1,000
Oldsmobile	Auble	1,000
Oldsmobile	Torgler	1,000
Mitchell	McIntyre	973
Chalmers-Detroit	Gamble	973
Maxwell Model H 2-cylinder	Bitesdale	705
Maxwell Model D 4-cylinder	Kelsey	542
Stoddard-Dayton	Atwood	No decision.

Of the standing, it may be said that possibly some changes will be made by the A. A. A. board, as certain features are to be referred to it for final decision; for example, the Stoddard-Dayton, driven by Atwood. It is reasonably certain that when this car was left in a Columbus garage for the night it was in perfect condition, but it was found to be damaged in the morning when it came to checking out, the damage, it is alleged, being due to careless handling on the part of the garage attaches. There is a disposition on the part of the officials of this run to allow Mr. Atwood a perfect score, in so far as his trouble in that respect is concerned.

Of the other losses, Kelsey was given on the first day 137 points, by reason of loss of time spent working over gasoline tubes which had become clogged with dirt. On the second day he lost 132 points for spark ptug trouble. McIntyre lost 27 points for the same reason. Bliesdale lost 295 points when his steering gear rod broke, as the result of hitting a large boulder. Weger was here entirely elimmated, by reason of spark trouble which caused his engine to overheat. On the third day Gamble lost 27 points for running into Sandusky a few minutes behind time, and Kelsey ran into his third dose of trouble by losing 189 points for a broken spring.

In point of interest and endurance, the second day was undoubtedly the best test of the run and brought out several notable incidents as the result. The trouble at Columbus, mention of which has been made, caused Atwood to leave the city a long time after schedule, with temporary repairs which allowed him to only use high speed gears, and this over that part of the trip which had been selected on account of the high and steep hills. Hill after hill was encountered and climbed in this unusual way, and Mr. Atwood reached Cleveland late in the evening.

Another incident happened to Bliesdale while going through the Holmes County hills. Descending one, his car skidded, and in so doing struck a stone, which carried away the steering arm. Apparently helpless, Bliesdale surmounted the situation by cutting a young tree with his pocket knife, fitting it to take the place of the broken part, and finishing the rest of the trip with this as a steering arm.

By reason of finishing with a perfect score, E. R. Torgler, of this city, wins the handsome cup set up for the best amateur record by the Toledo *Times*. Mr. Torgler's work was such as to call forth much admiration and the opinion from his fellow-sportsmen that he ought to be in the professional class. As mementos, the committee having it in charge will probably provide some kind of silver badges or medals, although the exact nature of which has not yet been determined.

Kelsey and His Maxwell Making Up Lost Time.

The officials likewise won the entire confidence and appreciation of the entrants by the just and reasonable decisions and fairness in all particulars. R. K. Davis, of the Maxwell-Briscoe-McCloud Company, of Detroit, was referee, and P. W. Eigner, of the Pope-Waverly Company, Indianapolis; H. H. Howard, of the Cleveland *Plain Dealer*, and M. M. Norton, of the Toledo office of the Goodyear Tire & Rubber Company, were the assisting officials. A Pope-Toledo car piloted the run, the rules governing which were customary to such events.

HOW THE CLUBS ARE

A. C. OF CALIFORNIA IS BUSY SIGN-POSTING.

SAN FRANCISCO, Sept. 12.—The Automobile Club of California, rue to its promises of a few months ago, has commenced the splendid work of what will be a monument to their organization, the erection of sign-posts. After several months of careful study and investigation of different methods of such an achievement, maps have been completed, posts made and signs

California Club Officials Placing the First Sign Post.

ameled and yesterday Samuel G. Buckbee, president of the ıb, and L. P. Lowe, chairman of the executive committee and esident of the California State Automobile Association, surintended the placing of the first post. A large gathering of al enthusiasts assembled at the scene, which was located at corner of Nineteenth avenue and Parkside boulevard, to witss the event, and to express their appreciation for the great od that will be forthcoming. The posts are iron, and are ostantially sunk in the ground about two feet deep, in cement ındations. Through the bottom of the posts, set in the nent, are twelve-inch iron rods.

The club will continue the erection of signs until the country well-posted north of the section which is being ably taken e of by the Automobile Club of Southern California. Then, rk will be taken up on the roads leading out of Sausalito, ıuron and Oakland, until the entire State is posted. Routes e been laid out as far as Lake Tahoe. Hearty congratulaıs were extended to President Buckbee and Chairman Lowe, be conveyed to the members of the club, on the commencent of this good work, and there is little doubt but that now t the ball has started to roll, the Automobile Club of Calinia will receive strong co-operation from the other local omobile organizations and enthusiasts.

CCESS OF KANSAS ENDURANCE RUN ASSURED.

ANSAS CITY, Mo., Sept. 14.—Every indication now points to success of the fall endurance run of the Automobile Club, of nsas City, which starts Saturday morning, Sept. 19, from ın Valley Park for Oklahoma City via Emporia and Wichita, ırning to this city via Guthrie and Winfield. The finish will n front of the *Star* office on Grand Avenue, as this paper has red a cup to the winner. The total mileage will foot up to r 920 miles, and it is fully expected that this run will prove as essful as similar tours have in the East. Indications are about forty machines will start, and, under the comparatively ent rules that have been made, more than half of the starters ıld finish with perfect scores. It was at first proposed to a strict system of penalization, but this was voted down, and s present form the tour should be enjoyable as well as inctive to every one of the participants.

SOME SELDEN LITIGATION NEARER HOME.

Following the meeting of the managers of the Association of Licensed Automobile Manufacturers, held in New York City early in the month, a report has grown that the session was not devoted entirely to the consideration of the ordinary routine business of the association, but that drastic action was taken with regard to two members who have been delinquent in their royalty payments. These are the Olds and Buick companies, and it is said that they have made no payments for nine months. Also that an action will be instituted to cancel the license of the Olds Motor Works, which is one of the original founders of the association, a similar move apparently not being contemplated in the case of the Buick at present. That there is some foundation for the report seems evident from the omission of the two concerns in question from the space allotments for the Garden show next Winter. When seen regarding the story Assistant-General Manager Chalfant said "There's a litttle truth and a great deal of fiction in it," but refrained from furtber comment.

CONNECTICUT CLUBS ON RIGHT TRACK.

HARTFORD, CONN., Sept. 14.—The Connecticut Automobile Association through the recently organized Torrington Club has gained 20 more members. Tbe more the merrier, for tbey will all be needed this Winter. A certain antagonistic faction has been keeping count of every automobile muddle that has happened this season for presentation to the lawmakers this Winter. However, the recent appeal of the Automobile Club of Hartford and of the State Association to automobile owners to respect the Connecticut law has not been without its good results. A careful survey of the situation reveals the fact that where there is opposition the party in question usually has a grievance, caused in many instances by the indiscretion of some lawless chap.

24-HOUR RUN OF BAY STATERS.

BOSTON, Sept. 12.—The touring committee of the Bay State Automobile Association, which has charge of the twenty-four hour Bretton Woods endurance run to be held September 23 and 24, went over the course a few days ago and as a result of its trip has announced some important changes. The committee found the roads in bad condition, so bad in fact that it decided that it would be unwise to send the cars through the mountains in a contest at night as originally proposed. Therefore instead of starting from Boston at ten o'clock in the morning, as previously announced, they will start at ten o'clock at night.

Another important change intended to make the contest safer is the use of controls at intermediate points, as well as observers and a pace maker. The pace making car will be accompanied by a member of the committee and will not be driven faster than the legal limit. Passing the pace maker disqualifies a contesting car. There will be controls at the start, at Rochester, N. H., at Bretton Woods, the turning point, and at Concord, N. H. on the way back, with a final control at Boston. Penalties will be inflicted for arrival at controls ahead of or behind time. The course is through Lynn and Salem to Newburyport, Portsmouth, Rochester, the Ossipees, Intervale, Crawford Notch to Bretton Woods, where an hour's stop will be made. On the return trip the cars will pass through Bethlehem, Franconia, Profile, Plymouth, Concord, Manchester, Nashua and Lowell.

NEW JERSEY A. C. SUMMONS E. R. THOMAS.

NEWARK, N. J., Sept. 21.—The trustees of the New Jersey Automobile and Motor Club at their last meeting passed a resolution censuring E. Russell Thomas, the New York banker, for his reckless driving, which resulted in the accident at Long Branch August 14. Continuing, the resolution summoned Mr. Thomas to appear before the board on the evening of October 5 to show reason why he should not be expelled from the club. Mr. Thomas is still confined in the hospital.

POSTER FOR THE PALACE SHOW.

The show committee of the American Motor Car Manufacturers' Association has made its selection of the pictorial posters for the Ninth International Automobile Show at Grand Central Palace, New York City, which opens on New Year's eve. It consists of a five-color drawing on big twenty-four sheet poster of a large red car shooting through an imaginary sky, leaving behind a trail of lurid yellow, giving the poster an unusual amount of life and action. On the yellow tail of the comet are printed in red the words Ninth International Automobile Show. The contract has been given to Seiter & Kappes to produce this as soon as possible. Besides this large poster the committee has artists at work on a smaller one to be in seven colors.

POPE REORGANIZATION WELL UNDER WAY.

HARTFORD, CONN., Sept. 14.—According to present indications, it now appears that the reorganization of the Pope Manufacturing Company will be consummated by November 1. The report of the receivers for August, recently filed with the Superior Court, shows the cash receipts to have been $54,943.66, disbursements $66,776.30, and the sales $43,041.12 during that month. To quote Albert L. Pope, one of the receivers: "The plan of reorganization is now assured of success and it will be completed within a very short time." The final proceeding of the receivers will be to apply to the courts for authority to sell the plant to the committee of reorganization.

ANNUAL MEETING YORK MOTOR CAR COMPANY.

YORK, PA., Sept. 14.—At the annual meeting of the York Motor Car Company, builders of the Pullman car, the stockholders elected the following officers: President, S. E. Bailey, Philadelphia; vice-president, T. C. O'Connor, New York; secretary and treasurer, Oscar Stevenson, New York; general manager, J. A. Kline, York, Pa. In addition to the above, the following stockholders were present at the meeting: J. C. Schutte, Lancaster; W. F. Lebzetter, Lancaster; John Smith, Lewiston, Me.; A. W. Sechrist, J. E. Crimins and Geo. F. Ryan, of York.

That the automobile trade is a good one was again evinced by the fact that the company was able to declare a 6 per cent. dividend on the $100,000 capitalization. That the business should be able to pay such a large dividend is a source of pride to the stockholders, who attribute the company's success to the efforts of General Manager J. A. Kline to produce a car suited to the public, and the ability of Sales Manager H. R. Averill to sell them. The Pullman line for 1909 has not yet been announced, but the cars which met with such favor this year will probably be continued with little change during the coming season.

HARTFORD TIRE BRANCH MANAGERS CONFER.

HARTFORD, CONN., Sept. 14.—During the early part of the week there was a three-day conference of all the branch managers and field representatives of the Hartford Rubber Works Company, in Hartford. They were all on hand Saturday, and Sunday were taken to New Haven and treated to a typical Connecticut shore dinner by Justus D. Anderson, president of the company. The party included M. C. Stokes, W. H. Reed, Vice-President H. E. Field, Treasurer Henry Plough and J. P. Krough. Two shifts of men have been constantly employed since April 1, and the branch managers have come to familiarize themselves with the plant and its workings. Those attending the conference from out of town were: C. H. Kenyon and A. H. Lowe, of Buffalo; H. F. Kesser, W. Barnes, E. H. Johnanson and F. W. Culver, Philadelphia; E. S. Roe, E. H. Fahy, Harry Snyder, A. D. Creedon and W. R. Brown, New York City; T. H. Wilkinson, Los Angeles; W. H. Bell, D. W. Shattuck, W. B. Powell, H. E. Smith, R. Sillies, J. F. Kerner and G. R. Noble, Chicago; C. Langmaid, S. D. Niles, W. P. Barth, Boston; H. C. Severence, J. J. Tompkins, Detroit, and H. P. Goodale, H. C. McIntosh, Cleveland.

CHALMERS-DETROIT AGENTS GIVE A JOY RIDE.

The Chalmers-Detroit was very happily and hospitably introduced to the New York newspaper men by President Page and General Manager Percy Owen, of Carl H. Page & Company, on Wednesday of last week. This metropolitan "coming out party" of the Chalmers-Detroit took the form of a joy ride with a luncheon as a wind-up. Seven cars made up of a Thomas "40," a "30" runabout and five "30" touring cars carried the thirty odd guests. The caravan ran out Broadway and over the boulevards in the neighborhood of Van Cortlandt Park, winding up the twenty mile run at the Abbey, a resort overlooking the Hudson, where luncheon was served without the boredom of speech-making, beyond a brief exchange of jollies between hosts and guests. After lunch the scribes spent a couple of hours very pleasantly on the lawn before they started on the jaunt home. The Chalmers-Detroit made good in the demonstration.

SELDEN PATENT PAYMENTS SMALL IN AUGUST.

HARTFORD, CONN., Sept. 14.—The report of the business done by the Electric Vehicle Company during the month of August has just been filed. It shows cash sales of $20,231 and purchases of $6,866.66. Of the cash receipts but $143.71 is credited to the Selden patent. The disbursements were $45,483.21, of which $28,002 was paid George B. Selden; cash on hand, $263,900.77.

Goodrich Army of Branch Managers, Salesmen and General Representatives.

These were gathered recently at Akron, O., when the B. F. Goodrich Rubber Company had its meeting, at which the policy for the coming year, reduction of prices and other matters of interest were discussed and decided upon.

White Steamer Trying Out a Stretch of the Vanderbilt Cup Course.

Stewart Speedometer Announcement.—The Stewart & Clark Manufacturing Company has been "sitting up nights with its eye on the 1909 season," according to its own admission, and promises one of the best propositions ever made in the accessory industry. No outsiders have as yet been let into the secret, but it will be made public within a few days. The Stewart & Clark Company has been specializing in flexible shafts for thirty years and operates what is claimed to be the largest factory in the world devoted to this line, that of the Chicago Flexible Shaft Company. Another exclusive feature of the 1909 line will, of course, be the Stewart swivel joint. The popularity of this instrument is attested by the enormously increased output during the last season; even in England it found immediate favor and became at once a dangerous competitor to the home product. Perhaps part of this success may be due to the five-year ironclad guarantee whicb has from the first covered all Stewart instruments.

Factory Dining Room.—The Geo. N. Pierce Company, of Buffalo, has put in operation a plan which it says is working admirably. On the top floor of the new office building the company has provided a dining room which has the capacity for seating 800 people at once. The workmen reach this room by passing through a tunnel from tbe shops and an elevator to the top floor. A large kitchen and ample help has been provided, and the men secure their dinner for a nominal sum with much less trouble than before. The officials of the company have a clubroom on the second floor of the building, where they gather for their midday meal. On the second floor will also be found light and roomy offices, reception room, library and other rooms. The basement bas been fitted up with locker rooms and wash rooms for the men.

The Pope-Waverly Makes a Record.—At the Indianapolis factory of the Pope-Waverly Company recently a test was wanted on one of the stock batteries for mileage and general service. A battery was installed in a stock car, Model 70B, and an office man was sent out with orders to run it down. He was given a definite route, selected for its average condition, and started from the factory at 1 o'clock. On his return at closing time he had covered 62 miles that day. The car was locked up where no one could meddle with it during the night, and the next morning he was again started out. When he next showed up he had covered a total of 142 miles and the car was still running smoothly, seemingly capable of at least five miles more.

Largest Industry in Syracuse.—The automobile business in Syracuse has increased so rapidly in the past few years that now the largest single industry in the city is the H. H. Franklin Manufacturing Company, having done a business of over $4,000,000 during the year ending Sept. 1. Of this amount brought to Syracuse by the Franklin Company a goodly percentage of it has been placed in circulation in wages to the 1,500 employees. What this does for the merchants of Syracuse is only one example of what the automobile industry is doing throughout the country for business in general, as this record of the Franklin is but one instance of many to be found in the American auto trade.

Pope Indianapolis Plant Sold.—No objection having been raised to the proposed sale of the Indianapolis plant of the Pope Motor Car Company, where the Pope Waverley electric vehicles have been manufactured, Vice Chancellor Howell, sitting at Newark, N. J., granted the necessary authority to consummate the sale. The consideration was $200,000 and it is understood to cover all the assets of the company, outside of the cash in bank, including all patents, copyrights and the like, a forfeit of $5,000 being deposited by the bidders, Herbert H. Rice and Wilbur C. Johnson.

Rambler Plant Growing.—Thomas B. Jeffery & Company is about to make the seventh annual addition to the Rambler factory at Kenosha, Wis. Ground has been broken for a concrete building, 257 by 150 feet, which will give an additional floor space of 38,500 square feet. The new building will be used by the final test department. Every year of the past seven has seen some large addition to what the Rambler people now claim is the largest automobile factory in the world. The latest photograph of the plant, below printed, shows its vast extent to a nicety.

A Winton Labor Day Tour.—A. S. Gilman, of Cleveland, drove his Winton Six from that city to Cambridge Springs, Pa., and back last Labor Day in ten hours' running time, without any attempt to make speed. The car carried ten passengers all the way. "I will certainly enter my car in the Winton prize contest this Fall," said Mr. Gilman. "I ought to have entered the first contest, and the car would have been a winner, too, for I have done 8,000 miles in it with practically no repair expense at all."

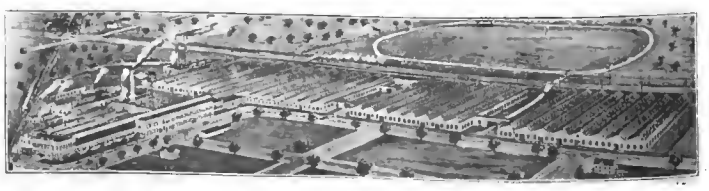
Hot Engine Club Toast.—From A. U. Jervis comes the following: "At a recent luncheon of the Hot Engine Club in New York the following toast was proposed: 'The good people of Savannah, Ga., and the good people of Lowell, Mass., let us drink to them and hope they will get all that is coming. Mr. Morrell has promised the good people of Savannah a race this year and he has promised the same race to the good people of Lowell for next year. God bless the good people; drink hearty.'"

New York's Newest Garage.—The Apthorp Garage, 214-216 West Eightieth street, at Broadway, was opened September 14 for the storage of private automobiles. The building is a modern structure, absolutely fireproof, six stories in height, and will be conducted on up-to-date principles and equipped with all the latest appliances for the comfort and convenience of automobile owners. The machine shop will be complete in every detail. Frederick Dickinson is in charge.

Walter Christie Automobile Company.—The latest recruit to the ranks of automobile manufacturers in this country has come forth in New York City under the above title. Tbis company has been formed with a capital of $400,000, and it proposes to manufacture motors, automobiles, carriages and trucks. Incorporators: Van S. Howard, C. Colgate Moore, G. W. Moore, Morris Gest, Louis P. Strang, Samuel Bogart, all of New York City, and J. B. Lozier.

Mora Motor Car Company.—The sealed bonnet Mora car which this company drove almost 8,000 miles without the hood being lifted has been sold to H. I. Buttery of Waterloo, N. Y., who decided that in buying a machine he wanted to feel that he was getting a car that has already proven itself worthy. The power plant was placed in one of tbe light-powered touring cars, and the reports from the owner so far indicate that the car is doing excellent work.

Increases Its Capital.—The Auto Body Company, of Lansing, Mich., has increased its capital stock from $25,000 to $150,000, the increase all being subscribed for by the present holders. According to Secretary Bradner, the sole reason is the rapidly growing business of the company, whicb greatly added to its capacity during the past year by new buildings and equipment.



The Big Factory at Kenosha, Wis., Where Ramblers Ars Made.

Stearns Changes.—The F. B. Stearns Company, of Cleveland, has made an announcement which will be a surprise to many. They propose that within sixty days they will be able to give purchasers of the Stearns cars the option of either the shaft drive or a chain drive. The company and sales manager, Charles B. Shanks, still prefer the chain drive, but they realize that all others do not, and to meet the demand have undertaken this policy.

Truffault-Hartfords at Lowell. — In speaking of the mechanical constitutions of the cars which participated in the 250-mile road race at Lowell, Mass., on Labor Day, mention was made of the fact that the Simplex, No. 1, was equipped with Truffault-Hartford shock absorbers, but the fact that the winning Isotta, driven by Strang, as well as the No. 2 Fiat, handled by George Robertson, were also similarly equipped was overlooked.

Another Sign of Prosperity.—The Speedwell Motor Car Company, of Dayton, O., has started work on the foundations of another new building 50 feet by 150 feet. This is the ninth building to be erected under the administration of General Sales Manager Loomis, who states that over half the product for 1909 has been contracted for. If this company keeps on, it bids fair to be one of Dayton's largest industries.

White Wins in South Carolina.—Columbia, S. C., had its first automobile race meet Labor Day on the mile track at the fair grounds, with over 2,000 people present. The principal event, the 25-mile free-for-all, for the Board of Trade cup, was won by a 30 horsepower White Steamer, driven by R. D. Lambert, his time being 30 minutes 30 seconds.

Avery Gas Company Moves.—The Avery Portable Lighting Company, maker of Avery gas tanks, has moved its general offices and sales department from 18-20 Martin street to 461 Broadway, Milwaukee, Wis. The factory will remain at the Martin street location until the new plant now under construction is completed.

De Palma Used Continentals.—When Ralph de Palma drove his Fiat to the new one-mile world's circular track record at Minneapolis, September 5, he used Continentals. His mark of 51 seconds is likely to stand for some time.

IN AND ABOUT THE AGENCIES.

Cadillac.—The Cadillac Motor Car Company, Detroit, Mich., has made preparations for the removal of its local branch in that city from 256 Jefferson avenue to 1403 Woodward avenue.

Schacht.—B. Applegate & Company, 326 Broad street, Philadelphia, have just been appointed agents for the Invincible Schacht high-wheel runabout in the Quaker City and adjacent territory.

Elmore.—The new Elmore agency garage, which is to be built at 742 South Olive street, Los Angeles, Cal., is now in course of construction. It will house a salesroom, garage, repair shop and office.

Gove Automobile Company.—Wisconsin State agents for the Regal, and which also has the agency for the Jackson and the Brush cars, has just moved into its new establishment at 52-56 Biddle street, Milwaukee.

Premier.—Webb Jay has just been appointed local agent in Chicago for the Premier car, made by the Premier Motor Manufacturing Company, Indianapolis, Ind. Until recently the Walden W. Shaw Company was the exclusive agent for the Premier.

Oldsmobile.—The Oldsmobile Company, of New York, has leased the building at 251-253 West Fifty-eighth street, and will have it altered into a garage at a cost of $30,000. Plans have already been drawn by Cowen & Company and work will be begun at once.

Stevens-Duryea. — The Tufts-Justin Company, which was recently appointed local agents for the Stevens-Duryea cars in Providence, R. I., to succeed the Snow Automobile Company, will remove into new quarters in the Dutee Wilcox Building at Aborn and Washington streets as soon as alterations are completed.

Monarch Motor Car Company.—Word comes from Chicago that the Monarch Company has just established three new agencies as follows: J. E. Garnett, Kan., with headquarters at Wichita; G. Ludemann, Northeastern Iowa, headquarters at Parkersburg; H. M. Martinstein, Colorado, headquarters at Denver.

Chalmers-Detroit.—The Chalmers-Detroit car will be handled in Baltimore by the Zell Motor Car Company. This company, only recently organized, has E. Stanley Zell, former secretary of the Motor Car Company of this city, as president of the new firm. They have opened up temporary quarters at 1010 Morton street.

Stewart Speedometers.—Word comes from Chicago that the Stewart & Clark Mfg. Co., of that city, has established its New York office in the Motor Mart Building, 1878 Broadway. On the first floor a complete line of Stewart instruments will be on hand at all times, while basement facilities have been provided for making any adjustments or for installing instruments.

F. B. Stearns & Company.—Although the Stearns Company has been doing an increasing business for years, this does not seem to satisfy the new sales manager, Chas. B. Shanks. Heretofore almost the entire Stearns output has been disposed of in the East, but the few cars that this company has sold west of the Mississippi have been so well received that Mr. Shanks has started on a tour of the West to stir up all the Stearns agents to renewed activity. In anticipation of the growing demand for Stearns machines the company is making extensive additions to their Cleveland plant, both in floor space and machinery. The present plant has been working to its full capacity for two years with both a day and night shift, so means for increasing the force of men was the only means of enlarging their output.

PERSONAL TRADE MENTION.

Curtis W. Betts, formerly on the sales staff of the Mitchell Motor Car Company, of Racine, Wis., has joined the forces of the Peerless Motor Car Company, Cleveland, O.

W. W. Taxis, who has been with the New York office of the White Company, and well known to the automobile trade, has been appointed manager for the company in East Orange, N. J.

F. C. King, who was formerly connected with the F. B. Stearns Company, Cleveland, O., has been appointed manager of the repair department of the Metropolitan Motor Car Company of the same city.

Leon Rubay, well known to the automobile trade as an importer of foreign sundries, has taken charge of the wholesale department of Rothschild & Company, 530 West Twenty-seventh street New York City, builders of auto bodies.

C. D. Snow, formerly head of the Snow Automobile Company, Providence, R. I., is now connected with the American Locomotive Automobile Company at its Providence selling branch. Mr. Snow had the Stevens-Duryea agency in Providence for six years

B. F. Adams, who has been acting as manager for Carl H. Page & Company, agents for the Peerless, in Newark, N. J., has severed his connection with that concern to go with the Ellis Motor Car Company. Mr. Adams was with the White Company formerly.

R. M. Daniels, manager of the Studebaker branch in Boston, will in future also look after the interests of the new E-M-F car in that territory, under the terms of the recent agreement between the E-M-F and the Studebaker companies by which the latter is to market half the product.

The Men Who Sell Chalmers-Detroits in New York

President Carl Page (at wheel) and General Manager Percy Owen of Carl H. Page & Co.

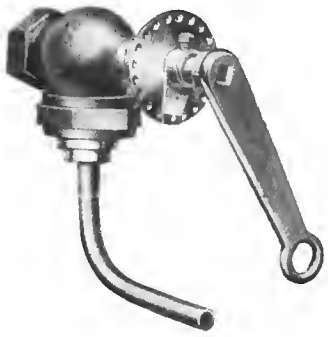
George H. Strout, the sales manager of the Apperson Brothers Automobile Company, left Kokomo Sept. 11 on his annual trip to the Pacific Coast in the interests of the company. He will visit the principal cities in Colorado, Utah, California, Oregon, Washington, Montana, Minnesota and Wisconsin before returning to the factory.

C. B. Warren, for the past five years associated with the Haynes Automobile Company, Kokomo, Ind., latterly as sales manager, has resigned, effective October 1, and will take charge of the Pacific Coast business of the F. B. Stearns Company, of Cleveland. The Stearns Company will open a branch in San Francisco with Mr. Warren in charge to supply the trade on the coast, Salt Lake City being the eastern limit of Mr. Warren's jurisdiction.

Frank Staley, president of the Indianapolis Automobile Trade Association, has disposed of his business interests in Indianapolis and will take an extended trip through the West. Mr. Staley has been with the H. T. Hearsey Vehicle Company for the past fourteen years, and for the last decade has been its vice-president and general manager. For many years the company handled carriages and bicycles, and later automobiles were added, this branch of the business having been largely developed by Staley. His interests have been taken over by Fred I. Willis.

INFORMATION FOR AUTO USERS

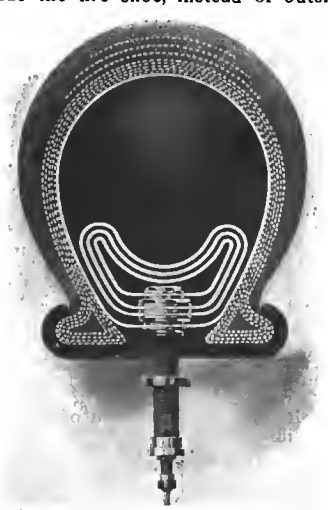
Indicator for Gas Tanks.—The Avery Portable Lighting Company, of Milwaukee, Wis., have recently put upon the market a little device for the users of gas tanks. It is a very simple arrangement which can be attached to all makes of tanks for regulating the amount of gas to turn on. As will be noticed in the



GRADUATED INDICATOR FOR VALVES.

accompanying illustration, there is a dial on which travels a pointer. This pointer is so made that it fits into any of the notches shown on the dial and gives a clicking sound when moved, so that at any time, day or night, the user may turn on the gas and know just how much he has opened the valve, two notches being plenty for two lights.

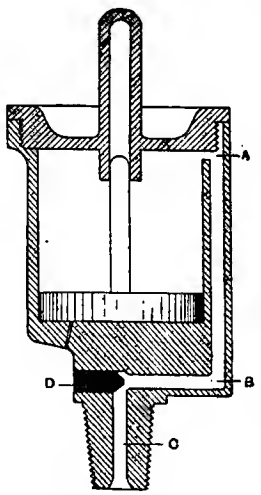
Guaranteed Faultless Inner Tube.—An ingenious solution of the tire problem appears in this product of the Guaranteed Faultless Auto Tube Company, 104 West Forty-second street, New York. The idea is that spare inner tubes should be carried inside the tire shoe, instead of outside,



"FAULTLESS" TUBE, ONE INFLATED.

thus obviating the necessity of removing the shoe whenever it is necessary to replace a punctured tube. The "Guaranteed Faultless" tube therefore consists of four tubes, one inside of the other, arranged so that each can be inflated in turn by rotating the valve stem a notch. When a tire is punctured all that is necessary is to give the valve stem a twist, connect the pump, and inflate the next tube. When all four tubes have been punctured—which should not happen for many thousand miles—the company will repair and vulcanize the tubes free of charge. The device promises to save much time and trouble in touring. The arrangement of the tubes and valves is clearly shown in the cut.

New Loose Pulley Oil Cup.—The accompanying cut shows a newly patented oil cup for use on loose pulleys. This device, made in two sizes, is manufactured by the Lawson Manufacturing Company, Buffalo, N. Y., and is claimed to solve the loose pulley problem, viz., keeping the loose pulley well oiled while in operation. It is the only cup of its kind on the market and should be a great saving, not only to the large number of manufacturing plants in the country, but to the increasing number of automobile



SECTION LAWSON OIL CUP.

owners who have had trouble keeping the clutch collar from heating.

The cup consists of three distinct parts: A body, piston or plunger, and an oiltight cover. The cup is filled with ordinary lubricating oil by removing the cover, first making sure that the plunger is pushed clear down. The stem of the cup has standard pipe threads which screw into the hub of the pulley.

Its operation is very simple. The rapid revolving of the pulley causes the loose piston to be forced outward by centrifugal action, thus requiring the oil to flow through the bi-pass A-B-C (see sectional drawing) to the shaft. The flow of the oil is controlled by the screw D and must be regulated according to the speed of the pulley. When the pulley stops oiling ceases at once.

Graphlio.—This new lubricant is being marketed by the firm of Walter D. Carpenter Company, 39 Cortlandt street, New York. It has been known for years that flake graphite possessed lubricating qualities of great value, but there was always the difficulty of getting it in fine enough form and at the same time free from all impurities, as to enable it to be used in combination with a liquid substance and remain in suspension. In Graphlio this firm claim to have surmounted all these difficulties, and such being the case, it should be of inestimable value to the automobile trade through its better and more efficient lubrication. It is sold in 10-oz. cans, which is sufficient to graphitize 15 gallons of oil.

"Triumph" Gasoline Gages.—These gages, for use in portable and stationary tanks, automobiles and motor boats, are the product of the Boston Auto Gage Company, Boston, Mass. In all types the pointer is magnetic and is controlled by a magnet carried on the float inside of the tank. The float is mounted in such a way that it must revolve as it rises or falls with the level of the liquid, and the magnet causes the pointer to revolve to correspond. There is no communication between the inside of the tank and the head of the gage, and if the gage glass should accidentally be broken it would be impossible for gasoline or air pressure to escape. Another form of the gage is arranged so that the dial may be mounted on the dash; this is known as the "tankoscope." The dial is made to represent the shape of the tank, and is arranged so as to show just where the gasoline level is inside, instead of using figures. It is practically the same as having a glass front in the tank.

TRIUMPH "TANKOSCOPE."

New Pittsfield Jewel Magneto Plug.—The Pittsfield Spark Coil Company, of Dalton, Mass., have brought out a spark plug which they have constructed especially for use with magnetos. This plug, called the Pittsfield Jewel double-spark

JEWEL DOUBLE SPARK PLUG.

plug, has been made with two gaps, as shown in the accompanying cut. This gives a double volume of spark, making more certain the complete explosion of the charge, even should the mixture become poor. The insulation of this new plug is the same as that used on the Pittsfield plugs manufactured heretofore by this firm.

VOL. XIX NEW YORK—THURSDAY, SEPTEMBER 24, 1908—CHICAGO No. 13

THE AUTOMOBILE

After Leaving Amagansett on the Road Across the Meadow to Montauk Point.

MANHATTAN'S "Automobile Row" had an enjoyable two days' outing on Long Island on Wednesday and Thursday, September 16 and 17, in which a considerable contingent of pleasure seekers, regularly entered as tourists, or volunteering for official duty, participated. The excuse for the happily conceived and well received junket for the tradesmen and their friends and all comers was by name a "two-day mechanical efficiency motor car test and run around Long Island." It was the conception of W. J. Morgan, who, in the interim of newspaper work, finds time to discover Ormond, to get cars to climb to the clouds, to persuade motor boats to cross the Gulf Stream to the Bahamas, and to suggest unending stunts to automobilists seeking for novelty and excitement.

The New York Automobile Trade Association saw a holiday ahead and readily consented to the event being run under its auspices. It duly appointed Morgan its manager and the "Senator" set Alex Schwalbach to work at the details and framing up a set of rules that would afford an acceptable and not too strenuous schedule and regulations that would not interfere too much with the holiday spirit of the affair. Schwalbach took an experienced tour manager and follower, R. H. Johnston, into consultation, and between the two they evolved an adequate set of rules. In brief, tardiness at controls lost a point per minute, and work on repairs, replacements, or adjustments a point per minute per man engaged, with no penalization for tire repairs.

Everything went off as merrily as a marriage bell. Every one was so "delighted" and had such a "bully good time" that Morgan's latest stunt was unanimously voted well worthy of annual repetition as a scheduled autumn trade outing. While the selling fortune of no make could be said to have been made, it is equally true that no serious damage was done any particular brand of automobile by the outcome of the run.

What more inviting two days' jaunt could be offered a New Yorker at his very doorstep than a two days' jaunt around Long Island? There was enough of cool autumn twang to the air to make the ride exhilerating. The first day's run was along the south shore, after a pretty ride through Bay Ridge, Bensonhurst, Bath Beach, over the boulevard along New York Bay. Then came the Merrick road, which further on becomes the South Pike, running through fashionable Babylon, Bay Shore and Islip, to the Hamptons and the picturesque Shinnecock Hills, with their quaint windmills and unique villas nestling on the sand dunes, and winds up at Amagansett. Break the run with a beefsteak dinner taken *al fresco* at Ye Anchorage Inn at Blue Point and one can ask for no prettier day's jaunt from the environs of the metropolis.

It would not have been Morganesque, however, to have furnished no spicier touring menu than such a peaches and cream jaunt over level macadams and smooth gravel highways as the run from Brooklyn Bridge to Amagansett. From this point as a *pièce de resistance* he had prepared a road tussle over a practically untraveled stretch of wild country to the eastern end of Long Island, where the Montauk Point light casts its ray over the conflux of sound and ocean. It was an almost pathless run for thirteen miles, at times through deep sand, at all times through some sand, and at some times with pretty stiff grades up the dunes and larger hills added. Troubles soon began and before the night was over in some cases they had developed into a series of real adventures.

It was well on toward sunset when the caravan entered the desert, with schedules varying from 50 minutes for the large to 59 minutes for the small cars in the run. The Amagansett turnpike had not been left many miles behind before cars began to be stalled and in turn to stall others following imprudently close behind them. It was a case of keep one another, for it was no easy task to pull out of the rut and around. It was soon realized that time was short and then hurry was the order of the day. Fair passengers got a merciless jolting and masculine live freight got a pretty bad shaking up. To add to the schedule making difficulty in such a waste there were few landmarks and cars went astray following the wrong trails. So it was that only about half of the cars got through on schedule and a majority of them made it with the narrowest of margins.

Two cars met with casualties in the battle through the sand that put them out of the run. H. M. Casbrunt's Lozier broke its differential in a rut and incidentally stripped its gears in endea-

Signs Which Marked the Route of the Run.

A Good Samaritan Whose Help Was Appreciated.

voring to extricate itself. A farmer was fortunately found to tow the car to Amagansett. A Stoddard-Dayton, piloted by R. L. Newton, was less fortunate. It broke a wheel and had to be abandoned until the arrival of a new wheel the next day. It had two ladies aboard. R. M. Owen insisted on starting back at 10 o'clock in the Reo to rescue the stranded party, but missed them in the dark. In the meantime they had started to walk to Montauk Inn. They followed the railroad tracks some of the way and reached the inn at midnight. Belated and lost cars straggled in all during the evening and night.

At a meeting of the committee to consider the cause of the delayed cars, it was leniently and diplomatically decided by Morgan and his advisers to call off the sand battle altogether and make Amagansett the end of the first day's control. There was no little kicking, as might be expected, from those cars that had survived the run through the sand, the only real test of the day.

The early arrivals preempted all the rooms at the inn not set apart for the ladies. The others to the number of close to 150 were forced to find their way as best they could to the steamer *Shinnecock*, which was moored at the dock, having been chartered to accommodate the overflow. The wind came up and became almost a gale. The boat rocked and banged against the dock, so that little rest was had in the four-dollar berths. Many were too sick to enjoy very much either their "dollar and a half" dinner or their "dollar breakfast." The favored inmates of the Inn, at $3 for a comfortable bed, a good dinner and a refreshing breakfast, were much envied.

The caravan got away from Columbus Circle at 7:20 A. M. on Wednesday, proceeded down Broadway, across Brooklyn Bridge, and along the Bay boulevard to the Crescent Athletic Club at Bay Ridge, where they checked out and were sent on their journey by Fred J. Wagner.

The cars were classified as follows: Class A, cars selling for $850 or less; class B, cars selling for $851 to $1,250; class C, cars selling for $1,251 to $2,000; class D, cars selling for $2,001 to $3,000; class E, cars selling for $3,001 to $4,000; class F, cars selling for $4,001 and over; class G, taxicabs carrying two passengers and driver.

The participants in the run were 28 contestants and 8 tourists, besides a half dozen official cars, making some 42 cars in all.

The first day's run was 144.4 miles from Brooklyn Bridge to Montauk. The checking stations were at Lynbrook, 34.5 miles; Blue Point, 73 miles; Southampton, 115.2 miles; Amagansett, 131.6 miles, and Montauk Inn, 144.4 miles. The schedule called for 19 miles an hour for cars over $2,000 and 17 miles for cars under that price all the way to Amagansett, and for 15 and 13 miles respectively for the 13-mile sand battle.

The start on the second day was made sharp at 7:30 A. M. It began with a run of 6.5 miles to Montauk lighthouse, which raised the distance of the run back to Amagansett to 25.8 miles. The Stevens-Duryea "Big Six" burned out its clutch in the run to the lighthouse and was delayed at the Inn until the next day.

Wednesday's route was retraced as far as Good Ground, 49.8 miles. It here turned north to Riverhead. There the Suffolk County Fair was visited and the track was circled three times. The next checking point was Stony Brook. The run then followed the north shore, whose hills gave the cars a bit of a hill-climbing tryout, with a checking station at Oyster Bay. The last checking station was at Flushing, 154.5 miles. From this point the cars ran as they pleased, via Astoria ferry, to the Automobile Club of America clubhouse, a distance of 9.4 miles, having run 315 miles in the two days.

The Official Results from the Committee.

At a meeting of the contest committee on Tuesday, the following cars were announced as having clean scores, both mechanically and on the time schedules, for the two days' run:

CONTESTING DIVISION.

Class.	No.	Make.
A	1	Cadillac.
A	3	Maxwell.
A	11	Reo.
A	22	Ford.
B	6	Reo.
C	14	Chalmers-Detroit.
C	35	Mitchell.
D	9	Mitchell.
D	10	Apperson.
D	15	Oldsmobile.
D	34	Stoddard-Dayton.
D	40	Pullman.
E	5	Mora.
E	12	White.
E	25	Stevens-Duryea.
E	29	Stevens-Duryea.
E	31	Locomotive Taxicab.
F	7	Rainier.
F	8	Rainier.
F	20	Zust.
F	21	Acme.
F	30	American Locomotive.

TOURING DIVISION.

Class.	No.	Make.
C	36	Maxwell.
D	2	Haynes.
D	16	Oldsmobile.
Spl.	13	Lancia.
Spl.	4	F-H Motorcycle.

In the contesting division, No. 4 Maxwell was disqualified for taking the wrong road from Montauk lighthouse back to Montauk on the second day. No. 18 Stevens-Duryea, entered by a private owner, was penalized 105 points for ignition troubles. Mitchell No. 26 was penalized 125 points, an oil feed pipe becoming clogged on the second day. No. 39 Lozier was disqualified and the driver disbarred from competing in future events under the auspices of the association for leaving the noon control at Blue Point without checking out.

The following cars dropped out at various times, but finally reported at the clubhouse after the time limit had expired:

No. 28 Lancia, No. 32 Brush, No. 24 Stevens-Duryea, No. 33 Stoddard-Dayton, No. 37 Autocar.

At an early date the certificates and medals will be presented at the clubhouse of the Automobile Club of America, to which function the automobile trade of New York will be invited. A musical program will be arranged, besides the luncheon for all.

One of the Most Enjoyable Features of the Run Was the Stop at the Typical Country Fair at Riverhead, L. I.

PREPARATIONS FOR A. M. C. M. A. SHOW PROGRESSING

IN order to complete final preparations for the first big show of the year, that of the American Motor Car Manufacturers' Association to be held at the Grand Central Palace in New York, December 31-January 7, 1909, there will be a meeting of the Committee of Management of the A. M. C. M. A., Tuesday,

Design for Main Entrance Grand Central Palace Show.

October 6, at 10 A. M., while the Show Committee will meet Tuesday and Thursday, October 6 and 8, at the same hour. All applications for space must be received at the New York headquarters, 29 West Forty-second street, by October 1, and those in hand by that date will be treated alike, while subsequent applications will be given consideration by the Show Committee, following the drawing and allotment of prior applications. To pass upon the latter, Chairman H. O. Smith, of the Show Committee, has set the following dates: Members of the A. M. C. M. A. will draw Thursday, October 8 at 10 A. M., while the allotment of space to automobile manufacturers who are not members of the association will be made the same day at 2:30 P. M., and that to makers of accessories who are not members of the Motor and Accessory Manufacturers' Association, will be made at 5 P. M.

The event will be known as the Ninth International Automobile Show, and it is quite probable that the S. R. Ball Company, long identified with the decoration of the Garden shows, will be awarded the contract for beautifying the Grand Central Palace. The latter is a very much more difficult structure to handle in this way, but it is said that the plans contemplate so complete a transformation of the interior, as well as part of the exterior, that those familiar with the Palace will hardly recognize it. Four designs have been submitted by leading decorators, but after several weeks' deliberation, the Show Committee has about settled upon the Ball plan, although it is the costliest. While full details are not available at the moment, it is said that the decorative scheme is borowed from an early English period. Pillars and balconies will be a feature, open beam construction being employed in connection with ornamental stucco. The main galleries will be white and sap green, relieved by gilt signs, while the ceiling of the main auditorium will be covered with an Italian sky-blue fabric, a garden with statuary, mirrors and a profusion of plants, occupying what is ordinarily the stage. A series of paintings will be run round the entire balconies, the subjects being taken from recent automobile contests.

Doubtless the greatest change in the building will be found in the outside, the porte cochére being decorated with ornamental cast figures, balustrades, electric signs and a large painting, the whole being brilliantly illuminated with search lights, in order to advertise the presence of the show. In place of the customary floor covering, a heavy fabric with liberal under padding will be employed, and there will also be a departure noticeable in the draperies of the accessory division, an entirely new arrangement of silkoline back draperies being outlined with a unique electrically illuminated sign, supplemented by satin banners.

Both the automobile and accessory exhibitors will be supplied with glass signs and pennants holding electric lights, the whole being mounted upon ornamental pillars. The specifications call for ten six by eight-foot statues throughout the building, and something like 10,000 electric lights for the decorative lighting.

PERFECTING PLANS FOR THE NINTH LICENSED SHOW

THE Show Committee of the A. L. A. M. met last Monday to consider plans for the Ninth National Show of the licensed manufacturers, which will open January 16 in Madison Square Garden. There were present Chairman George Pope, Marcus I. Brock, M. L. Downs and E. P. Chalfant.

Arthur N. Jervis was again appointed press agent of the show, and the contract for advertising was awarded to Lord & Thomas. The committee then took up the matter of decorative lighting, with the idea of introducing some novel effects.

Spaces were allotted to exhibitors in the commercial vehicle department, but it was necessary to postpone allotments in the electric division in order to arrange if possible for the room to accommodate the extraordinary demand. The headquarters of the committee during the show will be at the Hotel Breslin.

CONCERNING STIFF AND WEAK VALVE SPRINGS.

Stiff valve springs may close the valves with so much force as to break the heads from the stems, or they may break the stems at the key slots. Springs too weak to hold the valves or the cams will make the engine weak at high speeds, and will produce clattering owing to belated seating of the valves. If the springs are too stiff, and are shortened, the cut ends must be turned flat, which necessitates heating them in a fire and afterwards retempering.

PHILOSOPHY OF DRIVING A BOLT HOME.

When a bolt on which a nut is to be screwed sticks before it is fully introduced in its place, do not attempt to force it home by tightening on the nut. Drive on the bolt head with a hammer while the nut is being tightened, and strain on the bolt will be avoided. It is an excellent plan in many places to apply a paste of grease and graphite to the bolt threads before screwing on the nut. This makes the end easy to turn and gives protection against rust.

The Engineers and Their Hosts of the Diamond and Goodrich Companies at the Akron Country Club.

AUTOMOBILE ENGINEERS ENJOY OHIO HOSPITALITY

By CHARLES B. HAYWARD.

CLEVELAND, Sept. 19.—From early Friday morning until to-night, when the third quarterly meeting of the Society of Automobile Engineers formally broke up with the conclusion of the dinner tendered to the members by the Timken Roller Bearing Axle Company at the Courtland House in Canton, the visitors have been made to feel every moment of the time that they were in the hands of their friends, and the combined efforts of the entertainers left nothing to be desired. The result was one of the most enjoyable occasions that the members of the society have ever participated in. As the quarterly meetings only extend over two days, the first thing on the program was a number of factory visits during Thursday morning, in order to bring the business meeting and technical sessions in the afternoon. In a number of Winton, Stearns, Peerless and White cars, the party got away from the Hollenden about 9:30, the first plant on the list being the Winton, where the engineers were welcomed by Mr. Henderson. After having spent an hour or so there in examining the various factory methods employed, as well as the details of the design of the new Winton cars for 1909, a number of which were coming through, the cars were again taken for a visit to the plant of the Standard Welding Company, situated in another part of Cleveland.

The invitation to inspect the plant was extended by W. S. Gorton, general manager of the Standard Company, and after having viewed some of the various forms of electric welding as applied to rims, axles and tubular work, the regret that more time could not be devoted to the visit was universal, but in view of the fact that no less than six different plants, situated in widely separated parts of the city, had to be visited in a very limited time, it was impossible to devote more than passing attention to any one of them. From the Standard company's plant the cars were again taken for a visit to the Peerless factory, and at this, as well as at a number of the other plants visited, the fact that the slump of a year ago has been completely forgotten is more than evident in the number of large and permanent additions to the different factories that are now in course of construction, while the manner in which the 1909 cars are already coming through shows that the demand for new machines is making itself felt in no uncertain manner, early in the season. After having spent an hour or so at the Peerless plant, the cars were once more taken, and when the photographer had finished repeating his efforts of earlier in the morning, they were headed for the plant of the Hydraulic Pressed Steel Company, at the invitation of J. G. Foster, one of the members. It was intended to have had some of the special operations of automobile frame pressing on the huge hydraulic presses for which this plant is noted, under way during the visit, but owing to Cleveland's unusually early dinner hour, 11:30, this was impossible.

As a matter of fact, so much more time was spent in visiting than had been allowed for, that at the hour set for the lunch there were still two plants at widely separated points to be gone through, so that at the suggestion of J. G. Sterling, of the Stearns company, and chairman of the local committee, it was decided to omit the visit to the plant of the F. B. Stearns Company, owing to the great distance from the Hollenden. This gave more time to see the workings of the new White plant, though what was left constituted but a fraction of the time that could have been profitably spent there, as it was the universal consensus of opinion that nothing finer in the shape of systematic arrangement and factory organization had been seen. The members were met at the plant of the White company by Windsor and Rollin White, who, together with some of the technical members of the company's staff, acted as guides during the tour of the wide-spreading plant, all of which, with the exception of the large administration building, now nearing completion, is of one story and of the saw-tooth type of construction. The distinguishing feature of the lay-out of the plant, consisting of a 25 by 600-foot skylighted alley, by means of which any one of the numerous departments may be reached without going through any other, came in for a great deal of favorable comment, as did also numerous other features of the carefully arranged factory, which gave evidence of the pains spent in planning it so as to insure not alone the maximum capacity for turning out work, but likewise the greatest comfort and con-

Preparing to Depart from The Standard Welding Plant.

venience for the workmen. An opportunity was also presented to examine the details of the power plant of the White car for 1909, which has been greatly simplified by the adoption of the Joy type of valve gear, this permitting the shortening of the crankshaft to an extent where but two annular ball-bearings are now employed, in place of eight.

Following the visit to the White plant, the engineers were taken back to the Hollenden, where a lunch was served in the dining room of the Automobile Club of Cleveland, at the invitation of E. E. Allyne, of the Allyne Brass Foundry Company, Cleveland, and a member of the Society. Upon the conclusion of this, the members adjourned to the assembly room of the Hollenden for the business meeting and technical sessions.

The meeting being a quarterly one, there was but little routine business to come in for attention, the chief items being the rehabilitation of the committee on international memberships, owing to the resignation of the chairman, and the appointment of nominating and local committees—one to prepare a ticket for the annual election to be held in connection with the fourth annual meeting, which will take place in New York City during the shows, and the other to take up the matter of arrangements and entertaining on the same occasion. In order to provide an opportunity for the greatest possible number of members to attend the fourth annual meeting, both the business meeting and the technical sessions will be spread over two days on dates sufficiently far apart to enable those visiting but one or the other of the shows to be on hand.

Technical Sessions Were Interesting.

The business meeting was followed by the technical sessions, and although the number of papers presented, as well as the time available for discussion, was short, they proved of considerable interest and will doubtless lead to further contributions along similar lines. The first paper was on "The Limitations of the Universal Joint," by H. Vanderbeek, and consisted of a study of the characteristics of this familiar mechanism, as well as its use on the automobile, raising the question of the desirability of one or two universals on the propeller shaft of a car, from a theoretical as well as a practical point of view. In connection with his paper Mr. Vanderbeek had constructed an ingenious model to prove his theories, and this was shown and explained at the conclusion of the discussion, which brought out a number of interesting points.

Following this, there was presented by President Fay a paper on "What Carbon Does to Automobile Steel," in which the author showed at some length the desirability of low carbon steel for automobile work, particularly where dynamic stresses have to be borne, pointing out at the same time the relation of low-carbon, unalloyed steels to both high and low-carbon alloyed steels, where their value for automobile construction was concerned. The subject is one upon which a great deal has been written, though not from this particular point of view, and a discussion of the various points involved could be carried on almost indefinitely.

A paper on the subject of "Power Transmisison on the Automobile" was to have been prepared and read by L. M. Dieterich, but, owing to his illness, he was unable to finish the paper in time for the publication of the Transactions of the Society, or to attend the Cleveland meeting. The third paper presented was entitled "What Is the Best Timing?" and consisted of a translation from the French of *Omnia* (Paris), by Charles B. Hayward. The French author, Louis Lacoin, as the result of the appearance of a device known as the *Larrad*, made a critical study of the requirements of motor valve and ignition timing, comparing them both with the formula prescribed by Larrad, the inventor of the device, as well as with the standards adopted by no less than thirty well-known French builders, who have turned out thousands of motors in the past few years. The principal purpose of the translator was to bring up discussion and lead to further contributions on a subject that has been neglected to a very great extent by the members of the Society in the past, but as the paper itself showed, there are so many points involved, not a few of which require study for their proper consideration, that it is impossible to discuss the subject satisfactorily at any length except in the shape of written contributions, a number of which were promised. Following the conclusion of the technical sessions, the meeting was adjourned to reconvene at a dinner given by the Society to the visiting members, in the rooms of the Automobile Club of Cleveland, in the Hollenden.

A Park Stretch En Route to the Winton Factory.

Program of the Second Day.

At the invitation of the B. F. Goodrich Company and the Diamond Rubber Company the society made a visit to Akron, thirty miles distant, in order to inspect what are said to be the largest rubber works in the world. The concerns in question provided a special car on the electric interurban system, and this appeared in front of the Hollenden promptly at 7:40 a.m., according to schedule. The members were all on hand, and after a pleasant run of a little less than two hours, were landed right at the door of the B. F. Goodrich Company's plant, where a number of the technical staff of the works were impressed as guides in order to give the visitors as comprehensive an outline of the multitudinous operations carried on in a rubber manufacturing plant of such extensive proportions, as was possible in the limited time at their disposal, as both the Goodrich and the Diamond plants had to be visited between 9:30 and 12:30, the hour set for the lunch at the Akron Country Club. Urgent invitations from both the Goodyear and the Firestone companies to inspect the workings of their plants had to be declined for the same reason, as well as the fact that the former had not been received until it was too late to make any change in the plans for the trip to Akron.

The representatives of the local committee, consisting of Chairman Sterling and H. W. Alden, accompanied by Secretary Hayward, made a visit to the plant of the Firestone Tire & Rubber Company, where they were presented with an attractive souvenir in the shape of a neat stop-watch for each of the visiting members. To commemorate the date of the meeting and

visit, the watches are engraved "Firestone, September 19, '08," on the back of the case.

Even by going through "on the high" for every step of the way, it was wellnigh impossible to give the visitors more than a sketch outline of the great variety of rubber "industries" housed in the plant of the Goodrich company. They really deserve this title, as, apart from the fact that the production of an article having rubber as its foundation is the basis of all of them, they not only differ greatly, but require for their housing buildings that are respectable-sized factories in themselves. Needless to add, this is particularly true of the tire end of the plant, where the thousands of solid and pneumatic tires turned out every day have an enormous value. Few, if any, of the members had ever had an opportunity of visiting a tire-making plant, so that the numerous operations, and particularly the preparation of the crude material, was found to be extremely interesting. Starting with the making of solid tires, the visitors were given at least a brief view of every one of the twenty-odd departments, which, in the aggregate, employ between three and four thousand operatives the year round, before bidding farewell to the Goodrich establishment and walking across the intervening space that separates it from the Diamond Rubber Company's works.

It might be thought that seeing one rubber factory was equivalent to seeing all, but where both solid and pneumatic tires are concerned particularly, each plant has methods and arrangements of its own that become of more than the usual interest when contrasted with the different methods of accomplishing the same ends to be seen in the other plants. On this account, it was generally regretted that a whole day could not have been spent in Akron. However, the factories not only close for the day on Saturdays at 11:30, but it was planned to spend the afternoon in Canton, at the invitation of the Timken Roller Bearing Company, a dinner at the Courtland following the inspection of the plant.

At the plant of the Diamond company a good idea was obtained of the various processes through which Diamond tires go before emerging as the finished article, ready to be applied to a car, and the members were greatly interested in the large amount of special machinery used in the manu-

Mr. Henderson of the Winton Company Acts as Host.

The Camera Man Got Busy at the Peerless Plant, Too.

Leaving the White Factory for the Hollenden Headquarters.

The Timken Company Entertained the Engineers During Their Stay in Canton.

facture of other articles of rubber, and particularly that employed for insulating electric cables. Tire-making, as a matter of fact, is almost entirely a matter of hand work, which, together with the high grade of the rubber necessarily employed, accounts for the great expense of manufacture.

Immediately upon the conclusion of the visit to the Diamond plant, a number of cars were boarded for the run to the Akron Country Club, where the members were the guests of the two companies at luncheon. Following this, the special electric car was again boarded for the run to Canton.

At the terminus of the line the visitors were met by a special delegation from the Timken plant, and a number of automobiles, and as a prelude to the visit to the former were given a view of the famous McKinley monument, for which Canton is noted. The various operations involved in the manufacture of the well-known Timken roller-bearings were then inspected, as well as the die-forging of single-piece front axles, manufacture of gears and other processes necessary to the turning out of complete front and rear axle units, the new one-piece pressed-steel trussless rear axle driving unit that is being made for the 1909 model cars coming in for a great deal of favorable attention.

After having made a pretty thorough inspection of the workings of the various departments of the Timken plant, the visiting members were guests of the company at a dinner given at the Courtland house, Canton, upon the conclusion of which the meeting came to an end. A vote of thanks was passed and the secretary was instructed to forward a copy of the resolution to each of the many companies that had done so much to entertain and instruct the visiting members. These included the Winton Motor Carriage Company, F. B. Stearns Company, Peerless Motor Car Company, Standard Welding Company, Hydraulic Pressed Steel Company and the White Company, in Cleveland; the B. F. Goodrich Company, Diamond Rubber Company, Firestone Tire & Rubber Company and Goodyear Tire & Rubber Company, in Akron, and the Timken Roller Bearing Company, in Canton.

ENGLISH DAIMLER ADOPTS KNIGHT VALVELESS MOTOR

CHICAGO, Sept. 21.—Announcement was made to-day by Knight & Kilbourne, of Chicago, manufacturers of the Silent Knight valveless motor, that a deal had been consummated in England by Charles Y. Knight, designer of the engine, whereby the Daimler Motor Co. will equip all its cars in 1909 with the Silent Knight motor. Also it is announced that the same engine will be used by the Minerva people in Belgium, that deal having been closed some time ago. Other foreign concerns are investigating the merits of the idea and it is said it is not at all improbable that the Chicago-made engine will be adopted by some of the leading makers on the continent. At the present time the Panhard people are conducting a series of tests at their factory, and it is said that so interested are the Fiat makers that they have sent their designers to Paris to watch the experiments at the Panhard factory. The makers of the Mercedes, too, have asked to be shown the merits of the idea.

The Silent Knight motor first was brought out in Chicago by Knight & Kilbourne, who put it in the Silent Knight car built by them for a couple of seasons. Early in 1907 Mr. Knight succeeded in interesting the Daimler people in his engine, and last November he went to England to demonstrate it at the Daimler works. He has been there since, in which time the Daimler engineers have gone over the engine, and, while retaining the cardinal principles, they have thoroughly remodeled the motor. As is well known to those who examined the Chicago motor at the shows, the principle embodied in the engine is the elimination of the ordinary tappet valves and the substitution of sliding parts by means of two sliding sleeves working between the waterjacket and the cylinder proper and operated by an eccentric motion, opening ports in the cylinder walls as the surfaces pass over each other. The head of the motor is detachable and efficiently water-cooled, and the spark plug is placed exactly in the center of each head. Each cylinder of the motor has an explosion every two revolutions instead of one at every revolution; otherwise it is credited with having all the good points of the two-stroke engine without any of its drawbacks.

With the Silent Knight engine gas is drawn in on the induction stroke, the inlet port being closed by the sliding sleeve and it is asserted the inlet and exit of the gases through the ports are easier and more direct than through the ordinary valve opening.

The remodeling of the Silent Knight motor by the English engineers, aided by Mr. Knight in person, brought about the elimination of a third port, which had been used as an auxiliary exhaust outlet at the bottom of the stroke, but which had been deemed unnecessary by Designer Knight long before he went to England. This was the principal change made by the English, who now claim that the engine is really silent in action, for, with the exception of the exhaust, there is nothing to make noise, the movements being of a gradual and sliding order, and there being no tapping movements or spring return operations.

HORSE-POWER RATINGS OF AUTOMOBILE MOTORS

By THOS. J. FAY, President Society of Automobile Engineers.

TO derive the horsepower ability of a motor in the absence of an actual test, is but to make an attempt to anticipate what the actual test would naturally disclose. It follows, therefore, that the actual test is the one best way: all others are simply approximations, and nothing more. Some engineers employ very simple and abbreviated empirical formulæ, in order that the attempt at the approximation will be the least possible trouble. In one case that came to the notice of the author, the error was 50 per cent the wrong way, i. e., the motor was capable of delivering 50 per cent more power than the makers thought it would.

The necessity of parading an overgrown horse power rating is not apparent, since if the motor is big enough to do the work, the smaller it happens to be, in any given case, the better for the owner of the car it is used to run.

The most abbreviated formula yet offered, is that used by the *A. L. A. M.*, as follows:

$$H.P. = \frac{d^2 N}{2.5}$$

in which

$H.P.$ = the alleged horsepower of the motor;
d^2 = the square of the bore of the cylinder in inches;
N = the number of the cylinders;
2.5 = a constant said to serve the purpose, in view of the actual ability of motors, and in further view of the similarity of the several makes of motors.

This formula says that a motor, of any stroke now used in automobile motors, will cover the requirements on the ground that the several motors are so near in point of stroke, as not to make a material difference in the actual power delivered by them.

Taking a given sized motor, as a four-cylinder, 4 x 4 in., bore and stroke of cylinders and pistons respectively, the rating would be:

$$H.P. = \frac{4^2 \times 4}{2.5} = 25.6$$

It is assumed that the speed will be the maximum possible; the highest attainable under which the product of the torque and the speed will afford the maximum possible. To obtain any kind of accuracy, quite a number of assumptions would be necessary, to say the least. But if all the motors are very much alike, and all are compared by the one formula, results a little high, or a little low, as the case may be, a correction can be introduced at any time, and will serve equally for all. No sooner is a rule promulgated than there is a desire to get around it. This rule, for instance, is the root of the innovation known as the "short stroke" motor. When the rule was promulgated, the majority of motors had strokes not far from 5½ inches, with a few longer, and some with a shorter stroke.

Importance of the Stroke as a Factor.

That the stroke does enter into the problem, can scarcely be denied, and that the stroke is now shorter than it would have been, in the absence of the rule, is a matter that can be taken for granted. Yet, it is possible the short stroke is a very good thing, from more than one point of view. The motor is lighter, the cylinder castings more regular and the difference in power is not so great as to defeat the main objects. As before stated, if a motor is of the proper size to do its work, it is the right size to use, on the ground of economy. If a motor is so large that it cannot be run at its economical load, its higher full load efficiency is valueless, since in service the necessary full load will not be available. A smaller and probably less efficient motor might serve with better results, for the very simple reason that it may be run at its most economical load.

An empirical formula, taking the stroke into account, might read as follows:

$$H.P. = \frac{d^2 (l\,k)\, N\, S}{10^5} \times f = \text{approximate horsepower,}$$

in which:

d^2 = the square of the bore in millimeters;
l = the length of the stroke in millimeters;
k = a constant, depending upon the length of the stroke;
N = the number of the cylinders (four-cycle motor);
S = angular velocity in revolutions per minute;
f = a factor of compression;
10^5 = a figure of convenience;

If the bore is not over six inches (152.4 mm), the values of k might be taken thus:

k = unity for six-inch stroke;
k = .90 for a five-inch stroke;
k = .80 for a four-inch stroke;
k = .70 for a three-inch stroke;

The exact values of k would certainly be subject to several conditions and to a series of variables besides. In a matter of this sort, however, many of the conditions tending to shift the k values would cancel themselves in service. These values are also dependent upon one other consideration that cannot well be eliminated, i. e., the speed of a four-inch stroke motor will be higher (considering the highest value of speed and torque) than the speed of the six-inch motor, and it follows that the actual reduction of power due to shortening the stroke is in a measure compensated for by the increase in speed, but the compensating factor will not suffice to wholly counteract the influence of the shorter stroke.

This counter influence, however, does so materially aid the process, as to warrant one in taking the k values as given, rather with the hope that, in the better class of motors, the k values might be increased somewhat. It must not be assumed, though, that the mere fact that a short stroke motor would run at a very high speed, is a warrant for so doing; there is a limit in practice to the speed *per se;* and that is the limit to take into account in deriving any empirical formula, on the ground that such a formula is but a practical device, at best. It would be out of the question to attach a theoretical speed to a practical formula and call the whole practical.

Effect of Stroke on Compression.

The values of f will change with the compression, and with the fuel, considering a given compression. If gasoline is taken as the fuel, and the compression ranges between 75 and 95 pounds per square inch absolute, the f values for the conventional types of four-cycle automobile motors might range about as follows:*

f = 5 at 75 pounds per square inch (absolute) compression;
f = 5.5 at 85 pounds per square inch (absolute) compression;
f = 6 at 90 pounds per square inch (absolute) compression.

In these deductions will be found ample room for controversy, for reasons that, in a theoretical sense at any rate, are perfectly good. On the other hand, it is a fact that motors, as they actually obtain, will not do better than the values of f as here given. But the author attaches more importance to the effect on the speed of the motor, as a result of higher compression, than he does to the direct influence of that compression. In other words, if the compression is low, a relatively slow speed motor will result due to ignition troubles, more than to anything else, at the higher speeds. But if the compression is high, approaching the point of pre-ignition, the ills that such a condition will engender must be borne. Increasing speed, unfortunately, increases the richness of the fuel and increases the hydrogen present. If it is true that different mixtures of a given fuel will perform differently, it is well within the bounds of good practice to say, equal mixtures of different gases will not afford equal results. It is plain then that a high compression can result in increased power, and would influence the f values, more than the

* The values of f given are on a basis of the actual compression, at the speed of the motor, at which the power is delivered. Cold compression is quite another matter.

amount given, were it not for the fact that the conditions to be maintained are beyond the bounds of common practice.

In a racing car, for illustration, it is possible to utilize the higher compression because the driver is skilled and the carburetion is looked after in the most careful manner. The more complete formula, taking the same problem as before, would afford results as follows:

$$H.P. = \frac{100^2 \times (100 \times .80) \times 1500 \times 4 \times 5}{10^9} = 24$$

which is a very high value. Built as some motors are, the factor of compression might well be 4 instead of 5. Certainly, the average motor of this size uses enough fuel to enable it to deliver the power stated, and if the thermal values, usually taken for motors, have any underlying reason for their existence, it is within the range of probability that the values given are approximately right. It is the factor of compression that must be adjusted, as between the respective motors and the author cannot accomplish such a task, merely in the act of devising a formula. This statement strikingly illustrates the earlier one, i. e., "the actual test would naturally disclose the actual horse power of a motor."

Conditions Affecting the Torque.

The horsepower of a motor increases in direct proportion to the speed, if the torque holds constant. It is unfortunate that the torque does not remain constant, nor does it increase with the speed. Indeed, it falls off with alarming rapidity under certain conditions as:

(*a*) If the compression is low and the mixture leaks by the valves or the piston.
(*b*) If the valves are too small.
(*c*) If the valves are not properly timed.
(*d*) If the cooling system is defective, a common complaint.
(*e*) If the spark is not properly timed, assuming it is otherwise adequate.

If it is true the torque will not hold constant, with increasing speed, this fact must be taken into account in any formula, but since it is the lowering compression that effects the torque, it is the factor of compression that must be adjusted in an empirical formula.

The torque of a motor, which for convenience may be called the "mean effective pull in pounds," at unit radius (one foot), may be known as follows:

$$H.P. = \frac{2\pi\left(\frac{H.P. \times 33{,}000}{2\pi SP}\right)\left(\frac{H.P. \times 33{,}000}{2\pi RP}\right)\left(\frac{H.P. \times 33{,}000}{2\pi RP}\right)}{33{,}000}$$

hence:

$$P = \frac{H.P. \times 33{,}000}{2\pi\left(\frac{H.P. \times 33{,}000}{2\pi SP}\right)\left(\frac{H.P. \times 33{,}000}{2\pi RP}\right)}$$

Simplifying the formulæ will result in the following:

$$P = \frac{H.P. \times 33{,}000}{2\pi RS} = \text{pull in pounds, at radius taken;}$$

$$R = \frac{H.P. \times 33{,}000}{2\pi PS} = \text{radius;}$$

$$H.P. = \frac{2\pi RSP}{33{,}000} = \text{approximate horsepower;}$$

$$S = \frac{H.P. \times 33{,}000}{2\pi RP} = \text{angular velocity in revolutions per minute.}$$

The Working Requirements Are Numerous.

There would be no need to set down the above formulæ, either in the involved or in the simplified form, except to show the source of the simplified form and to point out that in mathematics the abstract is ever available, to no practical purpose, since to know the value of the horse power or the torque, one must first determine their values by an actual test. Having made tests on the various types of motors, however, one may then assume values to the extent necessary to obtain the remaining values. If we assume the radius as unity, it does not become necessary to solve for the same; likewise, if we know the maximum speed permissible in practice, this may be assumed, if it is known that the motor will perform at such a speed.

For a motor to merely turn over at a given speed is not enough; it must deliver power in a manner to satisfy the formula, else the speed assumed will introduce a fallacy. The only way to be certain that the speed will be that of the maximum power, is to test the type of motor under actual service conditions sufficiently to establish the facts. The relation of speed to torque, in actual practice, is such that the maximum power does not, as a rule, obtain coincident with the maximum speed or with maximum torque. As the formulæ show, the power is in direct proportion to speed and to torque; as the speed increases, the power increases, if the torque remains constant, which is not true in practice, as the following records of tests will adequately illustrate:

SPEED AND TORQUE TEST.

150 mm stroke and bore Fiat motor, four-cylinder, four-cycle.

Speed in r.p.m.	Pull in lbs. at 1 ft. rad.	Speed × Torque.
1,090	341	= 1,090 × 341 = 371,690
1,412	315	= 1,412 × 315 = 444,780
1,800	262	= 1,800 × 262 = 471,600
1,920	210	= 1,920 × 210 = 403,202

As will be observed, the maximum value, due to multiplying speed and torque, fell at the point next to the lowest established by the test, and with the speed next to the highest observed during the test. A number of trial tests were made, to show that no better results would follow at other higher or lower speeds. Increasing the speed beyond the highest speed given above resulted in an alarming reduction of the torque, while at lower speeds than the lowest recorded here, there did not result such an increase as to compensate in any measure for the reduction in speed. The general behavior of the motor was such as to lead one to the conclusion that no further display of skill would enhance the results in any way.

Where the Empirical Formula Fails.

No empirical formula would predict any such results, because in this case the maximum power was produced at a piston travel of 1,800 feet per minute, which is 800 feet per minute higher than the empirical formula contemplates. The formula of the A. L. A. M. would fix the horsepower-rating of this motor as 57.6. To show how much motors can vary, another torque test was as follows:

SPEED AND TORQUE TEST.

165 mm bore × 170 mm stroke, four-cylinder, four-cycle motor.

Speed in r.p.m.	Pull in lbs. at 1 ft. rad.	Speed × Torque.
800	446	= 356,800
900	390	= 351,000
1,000	350	= 350,000

Below 800 r.p.m. there was no increase in torque to compensate for a reduction in speed, hence it was fair to take 800 r.p.m. as the speed of maximum power. This was a case in which the maximum power was developed, below the piston travel (1000 ft. per minute) assumed in the case of the A. L. A. M. formula. Both of these motors were designed to do just what the tests showed; one as a motor for racing cars, in which the power of the higher speed could be utilized for a short time, and the other for a racing motor-boat, in which the propeller could not (at that time) be designed for a higher speed. Both were used in automobile work, but only one could claim a place in boat work, that is, on a basis of the delivery of the maximum power. In marine service, the last-named motor would deliver the maximum available power at a lower speed, because it was designed to do so. How, then, can any simple formula serve for all motors, in view of such marked differences? Indeed, the differences noted do not cover the range, because both motors cited were of the finest of the time, and indifferently designed motors would not do nearly as well as either one of them.

(To be Continued)

GETTING ACQUAINTED WITH A CARBURETER

By HERBERT L. TOWLE.

MANY pages have been printed on the subject of scientific carbureter adjustment. Nevertheless, the man who has installed a carbureter of unfamiliar make is apt to find all his carefully studied principles oozing away as he heatedly grinds away and the motor fails to start. It was easy enough to preserve a scientific frame of mind so long as he had some other fellow's trouble to deal with, but it is quite another matter when repeated breathless spinnings of the crank have brought no result, and in sheer demoralization one is tempted to suspect spark plugs known to be clean, batteries known to be fresh, and spark coils which were in perfect working order up to the instant the old carbureter was taken off the car.

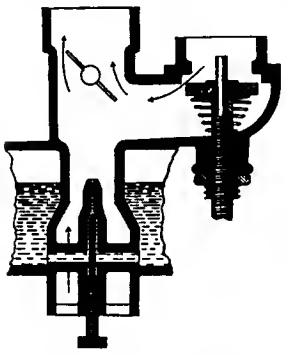

Fig. 1. — Typical Automatic Carbureter. Primary air opening is fixed. A needle valve controls the spray orifice. Spring tension and lift of auxiliary air valve are separately adjustable.

The human mind is incapable of retaining more than a limited number of ideas at once, and the stress of one dominant sensation or experience may for the moment drive out of mind other ideas which in calmer moments would be accorded their due weight. It follows that when you are telling your neighbor how to adjust his carbureter you can split hairs all you like, but when you are adjusting your own your formulas cannot be too simple. Even after the engine has been started your troubles are by no means over. You adjust the carbureter so the engine runs well on the floor, and find that when you take the road the car will not get out of its own way. You adjust to give respectable speed, and find that you cannot start. Then you begin all over again, and possibly find that when the car runs fast on the level it pulls badly on hills, or that when it takes grades nicely the motor overheats at high speed, and drinks more gasoline per mile than you had believed was possible. Or perhaps you are totally unable to get an explosion. Worn out with your exertions, you shut the tank valve and sit down to smoke a cigar. Then you try again, following apparently the same routine, and the motor starts off as if nothing was the matter.

The nonautomatic type may be ignored, and the automatic carbureter may be broadly classified into the auxiliary air valve and the "puddle" types. Owing to certain characteristic differences in behavior it will be best to treat these types separately. Inability to start the engine, to speed up, or to run as slowly as one would like may all be due to either too little or too much gasoline. To determine which is the cause one must be guided by other and sometimes very subtle symptoms. Of the grosser symptoms of poor mixture it may be said that overheating, if not due to slipping of the fan belt or clogging of the water passages, is caused generally by too much, rarely by too little, gasoline. Black smoke indicates a very considerable excess and popping in the carbureter indicates too little.

As the first essential is to get the engine started, we will consider that first. With any spray carbureter, the mixture for starting must be obtained by priming. It is, however, possible in this manner to make too lean or too rich a mixture; and if the adjustments are decidedly wrong the mixture formed on the first few revolutions will be so bad that the motor will stop. Sometimes the float is too high or too low, and the gasoline overflows continually, or is so low that great suction is required.

It is best to observe whether gasoline drips after the float chamber has had time to fill. If no dripping occurs, depress the float, and on the first sign of dripping crank the engine immediately. If it does not start, prime the carbureter again. If this fails, shut off the gasoline at the tank, and if there is a drainage outlet from the float chamber draw off a couple of teaspoonsful of gasoline. This weakens the mixture. Repeated cautious experimenting in this manner will soon establish the priming required to start the engine when cold. When it is warm the gasoline evaporates more rapidly, and caution is required not to prime too much. Many carbureters with a small primary air passage will start the engine without priming.

If the engine starts, but immediately dies down, try holding the float down. If the cause of dying down is too weak a mixture, this will keep the engine going. See that the gasoline level is not more than 1-10 inch below the spray nozzle. If the engine still stops, the mixture is too rich.

If the carbureter drips when standing, the float valve should be investigated. If pressing it shut stops the dripping, the float is too high. If the dripping persists, the valve leaks and must be ground to a fit, preferably using pumice stone, since emery is liable to embed itself in the brass. Occasionally a float and float valve are so arranged that the valve, although tight in one position, may slant over a trifle and leak from that cause. Such carbureters are a nuisance, since the gasoline level constantly varies. The automatic air valve is not supposed to open when the engine is run slowly with the clutch released; consequently we have first to deal only with the adjustment of the spray orifice or of the primary air opening. Some carbureters have a fixed primary air opening, and control the spray orifice by a needle valve, while others have a fixed spray orifice and control the primary air intake. Reducing the primary intake produces a greater suction, and is equivalent to opening the spray orifice. Adjusting to keep the engine running on a low throttle is therefore a simple matter. Let us assume the engine to run smoothly on a low throttle. The spark is now fully retarded, and with the clutch still disengaged the throttle is slightly opened. The engine should accelerate smartly, and should attain at least its maximum road speed on about one-eighth of the full throttle opening. The auxiliary air valve should open, but not to its full extent, as the engine is not taking full charges. If it opens fully, the spring is too weak, and its tension should be increased.

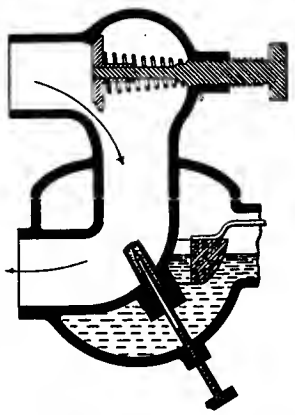

Fig. 2.—A simple form of Carbureter. All the air enters at one point and passes around the spray nozzle, but the inlet opening is enlarged by the automatic air valve as the suction increases, thus preventing the suction from becoming excessive. The spring tension, but not the lift, of the auxiliary air valve is adjustable.

The second step is to try the car at moderate speeds on the road, and here the real process of adjusting begins. Let us suppose—what is likely to be the case—that the engine is sluggish. Without stopping the engine, try slight changes in the spray orifice or primary air inlet. First reduce, then increase the richness, and note the effect on the car's performance on level ground. An adjustment will presently be found with which the car runs well at ordinary speed. Now turn your attention to the auxiliary air valve, and bear in mind that you do not yet know that the mixture at ordinary speeds is correct; you may be driving with the throttle wider open than it should be. Note whether the radiator seems to heat up on the

level ground, also if there is a tendency to weakness and overheating on hills. These symptoms indicate tbat the mixture is too rich. Notice whether the auxiliary air valve opens sufficiently (*i.e.*, from one-eighth to one-fourth inch, depending on the size). Adjust the stop to increase the lift slightly, and slacken the spring. Remember, however, that a change in the spring tension has a greater proportional effect at low than at high speeds. This is very important. If easing the spring helps matters at medium but not at high speeds, note whether the auxiliary valve strikes the stop before the engine reaches its maximum. If so, the high speed mixture is too rich. If the construction is such that the valve can open further, adjust the stop accordingly. If, however, it flutters and behaves irregularly, the lift must be restricted. Increase the spring tension again and reduce the spray orifice. If thcre is no needle valve controlling the spray, reduce the primary opening so that a larger proportion of the total air stream will go through the auxiliary valve. These changes will weaken the mixture more at high than at low speeds, which is desired.

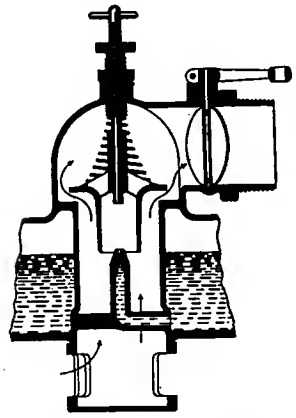

Fig. 3.—In this type of carbureter all the air enters by one inlet, but part of it is shunted around the spray and does not take up gasoline. The nozzle has no needle valve, but the size of the air inlet is adjusted by a fixed shutter.

Suppose, on the other hand, that instead of overheating the motor was simply weak. It is a good guess that the mixture is too lean. Possibly the auxiliary valve spring is so weak that the valve opens fully at low speeds; or perhaps the lift is too great for the size of the engine. It is not usually difficult to modify the low-speed adjustment so that the car gives its maximum power and speed, and this should be the third step. There is less room for uncertainty here than about the low-speed adjustment, since unless the mixture is actually about right the maximum speed of the car will not be reached A good test of the mixture is the response to the spark advance. If the mixture is bad the spark must be advanced considerably to produce any noticeable acceleration, whereas with the correct mixture any change in the advance is at once felt, and the maximum advance is not needed except at maximum speeds. Even more marked is the response to the throttle when the latter is nearly closed, and this is therefore the best low-speed test.

When the high speed adjustment has been found, the fourth step is to see whether the car will do equally well at ordinary speeds. If it does not, one can generally tell whether the mixture is too rich or too lean by recalling what was done to make it correct at high speeds. For example, suppose the improvement at high speeds to have been obtained by increasing the auxiliary spring tension. This enriched the mixture at high speed, but enriched it more than proportionately at lower speeds as well. It is possible that the auxiliary spring is wound from too light wire or has too many turns, so that it is under too much initial tension, and therefore does not yield to the suction as soon as it should. Before changing the spring, however, try slackening it to its earlier adjustment, allowing the valve to open under moderate suction, and open the spray orifice slightly or reduce the primary air inlet. This will still give the desired mixture at high speeds, but will give a leaner mixture at low speeds. Suppose thc mixture was found to be originally too rich at high speeds, and was corrected by slackening the spring or increasing the auxiliary valve lift. If the change was only in the lift the mixture at lower speeds has probably not been affected. If, however, the spring has been slackened, the mixture may be too lean at low speeds, owing to the air valve opening too soon. One way to correct it would be to use a spring having a larger number of coils, but a satisfactory result may usually be reached by increasing the spring tension and reducing the spray orifice.

Where the carbureter is of the puddle type the physical manifestations of rich or lean mixture will be quite the same. It has certain individual peculiarities, acquaintance with which will smooth the owner's way considerably. This type of carbureter differs from tbe spray type in having a U-shaped mixing chamber, in the base of which a puddle of gasoline about 3-32 inch deep is maintained by an annular float. As this puddle is supplied by gravity, a weaker suction will produce a mixture than where the gasoline must be both lifted and atomized by suction. As the puddle is constantly supplied, it will evaporate continuously as long as the tank valve is open, and when the motor is not running it may produce a mixture too rich to ignite, particularly if the engine be hot. If the float valve be so high that flooding occurs, this effect will result very quickly. If, therefore, a carbureter of this type does not start the engine immediately on priming, the chances are that the mixture is too rich. The tank valve should be shut and a little gasoline drained from the float chamber, when the motor will start easily.

This type of carbureter is very sensitive to changes, both in the float level and in the needle valve adjustment. A single turn of the screw adjustment of the float valve is equivalent to wiping out the puddle or doubling its depth. The easiest way to ascertain the correct adjustment is to connect up the carbureter with thc intake in such a position that one can see the puddle, either directly or by a small mirror and electric flashlight. When approximately the right level has been obtained, further adjustment will be a matter of marking the float valve stem and turning its threaded adjustment not more than one-eighth turn at a time until the correct position has been found. If the float is too high the engine will be hard to start, and will accelerate badly, overheat and show poor power on hills. Once worked up to speed it may show excellent power. Partly closing the needle valve will improve the power at medium speeds, but will reduce it somewhat at high speeds. If the float valve is too low, thc engine will start easily by priming hut will develop poor power at ordinary speeds. If the needle valve is opened this may be partly corrected, but at the cost of excessive gasoline consumption at high speeds. Generally speaking, if the gasoline level is materially too low, the power developed will be poor at almost any speed, and it will probably be hard to run slow in high gear. When the correct float adjustment has been found, thc needle valve must be very carefully adjusted. A sixteenth of a turn will make a vast difference in the power. Once properly adjusted, the engine will be very flexible to close the tank valve whenever thc engine is stopped.

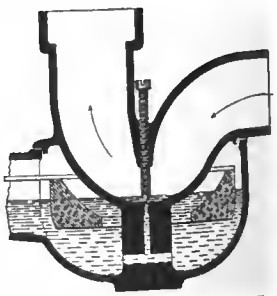

Fig. 4.—A "Puddle Type" Carbureter. A gasoline puddle in the base of the V-shaped mixing chamber is fed by gravity and is swept along by the stream. No lifting action is required of the gasoline, and a mixture is produced by very slight suction.

It is an excellent rule for thc amateur not to try to rush an adjustment. His first impression of the nature of his trouble may on further trial be found quite wrong. When he gets a fairly good mixture it is best to drive thc car a day or two, carefully noting its behavior, giving opportunity for the finer symptoms to show themselves, and giving himself time to analyze them critically before he attempts changes. If changes must be made on the road—other than in time expressly selected for that purpose—it is well to limit them to simple changes in needle valve adjustment.

LETTERS INTERESTING AND INSTRUCTIVE

MORE ABOUT THE GRADE QUESTION.

Editor THE AUTOMOBILE:

[1,549.]—Kindly pardon me for taking lseue with you on the grade questlon. I contend that the baee llne of meaeurement muet be the incline up which you are going, not the horizontal; 100 per cent. is etralght up and down; 100 per cent. muet be all there is of anything.

You want the grade of a certain hill. You provide youreelf with a 10-foot pole and a spirit level, go on the hill, and eelect an average grade. Lay down your pole and mark each end; bring tbe lower end up horizontal by the aid of the spirit level; measure up to tbe pole from the lower mark, perpendicular to the pole. This distance will give you a baels from which to figure the grade.

Take your diagram and measure up 110 feet. Have you got a 110 per cent. grade? Did you ever eat 110 per cent. of a pie? Please think tbis over and let me hear from you again.

Vergennes, Vt. A. D. EVARTS.

Your method is a perfectly good one, but it is not the one in general use. The difference is that you reckon by the sine of the angle instead of the tangent. Used with the ten-foot pole and spirit level, the method we gave is even simpler in

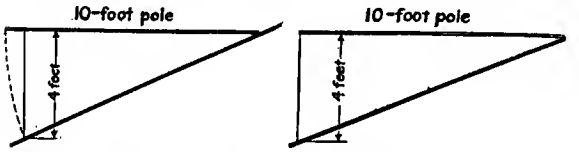

Diagram Illustrating Two Methods of Reckoning Grades.

application than yours. Rest one end of the pole on the ground and get it horizontal by means of the spirit level; then measure to the earth perpendicular to the pole, and the distance in feet, multiplied by ten, will be the percentage of the grade. By this method, of course, straight up and down is a grade of infinity per cent., which certainly is much closer to being "all there is of anything" than a mere paltry 100 per cent.

As to the percentage question, did you ever make 110 per cent. profit on anything you sold? We know some people who do. And though we may never have eaten 110 per cent. of a pie, we have eaten some that felt like it afterwards.

CONCERNING VALVE PORT ARRANGEMENT.

Editor THE AUTOMOBILE:

[1,550.]—In an engine with valves on opposite eides two porte are arranged for, but I underetand with valvee in the head only one port is used. Ie this correct? If so, bow is the port arranged for the inlet and exhauet gases? SUBSCRIBER.

Milwaukee, Wle.

All engines have two valve ports, one for the inlet and one for the exhaust, whether the valves are on opposite sides, the same side, or in the head. You are probably thinking of the Franklin valve system, in which the two valves are concentric and appear like one; but there are two ports there just the same.

IS A SMOKY EXHAUST EVER NECESSARY?

Editor THE AUTOMOBILE:

[1,551.]—I have noted recent Inquiriee on the eubject of lubrication, and while I do not intend to go further along the eame line, the question has euggeeted iteelf to me, whether it is ever necessary to run a car with a smoky exhaust from this cause, in view of the great amount of attention the emoke nuisance is now receiving.

Philadelphia, Pa. B. HARKER.

The only time it is necessary to use an excess of lubricating oil is when the engine is new, or when it is being put to an excessive strain, such as occurs in racing. Smoky exhausts are coming to be regarded more and more as an indication of carelessness and poor driving. We print elsewhere in this issue some advice from a prominent manufacturer of lubricating oil which should be interesting in this connection.

TO FIND QUANTITY OF GASOLINE IN TANK.

Editor THE AUTOMOBILE:

[1,552.]—I wae pleased to see in the September 17 ieeue of The Automobile an arangement for telling how mucb gaeoline there is in a tank, and thought I would send in my method for the benefit of your readers. I purchased for five cents in a drug etore a glaes pipe about 1-4 inch diameter with a 1-8-inch hole, and about 2 inches longer than the depth of the tank. By putting thie down into the tank and placing my finger over the top, then witbdrawing the tube, all the gasoline that entered the hole is held tbere by atmoepheric pressure, showing immediately the depth of the liquid in the tank. When the finger le removed, tbe gasoline runs out. I put two emall leather loops on the underside of my eeat over the tank, and push the glaee tube into them, where it le alwaye ready for use. H. B. P.

Hartford, Conn.

Your method is a very good one, infinitely to be preferred to the usual stick. A glass tube is frequently used in chemical experiments in this way to dip out a small quantity of a liquid, but we do not remember having seen it adapted to automobile use before.

CRITICISM OF TWO RECENT ANSWERS.

Editor THE AUTOMOBILE:

[1,553.]—I feel that I must take exception to two repliee which you made in last week's paper, first, which wae to J. M. Butler & Son, and, eecond, to party eigning "Brakes." Now, as I bave been a constant reader of your journal from its inception, I wisb it understood that I am anewering only in a friendly epirit, and feel it is my duty to do eo, ae botb answers are, ae given by you, incorrect, and I earnestly trust to see them corrected in your next lseue.

In regard to any modern two or four-cylinder touring car being able to travel eaeily at a speed ae low as 10 or even 5 miles per hour. I claim thie is imposeible on the high gear or direct speed, and is possible only with six-cylinder cars, uniees perfectly level or down grade le being traveled. I do except cars geared lower than the average custom and some light runabouts, but the average touring car when it gete down to 10 miles per hour with ordinary gear ratio of 3 to 1 on the direct drive, has its engine turning so elowly that if anything like a grade ie being ascended the car will positively not pick up without at least slipping the clutch, or is quite more likely to stall entirely, should occasion occur to quickly get out of the way of some team or paesing machine. You eay you do not understand where euch a question ever arose from. Please allow me to say that by making this remark you clearly ehow that you have never driven or rode with a driver to any great extent, otherwiee you surely would not have eo expreeeeu yourself.

Your answer to "Brakes," in which you eaid diseimilar metale are used in brakes because they possess a greater coefficient of friction, is aiso wrong, as a little reasoning on your part will clearly show from the fact that all plain bearings employ dieeimilar metale, euch as Babbitts, bronze, or some other alloy, in which rune a eteel shaft. If these metale poseeesed a very great coefficient of friction, they would not be used, a's you surely will admit in cbooeing materiale for bearinge friction is not eought for. A very plain experiment why dissimilar metals are used in bearings is thus: If we hold two comparatively coarse files together and try to move them back and forth, great effort is required; if one file le quite fine and the other coaree, the effort will be much lese. Now, should we view a finished shaft through microecope, same will be eeen to contain a very rough and irregular surface, the eofter materiai will aiso show a roughness, but of a much finer grain. The ehaft represents the coarse file and the soft metai the fine file. Now, the sole reason that metals of the eame kind are not used in brakee is because they would wear out too rapidly, just as they would if ueed for bearings, and a brake is nothing more than a large-sized bearing carrying a heavy load. Above illuetration appeare in George M. Hopkins' Experimental Science and other standard works above criticism.

Phoenixville, Pa. LEWIS T. RHODES.

If you will work out the exact number of revolutions per minute of the engine of a car geared 3 to 1, with 34-inch wheels, running ten miles an hour, you will find that the speed is probably higher than you thought.

$$\frac{5280 \times 10 \times 12}{1} \times \frac{1}{34} \times \frac{7}{22} \times \frac{3}{1} \times \frac{1}{60} = 296 \text{ r.p.m., approximately.}$$

Substituting 32-inch wheels for 34-inch wheels, the result is approximately 315 r.p.m. If you own a car with an engine in it which cannot run as low as 300 r.p.m. under load, we would advise you to get a new one. The minimum speed under load is usually taken at 150 r.p.m., and this was what we figured on in saying a car should run as low as five miles an hour on the high gear. As to our personal experience, we are willing to undergo any reasonable test, but we hardly think that enters into the question.

We admit that all plain bearings at present in use employ dissimilar metals, but the conclusions you draw therefrom are erroneous. Babbits and bronzes are used because their natural coefficient of friction is so low that their combination with a steel shaft gives less friction than a bearing in which both members are steel. A babbitt shaft in a babbitt bushing would give still less friction, but, unfortunately, shafts cannot be commercially made of this material. Your illustration of the coarse and fine files holds only in case the bearing is not lubricated, as with proper lubrication the oil forms a film between the two metals, and their surfaces do not actually come in contact.

We protest at your definition of a brake as a large bearing carrying a heavy load. How about the shaft bearing of an ocean-going steamship, two or three feet in diameter and carrying five or ten thousand horsepower? On the other hand, the coaster brake of a bicycle is only a few inches in diameter.

DIMENSIONS OF STRANG'S ISOTTA RACER.

Editor THE AUTOMOBILE:

[1,554.]—I would like to draw your attention to some inaccuracies which I do not think can be blamed on the typographer. The last issue of your usually excellent magazine had a statement which conflicted with a previous one so markedly that I had to compare the two. I will quote them and allow you to judge for yourselves.

On page 595 in the issue of April 30, describing the machines which took part in the Briarcliff, the first words are: "According to A.L.A.M. rating, Strang's Isotta was the highest powered machine on the course, its cylinder diameter of 145 mm. being equivalent to 5.7087 inches, which gives 55.1 horsepower." Further down, in the same column, concerning wheelbase: "Strang drove a 118-inch machine." In the table on page 597 the Isotta is credited with a bore of 5.7087 inches and stroke of 4.7245 inches. Now, in the issue of September 10, page 359, your technical editor states: "Strang's Isotta three-time winner has a four-cylinder engine, the dimensions of which are the metric equivalent of 5 7-8-inch bore by 5 1-2-inch stroke, rated at 60 horsepower." Further along: "The wheelbase is 122 inches."

Lastly, I would like to ask you which type of car Guyot drove in the French voiturette race—a single or a double cylinder. I know one of the Delages was a single cylinder and the rest double. On page 38, July 9, you say a double cylinder, and on page 84, July 16, you head an article "Single-cylinder 50-miles-an-hour Voiturette Winner." CHESTER S. RICKER.

Ithaca, N. Y.

We are unable to give you any authoritative figures as to the dimensions of Strang's Isotta, as the manager of the Isotta Import Company declines to make any statement on the subject. The official declaration of the bore at the time of the Briarcliff was 145 mm., equivalent to 5.7087 inches, as in the paragraph you quote, and this is doubtless correct. The figures for the stroke and the wheelbase were probably estimates.

Guyot's Delage was the single-cylinder one of the team. The error in the first article probably was made in the confusion attendant upon getting off the first cable reports after the race, and was corrected by the mail account in the next issue.

CONCERNING THE "3-PORT" 2-CYCLE MOTOR.

Editor THE AUTOMOBILE:

[1,555.]—Up to recently I have been under the impression that the two-cycle motor was a single type, but have frequently come across the term "three-port," and also note that some concerns advertise that their engines are absolutely "valveless," while others do not. Can you enlighten me on this point? INQUIRER.

Plymouth, O.

The two-cycle motor as largely employed in small marine work at first, was of what is known as the "two-port" type, in that a port is employed for the admission of the fresh charge, and another for the escape of the exhaust, while a check valve was used to imprison the mixture in the crankcase at the end of the suction stroke. In the "three-port" type, a port is used for the latter purpose as well, thus eliminating the check valve, making the engine valveless. It was found that the check valve constituted one of the greatest evils of what was known as the two-port engine, through the frequent uncertainty of its working, and when it was successfully eliminated by the use of a third port, the makers naturally sought to call attention to this advantage by terming the engine "valveless." There are some three-port engines which do not answer this requirement, though they embody nothing in the shape of a valve as present on the four-cycle type. In strict terms, however, a port covered or uncovered by the piston is as truly a valve as the usual poppet type.

ONE WHO CAN DRIVE AT FIVE MILES AN HOUR.

Editor THE AUTOMOBILE:

[1,556.]—"The Lowest Speed of an Automobile," is noted in your issue of September 10. I have a Franklin runabout, and on bad roads, such as the Plank Road between Jersey City and Newark, I run at a rate of less than five miles an hour. A short time ago when in Connecticut I went astray, and in taking a short cut to get back to the right road, I went over a road so rough and hilly and sandy that if the road to Hades is anything like it there will be no travelers that way. I drove sometimes on first and sometimes on second speed, and, when I could, on high. On high gear I did not go over five miles an hour, usually four, or even less. At the end of a 55-mile trip the engine was running easily and sweetly, with nothing overheated.

Be good to the engine and you will be good to the whole car, tires included. Overload the car and overwork the engine, and you won't have to get out of the car to look for trouble; it will come to you. Some people know well enough that two locomotives are often required to pull a train, and yet seem to think there is no such thing as overload to the engine of an automobile. I am told I am lucky, but I am just good to the beast, and the beast is good to me, that's all. GEORGE E. LONG.

Jersey City, N. J.

TRUE STORY OF THE DARRACQ LITIGATION.

Editor THE AUTOMOBILE:

[1,557.]—A few weeks ago there appeared in your publication an article relating to the court proceedings brought by some stockholders against A. Darracq & Company, Suresnes, France, asking for the dissolution of that company. Upon making inquiries of the company regarding this matter I was officially informed by the chairman of the board of directors as follows:

"The articles you refer to relate to some proceedings taken by a few stockholders in France at the instigation of the Marquis De Dion to have it declared that A. Darracq et Compagnie is irregularly constituted under French law. The judgment of the French Court was given on August 5, when the proceedings were dismissed and the claimants condemned to pay the expenses in addition to 5,000 francs damages, for bringing an action without reasonable motives, the Marquis De Dion being personally condemned in 1,000 francs damages. The Court intimated that a higher damage would have been given, but it thought the injury to the company had been more moral than actual. If you could get this result inserted in any of the papers which have noticed the matter I should be much obliged."

I should be very glad to have you give this the necessary publicity in the next issue of your magazine.

G. M. MACWILLIAM,
New York City. Darracq Automobile Parts.

A HELPING HAND FROM MONTANA.

Editor THE AUTOMOBILE:

[1,558.]—Noting letters 1509 and 1515 in the issue of August 20, I think I can help the inquirers. With regard to the first, would call the attention of the two writers to a book advertised in your columns that is certainly all that one could ask for if he is looking for good, practical information with regard to the automobile, namely, "Self Propelled Vehicles," by J. E. Homans, at $2.00. Possibly this book would cover the ground that is required. This is certainly the best treatise I have seen and I have quite a number.

As to letter 1515, possibly one of the following firms may be able to fill the bill for Mr. Carruthers: E. F. Hodgson, P. O. Box 112, Dover, Mass.; Springfield Portable Construction Co., 57 Waltham avenue, Springfield, Mass.; North American Construction Co., Bay City, Mich. "GLAD TO HELP."

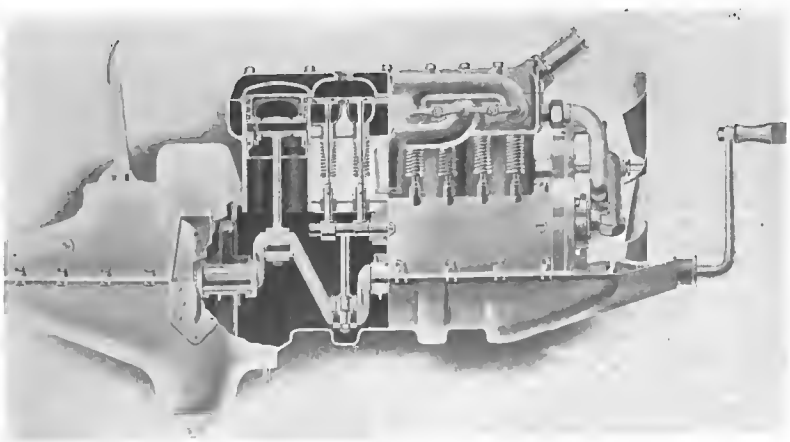
Butte, Montana.

WHEN the now familiar Ford runabout appeared three years ago, the Ford Motor Company announced that it would soon bring out a light touring car at a correspondingly low price. Work on this model has been going on steadily ever since. The car was ready last January, but it was decided to test it in actual service before putting it on the market. The cars built at that time have now been in use over nine months, giving opportunity for improvements and refinements as occasion was found for them. While the general appearance of the touring car recalls very strongly the runabout, it is nevertheless an entirely distinct design. The stroke of the engine has been lengthened to 4 inches and the layout considerably changed. There is also an entirely new system of rear spring suspension. The wheelbase is 100 inches, weight 1,200 pounds, and the price $850. Deliveries begin October 1.

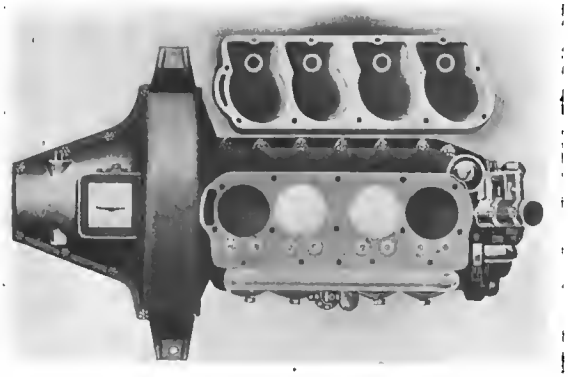
Motor.—The motor of Model T—as the light touring car is officially designated—is, of course, a four-cylinder, four-cycle, and is rated at 20 horsepower. Bore and stroke are 3¾ and 4 inches respectively. The cylinders are cast in one block, with the water jackets and the upper half of the crankcase integral; but the water-jacketed cylinder head is an entirely separate unit, easily removed when desired for cleaning, adjusting, etc., with the breaking of but one connection. The advantages of this design are obvious; anyone who has had to clean the carbon out of a cylinder or grind in a valve on a motor of the usual construction will recognize them immediately. By removing 12 bolts, all four cylinders and pistons and the eight valves are instantly accessible. The disadvantage appears to be that it introduces a ground joint in each cylinder head. It should be remembered, however, that the two smaller joints in each cylinder, for the valve covers, are eliminated. Further, this design lends itself admirably to the scheme of water circulation. There is one inlet, at the front of the cylinder casting, and one outlet, at the front of the head casting; but the only communication between the jackets of the cylinders and those of the heads is at the extreme rear, so that the water is forced to circulate through all parts of the jacket, and cannot by any possibility "short-circuit."

All valves are on the right-hand side and are actuated from one camshaft, which is cut from the solid with cams integral. The push rods have flat, mushroom ends to bear on the cams. The inlet and exhaust manifolds are separate and are held to the cylinder casting by four yokes and bolts.

The upper half of the crankcase, as mentioned above, is of cast iron integral with the cylinder block; the lower half is of pressed steel, extending back under the flywheel and change-gear, and forward to support the starting crank. It touches the frame at three points, and carries the entire power plant. The first point of suspension is at the bearing of the starting crank, the extension of the case resting on the middle of the front cross member of the frame; the other two points are one on each side of the flywheel, where pressed steel brackets, riveted to the case, extend out to the frame members on either side. It will be noticed that the lower half of the case is not, as usual, a mere oil pan, and cannot be removed without removing the whole power plant from the frame; instead, access to the connecting rods is provided through large hand-holes in the upper part of the case, on the left side. Flywheel and change-gear are completely enclosed by the pressed steel case underneath and a light cast cover above.



Complete Power Plant of the Ford Touring Car, in Partial Section.



Motor from Above, with Cylinder Head Casting Removed.

Motor Accessories.—The carbureter is a new design float-feed automatic, with a quintuple ball air valve. The valve is controlled by a small lever on the dash, so that it is possible to make all adjustments from the seat. The gasoline tank is cylindrical, of 10 gallons capacity, and is mounted directly on the frame under the front seat.

One of the most radical features of the new car is the ignition. This is by magneto exclusively, and the magneto is embodied in the flywheel as an integral part of the motor. It has no commutator or brushes, no gearing, no contact points, no moving contacts, no moving wires; the rotor is a part of the flywheel, and the stator, carrying the coils in which the current is generated, is a stationary spider carried on the inside of the flywheel casing. The slightest movement of the flywheel generates current enough to make a powerful spark. The timer is mounted on the front end of the camshaft, and the spark coils and switch are on the dash.

The water-cooling system consists of a vertical-tube radiator of the same familiar design as used on the runabout, an eight-bladed fan and a centrifugal pump. The fan and pump are mounted on the same shaft, the former, of course, in front, and are driven by a pinion meshing with the two-to-one gear; they are supported and centered by bolts projecting from the gear casing. The direction of the water circulation through the cylinder and head castings has already been described. Piping is almost completely eliminated, there being only three short connections—bottom of radiator to pump, pump to cylinder casting, head casting to top of radiator.

Lubrication is entirely by splash. The lower part of the pressed steel casing which encloses the crankcase, flywheel and change-gear is filled with oil. The flywheel, revolving in this oil, throws it against the sides and top of the casing into ducts which feed front and back to the motor bearings, the gears and the universal joint. Each connecting rod big end dips into a separate oil well and splashes oil to the pistons and cams. All overflow from these wells returns to the large well under the flywheel.

Transmission.—The change-gear is of the planetary type, which the Ford Company has always persistently advocated. It gives two speeds forward and a reverse. On the high speed the whole weight of the gear revolves with the flywheel; on the low speed and reverse the planetary gears and pinions come into action, but as none of these are of the internal type, there is very little noise or vibration. The clutches are low speed and reverse are fiber-lined steel bands; these grip their drums smoothly, and when released spring away, insuring positive action and no waste of power from dragging. A third band forms the foot brake. The high-speed clutch is of the multiple disc type, so designed as to give the maximum bearing surface, and running in an oil bath. The reserve power and flexibility of the motor call for very little use of the gears. The low speed is rarely used except for the first 20 or 30 feet, when starting from a standstill; on the high speed the car can climb any ordinary hill and run at from 3 to 40 miles an hour.

From the change-gear the power is transmitted through the single universal joint and the drive shaft to the bevel gears on the rear axle.

Running Gear.—The rear axle is the usual live type, and is combined with the torsion tube, which encloses the drive shaft, according to the Ford "three-point system." The front end of the torsion tube forms the ball of a ball and socket joint, the socket being firmly supported by the rear end of the pressed-steel undercasing of the power plant. This tube transmits the entire driving thrust from the axle to the frame, none of it being taken by the springs. Moreover, the tube is braced by two other lighter tubes, which extend from behind the ball and socket joint diagonally to the rear spring seats on the axle, so that it is not necessary to make the parts of abnormal size to insure rigidity. The universal joint of the drive shaft is, of course, centered inside the hollow ball of the joint. By this construction the rear axle has perfect freedom to adapt itself to the road surface, while the rear spring system may be made light and flexible and its resiliency fully utilized.

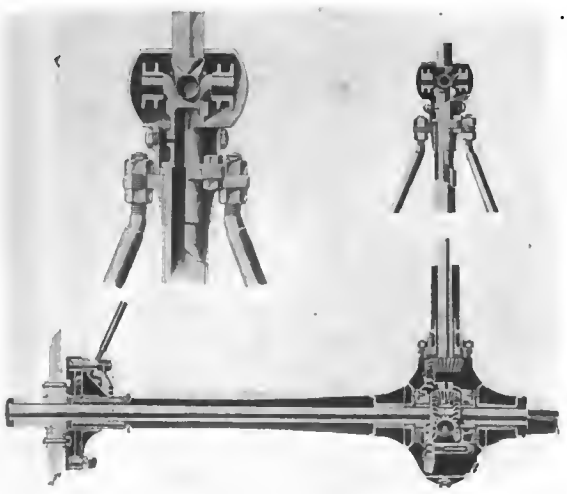
This construction is practically repeated in the front axle. Here there is no transmission of power to be cared for, but similar brace tubes run from the spring seats and meet in a ball joint carried by the steel undercasing at a point just forward of the flywheel. The axle itself is a one-piece forging of vanadium steel, and is straight from spring-seat to spring-seat.

The entire spring system consists of but two semi-elliptic springs, one in front and one in rear, both inverted and transverse. Their ends are shackled on the axles close to the wheel hubs, and at the middle they are held to the front and rear cross-members of the frame, respectively, by stout steel straps. The cross-members are of an inverted U-section, in which the springs fit snugly. The attachment of the front spring is well shown in the front quartering view of the car with landaulet body. One advantage of this arrangement is that the weight of the car is brought out close to the wheel hubs, thus relieving the axles of much strain.

The wheels are artillery, with 12 spokes, 30 inches in diameter. The rear wheels are keyed to the ends of the live axle shafts; the front ones run on ball bearings. Tires are 30 x 3-inch front and 30 x 3½-inch rear.

Control.—Perhaps the first thing that the average driver would notice on seeing the car is that the steering wheel and levers are on the left-hand side. This arrangement has been frequently tried and as often abandoned; its adoption on this car certainly shows the Ford Company's unwillingness to be bound by any tradition. Theoretically, of course, since vehicles meeting on the road pass to the right, the

The Ford with Landaulet Body, for Taximeter Service.



Ford Three-Point Drive System—Rear Axle and Joint.

driver should sit on the left, so that he may see the road beyond. This involves the disadvantage that he must operate the side levers with his left hand, which many people find extremely inconvenient. However, on the Ford these levers have the simplest possible forward and back movement, and are rarely used except for starting and stopping. One controls the high speed forward and the reverse, the other the emergency brakes, which are internally expanding on the rear hubs. Two pedals operate the slow speed forward and the service brake respectively.

The steering column is raked at a sharp angle and carries the irreversible gear at its top, in a small circular case just under the wheel. The throttle and spark levers are mounted on the column on the right and left, respectively, where they can be reached by the index fingers of each hand, without releasing one's hold on the wheel-rim.

Bodies.—The standard light touring body seats five persons comfortably. Its lines are simple and graceful. well accentuated by molding. The hood retains the runabout design, square with beveled corners, and harmonizes perfectly with the body. Practically the entire weight is carried between the axles, the rear seat overhanging very slightly and the hood not at all; this is permitted on the comparatively short wheelbase—100 inches—by the unusually compact motor. No announcement has been made regarding colors or finish.

In addition to the touring car body, the chassis will be supplied with coupé and taximeter cab bodies, listing at $950 thus equipped, and with private town car bodies at $1,000. These will be ready November 1. Runabout and roadster models will be announced later.

Vanadium Steel.—This material is used for all shafts, gears, axles, springs, and many smaller and comparatively unimportant parts. The alloying of steel with vanadium has only recently become commercially possible. Until within three years ago the world's output of the pure metal was less than 200 pounds a month; in consequence its price was many times that of gold. But since then a large deposit of vanadiferous ore has been opened up in South America, and it is now on the market at about half the price of silver. As it is used only in "homeopathic doses," vanadium steel can be made at about the same cost as the best grades of chrome-nickel steel. It machines as easily and uniformly as low-carbon steels, and works beautifully under the forging hammer and dies, while in dynamic properties it is claimed to be much superior to any product hitherto tried. Its use throughout the car is a point on which the Ford Company lays great emphasis.

A BUDGET OF NEWS FROM THE PINE TREE STATE

PORTLAND, Me., Sept. 21.—With the coming of September the summer season in Maine may be said to be over. It has been a very successful one in the automobile industry, better than was expected in view of the great financial disturbances of last October. All during last winter there was much talk among prospective buyers, for the financial stringency did not seem to hit this section very heavily. Cars of all kinds sold readily in Maine this year, but the smaller type seemed to be in much the greater favor, though the large touring cars were not by any means neglected.

During the past season there have been hundreds of visitors to the State. Complaints have been general in regard to the conditions of the roads in the western part of Maine, but once east of Portland, the tourists have had few kicks to register. The Glidden tour and the Ideal tour, both of which passed through Portland, proved the main events of the year.

Registration Figures Tell a Story.

No better idea of how the automobile trade has grown can be obtained than from the figures of registration at the office of the Secretary of State in Augusta. From the figures on file it is learned that the total amount received in fees for the registration of automobiles from the time the law went into effect, June 1, 1905, to September 1 of the current year, was $6.108; from licenses issued to operators, $7,126; from registration of motorcycles, $662; from licenses issued to dealers, $790; making a grand total of $14,686.

As might be expected, the business for the past month approaching as it does the latter part of the season, shows a falling off compared with that of some of the other months of the year. The number of automobiles registered during August was 93; the number of licenses issued to operators was 113; one license was issued to a dealer and twenty motorcycles were registered. The amount received in fees was as follows: Registration of automobiles, $186; licenses to operators, $226; dealers' licenses, $10; registration of motorcycles, $40, a total of $426.

The total receipts in fees for the past eight months of the current year are as follows: Registration of automobiles, $1,632; for licenses to operators, $1,862; dealers' licenses, $200; registration of motor cycles, $206, making a total of $3,900.

An index of the rush during the spring is obtained from these figures of the registration of automobiles during the first eight months: January, 8; February, 6; March, 36; April, 129; May, 169; June, 297; July, 168; August, 93.

Licenses to operators during the same period were issued as follows: January, 9; February, 5; March, 35; April, 135; May, 190; June, 230; July, 214; August, 113.

In the registration of motorcycles no applications were received until March, when four certificates were issued. Monthly registrations since that month have been as follows: April, 24; May, 17; June, 18; July, 20; August, 20. The number of licenses issued to dealers during the past eight months was 22.

A Rush of Hunters to the Maine Woods.

Every year an increasing number of automobile parties passes through the lower part of the State bound to the hunting camps in the northern woods. Many of the machines carry full camping outfits, including tents, cook-stoves and provisions. The roads are none too good, but this only furnishes an additional spice of adventure.

LAMPS WITH BESNARD SYSTEM OF ECLIPSING.

By RICHARD H. WELLES.

The use of acetylene gas for use in automobile headlights is undoubtedly the most popular form of light for automobile use at this time. Their efficiency in the country, where a long and penetrating beam is necessary, has been proven satisfactorily, but for city use they have been a constant source of criticism

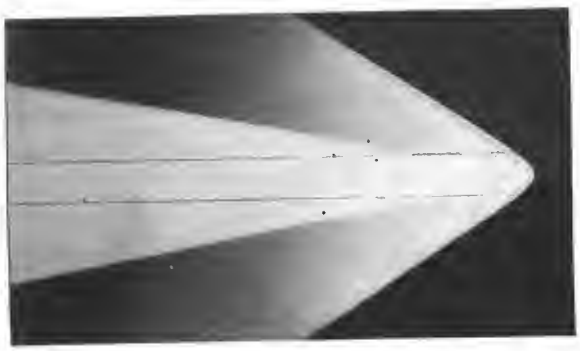


Fig. 1.—Showing double rays and two distinct fields of light.

because of the blinding glare coming from the parellel beam of the lens reflector. This objectionable feature has been overcome in the Solarclipse lamps, manufactured by the Badger Brass Mfg. Co., in this country. Several bills are up before the different State legislatures which, if passed, will compel the user to adopt a lamp embodying the "eclipsing" feature.

The Besnard system has been very popular abroad, and the United States patent rights are now owned by the Badger Company. This system seems to have solved the problem of headlights, for in this lamp are embodied all the essentia ldetails of the popular Solar light, besides having an arrangement attached by which the longer and blinding rays may be shut off at will by simply working a lever on the dashboard. Acetylene lamps for road use have two sets of rays, one from the lens mirror—the objectionable one for city use—and the other are the diffused or short distance rays, coming directly from the flame. If the long, penetrating rays could be shut off we would find that the shorter rays would answer every purpose for city streets. This the Solarclipse lamp and shutter does.

The manner in which the light is distributed may be seen in Fig. 1, which shows the double rays—two distinct fields of light. The first are the more intense, parallel, or long-distance rays, more powerful, and of greater utility to the driver, but blinding to the approaching road users. These rays consist of the rays

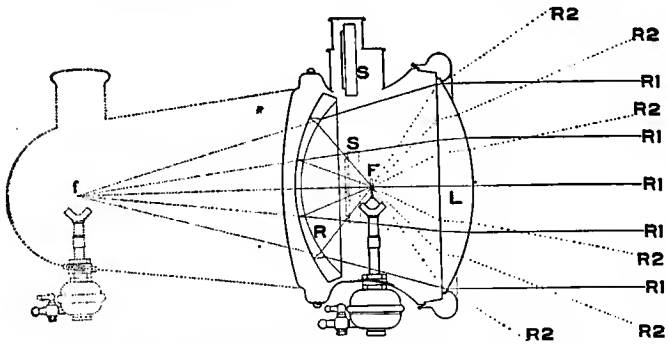

Fig. 2.—Showing special combination of the hyperbolic curve of the reflector and the plano-convex lens.

of light which eminate at the back of the flame *F*, and, striking the reflector *R* of hyperbolic curve, are reflected and directed against the plano-convex lens *L* in front of the flame, by which they are focused and refracted in long parallel rays of great penetrative power, shown by the lines R^1, Fig. 2.

This special combination of the hyperbolic curve of the reflector and the plano-convex lens permits the use of a lens of large diameter and long focus in a comparatively small lamp, see Fig. 2. The dotted lines back of the reflector in Fig. 2 show the depth of lamp that would be necessary to obtain a like powerful result if we did not use this patented hyperlenticular combination. The second are the diffused or wide, short distance rays, produced by th light rays, which eminate from the front of the flame, and are thrown directly on the plano-convex lens. These rays, magnified and rendered much clearer by the lens, diffuse at a wide angle at the side of the vehicle, as indicated by the dotted lines *R 2*, Fig. 2, and are not blinding to anyone approaching. Refer again to Fig. 1, and eliminate the lighter or narrow ray. The remaining field of light after the long-distance ray has been eclipsed will plainly appear. This wide beam of light now thrown by the headlight extends about 35 yards, and gives perfect front and side illumination.

When the shutter (*S*, Fig. 2) is up in the heat hood, held there by a spring, the light from the lamp is ready for the road, but by working the lever on the dash the spring is released and the shutter comes down, eclipsing the effect of the lens mirror at the back.

The mechanism which operates the shutter consists first of the operating lever at the back of each lamp (see Fig. 3) which,

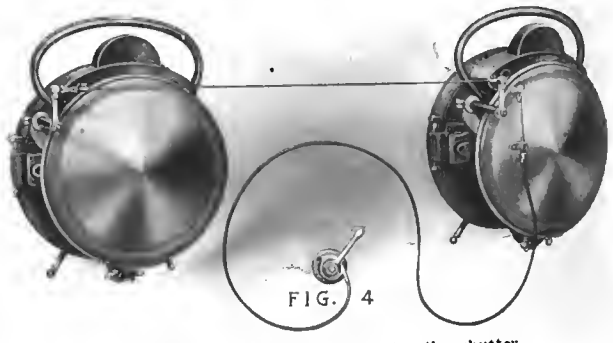

Fig. 3.—Mechanism which operates the shutter.

when pulled down, brings the shutter into eclipsing position. For use on a machine, so that the two lamps may be operated at once, the levers, of the two lamps, are connected by a piece of piano wire. By the use of Bowden flexible wire the right-hand lamp may be connected to any convenient place on the dash or the steering post.

EXAMINATION OF PREMIER CENTURY CAR.

INDIANAPOLIS, IND., Sept. 19.—After eight hours of careful and thorough examination of the Premier "100 miles for 100 days" car, David Beecroft and Berne Nadall, of the Chicago Motor Club, reported that every part examined was found to be in exceptionally good condition. Not a single case of breakage or distortion due to faulty workmansbip or design was discovered.

The members of the technical committee were passengers in the "Century" car on the last 100 miles, and were told to take charge of it for that day. At the completion of the test, which took place at Michigan avenue and Twenty-third street. Chicago, the two odometers showed 12,189.6 miles and 12,246 miles respectively. The last 43 miles was made use of by the committee for observations on the running and general performance of the car, partly over boulevards and partly over rough country roads. An excellent opportunity was afforded for noting the working of the motor, the efficiency of the brakes, and the general stability of the car. There was not a single indication of looseness or derangement in the running gear or steering.

After the end of the run the car was completely disassembled and all the working parts were examined. The final conclusion of the committee was that the car could endure a repetition of the same mileage without the necessity of overhauling.

HOW ORVILLE WRIGHT'S AEROPLANE FELL

WASHINGTON, D. C., Sept. 21.—Wright brothers' aeroplane, which everyone believed would be bought by the United States government, September 28, lies a pile of broken sticks and torn cloth in the hangar at Fort Myer, Va. A guard watches over the remains and warns with the danger of court-martial anyone who wishes to enter the building. The man who has stood in the world's limelight for the past two weeks, who has been accepted the world over as the subjugator of the upper air, lies in the post hospital, so severely injured that he may not be on his feet again for twelve weeks. Lieut. Thomas E. Selfridge, of the Fifth Artillery, has with his life paid the first toll of the government for success in aerial navigation.

Like those of the public fortunate enough to see the Wright aeroplane aloft, the United States government, represented by the Secretary of War and the Board of Tests of the Signal Corps, feels satisfied that the acroplane that came to earth is a success. The government wants another like it, and Orville Wright will deliver it. But the inventor, lying in the hospital, already sees where he can improve the type of the aeroplane, and he will be thinking and planning the three long months that he must lie inert. Then we may expect something better.

In the meantime, the Board of Tests expects that along will come A. M. Herring, from his shop off Broadway, about Sixty-sixth street, New York. He is due in Washington October 13. The government expects him with a great deal of interest, for much has been written about him, and he himself has said much about his ability to navigate the air successfully—automatically, he would have us believe.

That this terrible catastrophe of last Thursday will retard aviatory progress for some time, those who see below the surface do not believe. Wilbur Wright, with a machine almost identical to that of Orville, will not delay his demonstrations abroad. The followers of sky motoring consider this accident to be an incident of success, and will act accordingly; that is to say, the work will go on almost as if nothing happened.

It would require a volume to enumerate with explanations the theories that have already been advanced as to just how the break in the propeller occurred, and the causes. All that anyone knows is that the accident was caused by a broken propeller, except Wright; for he probably has figured it out. It is on what Wright said, shortly after his wounds were dressed, in word that he sent to his elder mechanic, Taylor, that the following opinion is based.

Wright said: "Look at that transmission."

There is no "transmission" on the aeroplane such as we have on the automobile. In automobile parlance, Wright would have said the "drive." For he referred to the two chains, one longer than the other, that transmit by chain the power of the motor from the crankshaft to the propeller shafts, one on each side of the afterpart of the aeroplane. These chains cross each other in performing their functions. Not an expert on aviation has seen this feature of the Wright brothers' flyer for the first time but that he has exclaimed, "Oh, cross-chain drive!" One can readily see that the crossed chains had a tendency to pull the propellers together. After the machine struck the ground it was found that the shaft of the broken propeller was badly bent inwards, that is, toward the opposite propeller. The angle-iron that had supported it was almost completely loose, and entirely from the bottom fastening.

The propellers used were not "new," except in the sense that they had not been used before at Fort Myer. They had been tested previous to the fatal run. But they were each eight inches, some say a foot, longer than those used for the record flights that made the world believe in the simple-looking machine.

From the appearance of the fracture there seems to be no way in which the accident could have occurred unless this angle-iron loosened, allowing the propeller to slip inward, drawn by the chain. The other propeller, driving toward it and upon it, snapped off the end, and the spectators saw something that looked like a piece of paper flutter down to earth.

Wright heard and felt the shock, perhaps; at any rate, he reached for the cord above his head and shut off the gas supply of the motor. Then he apparently endeavored to glide down to the earth. For 40 feet, perhaps, he was partially successful. He said afterward to Taylor that if he had been twice as far from the ground he would have been able to regain control of the machine and to have landed easily on the skids. But this does not seem probable, for the aeroplane at the time of the accident was slightly inclined to manoeuver a turn. When Wright lowered the front balancer for the down glide, the machine seemed to slip off sideways in the air, at an angle of 25 degrees. Thirty-five feet from the earth it swung around on its already begun turn, and at the same time pointed more directly downward, so far, indeed, that the surfaces of the superimposed plans no longer pressed against resisting atmosphere. Finally, these planes were at right angles with the ground, the port end nearest the earth, the forward balances straight out ahead. It is probable that the port side and the forward balancer struck earth first and perhaps minimized, though slightly, the force of the contact for the main body of the machine, carrying Selfridge and Wright.

The passengers could not have jumped from the machine on account of the cross wires hemming them in on all sides. They might have slipped down between the wires and their seat, but there could have been no advantage in it, and they probably did not attempt to do so. When found, Wright's arm was about Selfridge. It appeared that he had endeavored to hold the lieutenant in the seat before the crash came, but as the machine came down head-on, the men probably left their seats, were pressed against the wires, while the apparatus fell on top of them.

HOW WILBUR WRIGHT IMPRESSES THE FRENCH PUBLIC

LE MANS, Sept. 17.—We are on the eve of great doings here. Wilbur Wright has been progressively training for flights that it is firmly believed by his followers will eclipse all previous records in heavier-than-air experiments. His best performance up to date is 19 minutes 48 2-5 seconds, made at an average height of 40 feet and over a distance estimated at 14 miles. The flight was made in the early morning in perfectly calm weather, Leon Bollee, M. Landry, Paul Jamin and Baron de Sennevoy being present to officially time the performance. There was apparently no reason why Wilbur Wright should have come down; his engine was running well, his gasoline supply was plentiful, and his handling of the machine was perfect.

Later in the day a second flight was commenced, but after 3 minutes 21 seconds in the air a gust of wind struck the aeroplane and carried it towards a group of trees. Wilbur Wright sought to overcome the shock; he raised the apparatus, attempted to turn short, but did not succeed, the left wing striking the ground. The engine was still running, but Wilbur Wright immediately cut out and settled down on an even keel a little more roughly than usual, it is true, but without inflicting any damage. When heeling over, however, the wing had suffered somewhat, the one which came in contact with the ground being the same that had been damaged on the racecourse a few days before. A couple of days will be required to make the necessary repairs,

after which it is confidently believed that an attempt at long flights will be made.

There is a Wright and an anti-Wright camp in France, the former believing that the American aeronaut has left all other experimenters far in the rear, and the latter party persisting in dubbing him a bluffer or an acrobat. There has been a change of opinion in the various newspapers regarding the stranger from Dayton. When the first flights were made the praises of the Yankee were chanted in chorus: the others were children, they had been merely playing at flying, they went aloft like a scared hen, they were incapable of action in a wind. Now that has changed and the criticisms are being directed towards the retiring aeronaut at Le Mans. It being impossible to deny that Wright knows how to fly, the criticism is put forth that his machine can only be managed by a person having gone through a long period of training, that it is too slow, and that no improvements have been made on it for several years. Probably the explanation of most of the journalistic criticism can be found in the fact that after the first favorable accounts Hart O. Berg neglected to hand out publicity money. When the broad hint was given that there should be some recompense for so much favorable comment, the equally broad reply was given that no comments were asked for and none would be paid for. Since then certain journals can see nothing good in the Wright brothers' apparatus.

Wilhur Wright Unofficially Breaks Time Record.

LE MANS, Sept. 21.—This afternoon Wilbur Wright took the world's record from his brother with a flight of 1 hour, 31 minutes, 51 seconds, covering a distance of about 60 miles. After three false starts the machine was successfully launched at 5:15. He at first showed unusual prudence, flying so low that he seemed almost to skim the earth, but on the thirteenth round he rose to a height of about 60 feet. The sun was just setting and the aeroplane made a picture which time and again drew cheers from the 10,000 spectators. In the gathering darkness the machine kept steadily on, with the regularity of an express train. Not until long after night had fallen did Wright shut off his motor and come lightly to the ground. The official measurement is only 66.6 kilometers, being taken between the flags at the ends of the field; in reality the distance was greater. That part of the flight before sunset, 53 minutes, is acceptcd in the contest for the Michelin prize.

A FRENCH NATIONAL AERIAL LEAGUE TO BE FORMED

PARIS, Sept. 17.—All France is alive with enthusiasm for aerial navigation. The public interest in balloons, dirigible airships, aeroplanes, aeronautical motors and their auxiliaries is patent to any observer; a further and more convincing proof of the desire of the French nation for supremacy in the air is to be found in the formation of the National Aerial League, a body founded by some of the most distinguished aeronauts and their supporters in France, and which, it is hoped, will group together hundreds of thousands of French citizens. The object of the league is declared to be to encourage aerial navigation in all its forms. With the funds provided by members it will hold competitions for acronautical motors, the forms of aerial propellers, researches in the best forms of aeroplane wings, long-distance flying competitions, etc., in a word to encourage by means of conpetitions and prizes, every form of aerial navigation.

To make the leaguc truly national, the annual subscription has been fixed at one dollar per membcr. On such a basis it is estimated by the organizers that 50,000 members will be obtained during the first month of existence of the league, giving a working fund of $50,000. In addition to ordinary members, life members are received on payment of a substription of not less than $20; special prizes, to be named after their donators, will be offered whenever a sum of not less than $200 is paid into the treasury.

Those responsible for the formation of the league are M. Deutsch de la Meurthe, M. Archdeacon, Armengaud, and Quinton, all men who have already contributed large sums towards aerial competitions. Leading aeronauts interested in the league comprise Farman, Delagrange, Bleriot, Levavasseur, Esnault-Pelterie, Capt. Ferber, Julliot and Kapferer.

DELEGRANGE MAKES A NEW EUROPEAN RECORD

PARIS, Sept. 17.—For the present the European aeronautical record stands at 29 minutes 53 4-5 seconds, obtained by Leon Delagrange at Issy-les-Moulineaux. What it will be in seven days from now it is impossible to say, but it is practically certain that it will be still higher than at the present moment. Already the arrival of the news of the flight of more than one hour by Orville Wright has quickened European aeronauts to greater activity.

Leon Delagrange's record was made in the early morning in the presence of Captain Ferber, Achille Fournier, Rene Gasnier and others. Almost as soon as the Antoinette motor was started up the biplane apparatus rose in the air and made fifteen and one-half circles around the field, covering a distance estimated at 15 1-8 miles before gently scttling down to the ground with its five-gallon gasoline supply exhausted. The performance beat the record of Henry Farman with 20 minutes 19 3-5 seconds at Issy on July 6.

The following day Delagrange attempted to beat his own record, but again, owing to lack of fuel, just fell short of half an hour, his time aloft being officially certified at 28 minutes 11-5 seconds. Preparations had been made for a longer flight, but this was rendered impossible by a leakage from the gasoline tank, the apparatus being obliged to come to earth after a most successful flight in a rather strong wind.

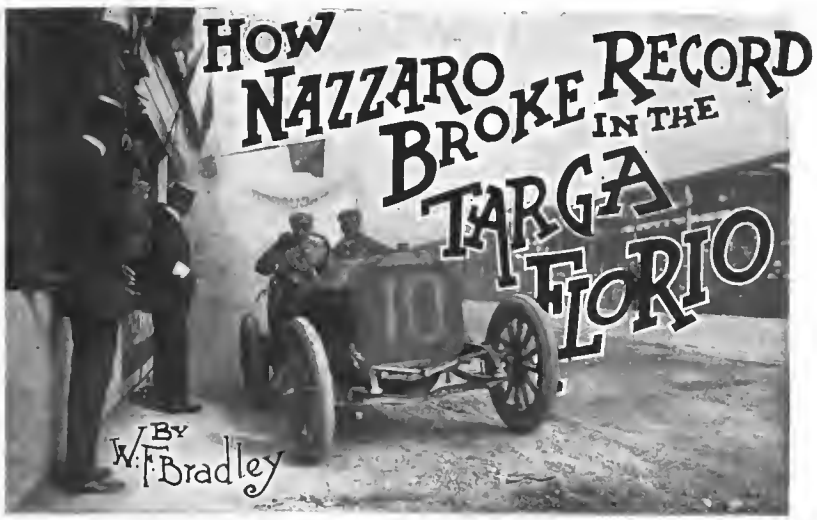
French aeronauts are now anxious to make an hour's records, and both Delagrange and Farman will train every day with this objcct in view. The newly-formed National Aerial League has offered a special money prize of $200 to the first French aeronaut who will double Wilbur Wright's present record of 19 minutes 48 2-5 seconds.

"REPUBLIQUE" OFFICIAL TEST SUCCESSFUL.

PARIS, Sept. 17.—*Republique*, the government dirigible airship, has completed all her official tests and trials and will be deflated in a few days in order to allow her place to be taken in the shed by Lebaudy to be fitted out as a training ship. The last trip of *Republique* was a voyage of eight hours, during which she evolved for a long time over Paris, then sailed off to the northeast to Compiegne, where further evolutions were made.

PREPARATIONS FOR INTERNATIONAL RACE.

BERLIN, Sept. 17.—Preceding the Gordon Bennett aeronautical race, scheduled for Sunday, October 11, there will be an official reception by the German Aeronautical Federation at Berlin on October 9, and on the following day a long-distance and a landing competition. The start of the international race will be at Schmagendorf, in the suburbs of the city, to which spot all balloons and material must be dispatched not later than October 8.



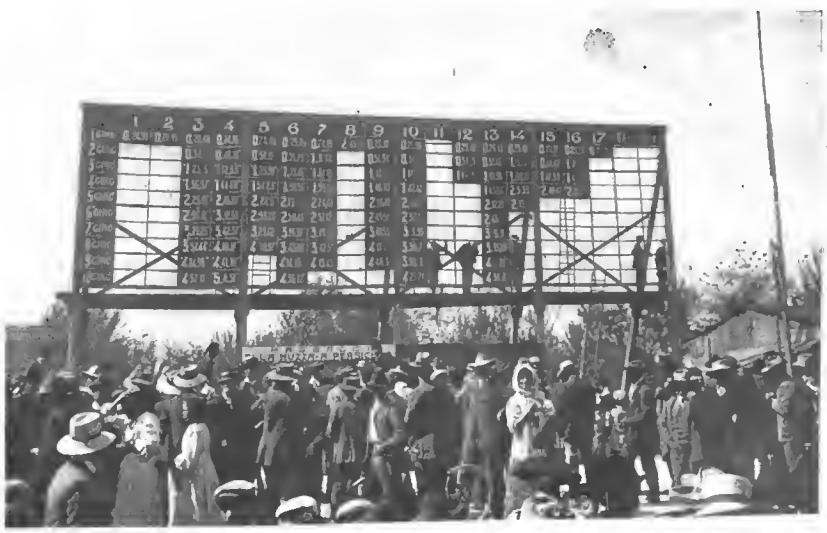
Nazzaro Halts In Front of the Grand Stand to Confer with Officials.

BOLOGNA, Italy, Sept. 6.—Felice Nazzaro has abundantly proved that the setbacks of the opening part of the season were but a temporary clouding of his brilliant career. By this Sunday morning's performance on the flat course in the neighborhood of the old world town of Bologna he has won the Florio Cup and the Coppa d'Italia for Fiat, the Cup of the Automobile Club of Genoa and the Targa Florio for himself. In addition to the quadrette of cups and the bag of gold to which he is entitled, Nazzaro has the satisfaction of beating all existing records for long-distance speed on roads. The 328.2 miles were covered to-day in 4:25:21, which is at the rate of 74.3 miles an hour. The previous record was 70.61 miles an hour, also established by Nazzaro, in the Grand Prix of 1906.

Not only was the race the fastest ever run, but it was one of the most interesting and keenly disputed that Europe has known. There were seventeen starters, representing two Italian firms and four French, all using the special 155-millimeter bore cars built for and run in the Grand Prix at Dieppe. Germany having kept out of the affair, the race resolved itself into a dual between the Fiats and Italas, which had failed to make a good exhibition in the earlier race, and the Lorraine-Dietrich, Bayard-Clement, Mors and Motobloc—all French—which had failed to hold the French trophy for the land of the tricolor. In their own exaggerated language, each was for "revenge"; it was Italy that finally got it, after a magnificent fight.

Duray, as irrepressible as ever, first shot over the line on his big blue Dietrich, regarded as a stout champion for France. Gauderman, driving a Motobloc, failed to evoke a cheer, the best that was expected of him being a regularity display. Demogeot, the big cool-headed driver of the Mors, carrying No. 3, had plenty of partisans, though it was known that his car was two or three miles an hour slower than some of the others. Lancia, of course, evoked a roaring cheer as his Fiat shot away, followed a minute later by Gabriel on the Bayard-Clement, generally admitted to be the fastest car of the whole group. Cagno took No. 6, Itala; Minoia the No. 7, Dietrich, and Charles Faroux, ex-trolley car motorman in Milwaukee, at present Parisian journalist, took the wheel of No. 8, Motobloc—it was his first appearance in a pure speed test. After Garcet had gone on the second of the Mors cars, Nazzaro raised the cheer of the day when he and his Fiat started on the run of three hundred odd miles at a terrific pace. Hautvast and his exceptionally long-stroke Bayard-Clement were looked upon by the French just as likely to win as the Italian favorite Nazzaro. Henry Fournier steered the Itala which had been tuned up to a slightly higher speed since the Dieppe race. Trucco, the Italian, took the last Dietrich, Landon the last Mors, and Wagner the French ex-Darracq champion had the third Fiat. America had her only representative in Elliot F. Shepard, driving No. 16 Bayard-Clement, which had been handed over to him but a couple of weeks before owing to an accident to Rigal. The American had the lightest car of the team and the heaviest mechanic, a man who on account of his enormous size and weight had naturally to be dubbed "Baby." Piacenza closed the march with the third of the patriotically-named Italas, and then the race was on in good earnest.

Less than half an hour after the start, Duray had roared by again on his Dietrich, the time which was hoisted up on the board a minute later being 24:55 1-5, which for the 32-mile course works out at the merest fraction under 80 miles an hour. Lancia got ahead of both Gauderman and Demogeot on the first round, scoring 24:16, or just over 80 miles an hour. Gabriel maintained his position behind the Fiat and had just roared by when Gauderman's failure to appear in position was explained by his arrival with the left front tire and rim missing. He stated that the rim, which was a new Vinet with some modification which had not been previously tested, had flown off on the straightaway. He was able to hold the car to the road, but had to retire immediately, for the fixed rim was flattened beyond repair. The accident caused comment, for it was feared that there was going to be a repetition of the Dieppe rim accidents,



The Big Official Score Board and the Crowd In Front of It.

Minoia Changes a Tire on His Dietrich.

against which, however, careful advance provision had been made.

It was probably owing to this fear of rim failure that numerous changes had been made since the Dieppe race. The Michelin people had slightly modified their rim by the addition of a raised section opposite the valve, and a special pin to prevent the single locking turnbuckle getting out of vertical. It proved successful, not a single accident or mishap occurring. The Dunlop rim found a place on the rear wheels of several of the cars, but no driver would accept it for the front, the opinion being that it was too heavy, and that its powerful lock threw the wheel out of balance sufficiently to interfere with the steadiness of the car at highest speeds.

Minoia furnished the highest rate of speed on the initial round, his Dietrich getting round in 24:15 2-5—over 80 miles an hour. Lancia came next, followed by Wagner, Gabriel, Duray and Elliot F. Shepard. Hautvast, the American's team mate, failed to make the initial round with No. 11 Bayarad-Clement. His own explanation was that the steel-studded tires refused to hold when he applied the brakes to make one of the right-angle turns. He skidded as if he were on soap, had to choose between the spectators and the ditch and went into the latter, his car broken, but without a scratch to himself or mechanic. Charles Faroux was unable to finish the initial round, one of the universals between the gearbox and the countershaft having developed weaknesses during the first ten miles.

Lancia jumped into second position during the second round, getting over the course in the record time of 23:24, or at the killing pace of 84.3. It delighted the spectators, nine-tenths of whom were Italians, and the sight was really terribly impressive, for the speed past the grandstand, on a perfect straightaway, with a very slight down grade, must have been close on 90 miles an hour. Wagner got second position, followed at three minutes by Henry Fournier, who had jumped in one round from ninth place. Nazzaro was maintaining a steady pace in fourth position, while Elliot F. Shepard was at the end of the list with Landon of the Mors team to keep him company in the same class.

Lancia Making a Replacement of Tires.

Henry Fournier made a fine struggle with Lancia during the third and fourth rounds. On passing the grandstand at the end of the second round the Italian had a lead on the Frenchman of a fraction over three minutes. By the end of the second round Lancia and his Fiat had increased the distance from the Itala by exactly one minute. Fournier, however, was hard after him, and by some of the most dashing driving ever seen got past the Fiat and won first place. His triumph, however, did not last long enough to be officially recorded, for on arriving at the last bend before the grandstand straightaway he went into the ditch but a yard from Hautvast's Bayard-Clement. Fournier was certainly going too fast; he failed to notice the slow sign until he was immediately under it, and was then handicapped by a cloud of dust raised by Cagno, who was just ahead. He thought he had got clear round, when the left rear wheel slipped off into the ditch, and it was all over. Fournier was slightly cut about the mouth and had bruises on various parts of the body; his mechanic escaped with just as little injury.

Duray on the Dietrich and Piacenza on the Itala had both failed to appear after the first round. The fate of the latter was not known until the end of the meet, when he drove in and explained that a disarrangement of the timing gears had obliged him to dismount the lower half of the crankcase.

The mystery about Duray was explained, just when Nazzaro had worked into first position, by the slow arrival of Wagner's Fiat with Duray and Mechanic hanging on behind. In the white jersey decorated with the Lorraine cross Duray had a portion of an exhaust valve which told the story of his undoing. One of the exhaust valves had broken, dropped into the cylinder and quickly done damage that was beyond a roadside repair. Wagner was also entirely out of the running, with a front axle that had broken exactly through the middle. It was an unusual mishap, that might have been due to crystallization or to an unusually severe shock when passing over a lump on the road, the car going up and dropping down on one wheel. The axle really looked as if it had been cut through with a hacksaw. Wagner made a temporary repair with a log of wood and a few lengths of rope.

Though seven cars had gone out during the first four rounds, there was no lack of interest at the tire and gasoline station, the course being but two miles round and therefore providing frequent passages. The killing pace was having its effect on tires, which were being changed by some of the drivers at the rate of almost one a round. When they were pulled off most of the tires were mere masses of pulp, so hot that they could not be touched, and smelling like a vulcanizing establishment.

At the end of the fifth round, while leading by less than two minutes on Trucco's Dietrich, Nazzaro pulled in at the grandstand, jacked up the rear of his car and changed both tires. This was the only work he did at the tire station, one other tire being changed on the road; the front tires went the whole distance. Smooth Michelins in conjunction with the new and modified rim were employed. On arrival at the grandstand a large sized bird was flattened out against the radiator of the Fiat, giving an indication of the speed at which the car had been traveling.

The struggle was now between Nazzaro, Trucco (Dietrich), Lancia, Garcet (Mors), all of them so well grouped that although Nazzaro was leading the final issue was doubtful. During the sixth round Lancia's ill-luck attacked him in the form of the breakage of an overhead rocker arm, the replacement of which at the central tire station occupied about twenty minutes and removed all possibility of first place.

During the sixth round of the leaders it was learned that both Landon (Mors) and Elliot F. Shepard (Bayard-Clément) had been put out of the game. The Mors driver failed to make one of the turns, shot off the road and landed in the canal containing 12 feet of water. Fortunately the men were not pinned underneath, and a few minutes later were on the road again. Consid-

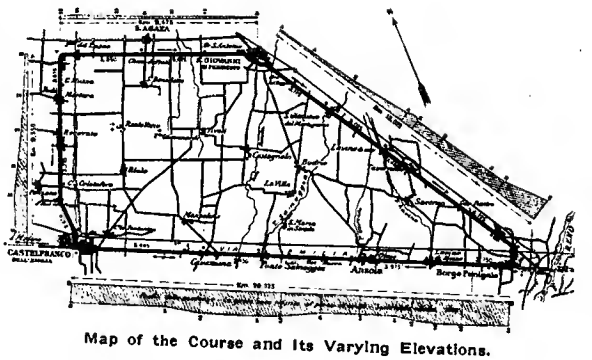
ering the fall, it was surprising how little damage had been done: one driving chain had been torn off, the hollow countershaft had snapped in two and the exhaust piping had been carried away. Every other part was intact. Elliot F. Shepard explained his accident when he drove into the paddock at the end of the fifth round. The left rear tire burst and locked the wheel with such violence that the rear axle casing made a half circle, the truss rod being broken off and brake connections snapped. Most of the bolts having been sheared, one-half the axle casing began to come away from the differential housing. Though it was possible to run the car, speed was out of the question. Shepard therefore remained in the paddock until the end of the race, then ran back to town, carrying his wife with him on the racer.

From seventeen the number of competitors had been diminished to eight: Nazzaro (Fiat), Trucco (Dietrich), Cagno (Itala), Minoia (Dietrich), Gabriel (Bayard-Clement), Demogeot and Garcet (Mors), and Lancia (Fiat). Trucco was running almost neck and neck with Nazzaro, Carcet might have been really dangerous had not a leak sprung up in his radiator system, obliging him to carry a jug of water with him; Demogeot and Minoia were gradually increasing their speed, while Gabriel and the powerful Bayard-Clement surprised and disappointed the French and their supporters by remaining in fifth and sixth position.

But it was not Gabriel's lot to finish, the overhead exhaust valve of the second cylinder breaking off and falling in, just as had happened to Duray's Dietrich. There were now seven struggling for victory, the two Dietrich's and the one Itala being so dangerous that they all beat Nazzaro on the eighth round. Lancia, too, was coming to the attack again, after his long delay, and seemed capable of gaining one or two places.

When the red No. 10 roared by on the last round, with victory certain for Nazzaro barring accidents, the cannon boomed and the grandstand got ready for a rousing reception. They were not disappointed, for 27 minutes later, with a margin of nine minutes in his favor, Nazzaro was the winner of the Florio cup, disputed for the third time. With one voice the grandstand roared: It was more than a national victory, it was the triumph of the favorite. Five minutes later the car had been run into the official garage, Nazzaro had spent half a minute in the ambulance tent to have the dust wiped out of his eyes and was being conducted across the road for the official presentation to the Princess Laetetia. This man, who had been driving at more than seventy miles an hour for over four hours, was as clean as on the morning he presented his dainty-looking car for the official inspection.

While Nazzaro had been making sure of first place there had been a keen struggle between Cagno (Itala) and Minoia (Dietrich) for third position, second place already being assured to Trucco. The Dietrich would certainly have got third in addition to second place, but for the collapse of one of the front wheel bearings, on a curve ten miles from the finishing point. This



Map of the Course and Its Varying Elevations.

gave Cagno his chance, and the Itala finished third, followed by Demogeot on the Mors at one minute's interval. Lancia came in fifth and Garcet on Mors sixth. Had the race been five miles longer, Demogeot would certainly have got third place, for the Itala which beat him had one of the rear dumb irons broken off, sending the axle adrift, and lost all its water after standing a few minutes in front of the station. The result of the race was thus as follows:

Fiat, Nazzaro	4.25.21	Average 74.3 miles
Dietrich, Trucco	4.34.7	Average 71.8 miles
Itala, Cagno	4.56.12	Average 66.4 miles
Mora, Demogeot	4.57.11	
Fiat, Lancia	5.08.51	Average 83.7 miles
Mora, Garcet	5.22.7	Average 61.1 miles

Though no troops were employed on the course, order was perfect with the exception of a slight incident at the end. After the arrival of the second car the crowd invaded the course and half a dozen cyclists—cycles are as common as macaroni in Bologne—mounted their machines for a quick run home. Duray, who had been a spectator since his accident, sent forth a war whoop, seized the first cyclist, knocked him to the ground and flung his machine into the Dietrich gasoline station. Somebody from the top of the tire stands flung down an empty wooden box on the heads of the invaders, the committeemen acted vigorously, for a racing car might have appeared at any moment, and in a few minutes the road was clear again. There was none of the grandstand decoration that characterized Dieppe, but there were few points of the organization which could be criticized. The tarring of the road was especially well done.

Contrary to what had been generally published, Nazzaro has no intention of abandoning the racing game at the end of the season. His marriage with a Turin lady is announced for next spring, but this will not cause him to abandon racing. Lancia, on the other hand, will cease to figure at the wheel of racing

Missed turn; went into ditch.
Broke universal joint on cardan shaft.

cars, his own private business having assumed such proportions that all his attention is required there. In the Savannah race it is almost certain that the Fiat team will be made up of Nazzaro, Wagner and Duray, the latter being at the end of his term with the Dietrich people and ready to sign with the Italian house. As the result of the Bologna defeat French representation will be small in the Savannah race. It is practically certain that Bayard-Clement will engage two cars and Dietrich either one or two. The others will not participate from the present indications, and there is little prospect of a change of policy.

PORPORATO SCORES VICTORY IN TARGA BOLOGNA

BOLOGNA, ITALY, Sept. 7.—Berliet, a French firm that has never previously attempted to win speed honors, but occupies, nevertheless, an enviable position in Europe, has won the Targa Bologna hands down. Porporato, the Italian driver of the winning car, covered the 262.5 miles in 4:0:56, which is equal to 65.3 miles an hour—very satisfactory going for a four-cylinder car of but 120 millimeters (4.7 inches) bore. True to their fixed policy, the Lyons factory refused to enter a car in the Italian race, but gave permission to Porporato, one of their chief testers,

Porporato in His Berliet Winning the Targa Bologna.

to make any changes he liked on the standard model and race it on its own responsibility. Under the rules 130 millimeters is allowed all four-cylinder cars; the Berliet model measures 10 millimeters short of this, and it was with this handicap that Porporato set out to prepare for the race. He and his mechanic worked single-handed, the firm being so little interested in the race that not a single official from the factory was present when the call came for the designer of the racer to be presented to Princess Letizia.

The story of how the race was won is easily told. There were sixteen starters, thirteen of them being Italian and three French. Franchini, on a Bianchi, set the pace with an initial round covered at the rate of 73 miles an hour. Porporato was content with fifth position. The first round saw the Fiat and a Junior go out of business; then failures came so thick and fast that by the end of four rounds nine cars had disappeared through mechanical defects or road accidents, among the breakdowns being Vincenzo Florio's Darracq and the French Dietrich.

During this time Porporato and his Berliet had been reeling off rounds in 28, 29 and 30 minutes, working up to first position during the fourth round. During the fifth he stopped to replace a smooth Dunlop rear tire by a non-skid and to add a pint of water to the radiator, done without a stoppage of the engine. Later a rear tire ended its life with a loud report, the strain of a curve at 50 miles an hour having been too much for it. These were the only two occasions on which Porporato left his seat; from beginning to end the bonnet was never raised. Taking advantage of the rule which allowed the changing of wheels during the race, Porporato carried two spare front wheels, with inflated tires in position, on his rear brackets. They remained there, however, until the end of the race, for no tire trouble developed in front. Porporato declared that his reason for taking complete wheels in preference to rims was that the former could be changed quicker than the latter. The car being chain driven it was impossible, owing to weight, to set in the same way with the rear wheels.

A feature of the race was the absence of tire trouble. Although the speed attained was frequently 80 miles an hour, as is evident by the winner's average of 65, there was so little attention needed to pneumatics that for the first hour and a half not a single tire had been changed at the grandstand depot. On the previous day, when the winner's average was only nine miles an hour more, tire trouble was prevalent, showing that the 155 millimeter international rule has produced a car so fast that it is constantly in danger of failure by overstepping the limits of tire resistance. The lesson that has been forced home is that a bore of 130 millimeters is all that is required for the most powerful racers; beyond this speed is so great that there is a constant danger of mechanical lessons being lost owing to the failure of tires to support the strain. Doubtless the lessons of this season's racing will have the effect of deciding the international association to further reduce the maximum bore for racing cars.

Second place in the race fell to an S. P. A., handled by Appendino, who made a very slow initial round, but who immediately after jumped to the front and trailed Porporato for the last four rounds. Third place went to Buzio, on a Franco, another Italian combination. After being third and fourth for a long time, the Franco was obliged to dismount a portion of its carbureter, an operation that occupied nearly half an hour, despite the aid of a group of mechanics, and destroyed all hopes of a better position. Tangazzi's Junior went into fourth position; Maggioni's Zust got fifth place, and Piccoli's S. P. A. finished sixth. The rest abandoned before the eighth round had been accomplished.

As the result of the remarkably easy victory of the Berliet it is very probable that the firm will be represented in the next Grand Prix of the Automobile Club of France, more especially if, as is considered almost certain, the club decides to limit bore still further.

RESULT OF THE RACE FOR THE TARGA BOLOGNA—DISTANCE; 262.58 MILES.

USEFUL THINGS FOR THE AUTOIST TO KNOW

SECOND-HAND cars at a close figure are apt to have tires barely up to requirements of the tire manufacturers' guarantee. Such tires suffer from rim cuts and blow outs much more than tires a trifle larger, since the small tires have to be pumped quite hard, and even then flatten more under load than larger tires under like conditions. In purchasing a second-hand car it is well to consider the matter of tires somewhat carefully, and to figure on substituting larger tires if those used are under suspicion. A safe rule is to have the tires 1-2-inch in section for each 100 pounds of total load, including passengers and supplies. For example, a 3 1-2-inch tire should not carry over 700 pounds maximum. The tire makers have brought out two odd sizes of tires especially to take the place of smaller sizes without change of rim. These are the 31 by 4 and the 33 by 4-inch sizes. The 31 by 4 size will go on a 30 by 3 1-2-inch rim, and the 33 by 4 on a 32 by 3 1-2-inch rim, without changing the rim. Occasionally one finds a 34 by 3 1-2-inch tire which is too heavily loaded. Here one's best hope is that the felloe can be cut down for a 34 by 4-inch rim without seriously weakening it.

Looking Over the Lubrication Heads.

The oil and grease cups on joints of the steering gear, springs and other small bearings scattered about the car easily become clogged. It is not sufficient to see that the oil cup is filled with oil or that the grease cup is screwed down as far as it will go. Unless the oil actually runs in and the grease cup is observed to be slack after running, it is clear that the bearing is not receiving lubricant, and the best thing to do is either to force kerosene in, or, better, to take the bearings apart if possible, and clean out the solid particles with which the oil passages are probably clogged. Pour kerosene through the "breathers" in the crankcase up to the normal level of the oil. Start the engine and run it two or three minutes, thereby splashing the kerosene thoroughly about the crankcase and valve mechanism. Stop the engine and draw off the kerosene, which will carry with it a considerable accumulation of dirt and metal dust from the bearings. Refill the crankcase with clean oil and run the engine again—without load—for a few minutes to insure that the oil is splashed to all bearings needing it. It is now safe to run the engine under load.

Oils for Gearbox and Rear Axle.

If the gearbox and rear axle have plain bearings, the oil must be considerably thinner than if ball bearings are employed. The reason for this is two-fold. A fluid oil allows the grit from the gears a chance to settle, and it enters the bearings more freely than a semi-solid lubricant would. For plain bearings, regular gear case oil is about right in warm weather, especially as it is thinned somewhat by the warmth received from the engine and exhaust pipe. In cold weather it may be necessary to thin the oil with kerosene to induce it to flow at all. If, however, ball bearings are used, or if the bearings are plain but are separately lubricated, including the telescope bearing at the end of the sliding gearshaft, it will be safe to add a double handful or so of grease to the gearcase oil, leaving it just soft enough to flow slightly when warm.

Possible Carbureter Trouble.

In case the motor fails to start readily on priming the carbureter, and the mixture is found to be over rich, it may be that the drainage hole in the carbureter is clogged so that the overflowing gasoline accumulates and makes too rich a mixture. This, of course, does not apply to carbureters in which the overflow of gasoline dries out on the ground without depending on a drainage outlet.

Safe and Unsafe Dust Pans.

Drain outlets should always be provided at the lowest point of the dust pan and at the bottom of any "pockets" it may contain. If this is done, gasoline accidentally finding its way into a pocket will not remain, and there will be no danger of its catching fire, something that is always imminent with collected gasoline.

USE OF TIRE CHAINS IN PARKS DECLARED LEGAL

THE American Automobile Association and the National Association of Automobile Manufacturers have won out in their fight against the constitutionality of the notorious ordinance of the New York Park Board, prohibiting the use of tire chains on park roads. Justice Davis has decided the ordinance to be illegal, unconstitutional and void.

The test case was conducted for the two associations by Charles Thaddeus Terry, chairman of the legislative board of the A. A. A. and counsel to the N. A. A. M., through a writ of habeas corpus in the case of a taxicab driver.

The ordinance was declared invalid by Judge Davis upon the following grounds:

FIRST: That it was in direct violation of the motor vehicle law of the State of New York, known as Chapter 538 of the Laws of 1904. Upon this point the court said:

"This statute contains a uniform and comprehensive plan for the regulation of the use of highways by automobiles, except in respect to speed, and forbids the adoption by local authorities of ordinances regulating that subject.

"The ordinance in question contrary to this statute excludes from the free use of the park highways all automobiles having chains on their wheels, even though they have complied with all the provisions of the motor vehicle law, and admits them to such free use only upon getting permission from the commissioner. For this reason the ordinance cannot be upheld.

"We may assume that the purpose of the rule is to protect the roadbed, although that does not appear from the record, but whatever its purpose may be, the effect is to regulate the use of automobiles whose owners make use of chains to insure their practical and safe operation over the highways of the parks when they are muddy, slimy, or otherwise slippery. As stated above, such regulation by the local authorities is forbidden by the statute referred to."

The court distinctly lays down the rule in its opinion that the State motor vehicle law is absolutely comprehensive upon the questions of the regulation of motor vehicles, and that it forbids all regulation of such by local authorities with the one exception of speed, and this only when the conditions prescribed by statute are complied with.

SECOND: Upon the question of the unconstitutionality of the ordinance, Judge Davis held that in conferring an arbitrary power upon the commissioners to discriminate between those to whom they shall grant permits and to whom they shall be denied, the ordinance denies the equal protection of the laws and is in violation of the Constitution of the United States and of the State of New York. The court said:

"It is a vital defect in the ordinance that it contains no provision guaranteeing uniformity in its enforcement. No rule or principle is provided to secure its impartial execution. Inequality in its enforcement is thus not only possible, but probable, and so it fails to insure equal protection to all persons similarly situated and for this reason it is unconstitutional."

The court further held that the ordinance was in violation of the Constitution of the State of New York and of the 14th Amendment of the United States Constitution in that it arbitrarily discriminates between chains and other devices used to prevent skidding of automobiles. Upon this point the court said:

"Why the owners of the chain device should be put in one class and those using the other devices in another and exempt class, is not at all clear. . . . Indeed one fails to discover any reasonable basis or principle whatever, justifying the placing of the chain method in a prohibited class by itself. It follows, therefore, that the ordinances make an unlawful discrimination against those who use chains as a part of their vehicle equipment."

This decision of the Supreme Court effectually establishes what has always been the contention on the part of the automobilists of this State.

THE STATUS IN AUTOMOBILE RACING.

Automobile racing, at least for the moment, is of some substantial worth to automobiling in general. Therefore, it will be a source of general satisfaction to those manufacturers and their agents, who bear the brunt of the heavy expense, that an agreement has been reached in the so-called racing war between the American Automobile Association and the Automobile Club of America. The exact interpretation of the agreement signed by the officers of the two organizations may safely be left to the lawyers who were involved in the final understanding. It would appear that whatever friction may be engendered for a time by those interested in preventing harmony, will soon give way to the insistence of the common-sense of the men really responsible for the recently reached understanding.

The need for an organization like the American Automobile Association is absolute and recognized, whether it be composed of clubs, or individuals, or both. The big club in New York City also has its sphere of usefulness, and being located in the metropolis of the country, it possesses certain advantages over the clubs of other cities. The constitution of the international organization provides for only one club from a country, and the A. C. A. unquestionably was in on the ground floor in the pioneer days of automobiling, and that was how it obtained its "foreign recognition," which it values highly and which it has fought to preserve, and has succeeded in preserving. But the A. C. A. was unsuccessful in inducing the clubs of this country to desert the A. A. A. and acknowledge the New York City organization as the fountain head of national power. Therein it encountered defeat, for the American spirit of the American clubs will not accept the foreign idea of the autocracy of a single club in a country.

The great thing, however, is that both the Vanderbilt and Savannah races will now be successes—one is needed in the metropolitan district, and the other will be of benefit to the sport and industry in the South. The mere fact that the Vanderbilt race is called "national," though its entry list will be "international" in character, doesn't retract one whit from its prestige, nor its value, to whatever maker may be lucky enough to be first across the line. A generous entry is promised in both events, though had the "war" continued it would have meant competition of slight worth to those participating.

Therefore, let us concern ourselves with the two big races scheduled, and let the future more or less work out its own problems, for ultimately it will resolve itself into a question of what the manufacturers of America shall decide to support and how they shall support it.

* * *

GROWTH AND INFLUENCE OF THE S. A. E.

The many and varied phases that engineering endeavor naturally assumes, and the fact that while the engineer keeps track, in a general way, of the inventions and progress of lines other than his own, he is only vitally interested in the particular branch in which he is occupied, makes necessary the devotion of a separate engineering organization to each field. In order to achieve that degree of cooperation in the study of a number of problems that is necessary to their most practical and enduring solution, it is evident that all must be working toward a common end, and it was on this account that membership in some of the older societies proved of little, or no help, to the automobile engineer in his early struggles. Hence, the conception of the Society of Automobile Engineers, which held its third quarterly meeting for the present year in Cleveland last week.

The S. A. E., as it has now come to be known familiarly, first came into existence in the Summer of 1905, and like other movements of a similar nature, it suffered in its early days from a lack of attention on the part of its promoters, who found themselves, in the main, far too busy building cars or manufacturing parts to find much opportunity to devote to a study of how those things could be done to better advantage outside of the walls of their own shops. But the demand for cooperation and investigation, which had already been recognized by the manufacturers' association, was felt more than ever by those outside the latter, and the Society of Automobile Engineers not only continued to exist, but to slowly gain recruits in spite of the fact that its light was hidden most of the time. Since 1905, when it was created with a charter membership of less than 50, it has steadily continued to expand, and its growth during the present year has been such that it now numbers more than 200 members, among whose ranks are to be found many prominent designers and accessory makers.

VANDERBILT AND GRAND PRIZE OPEN TO ALL

A STOP has been put by the parties themselves to the so-called "racing war" between the American Automobile Association and the Automobile Club of America. The conference committees, which were in executive session for a fortnight, with the chief idea of making an adjustment of differences between the two bodies over the running of the Vanderbilt Cup race on Long Island and the Grand Prize contest at Savannah, concluded their negotiations last week and received the approval of their respective principals to the compromise agreed upon.

Following the endorsement and signing of the document, the following official statement was issued simultaneously by both bodies on Thursday:

IT IS AGREED that the Automobile Club of America is the only American member of the International Association of Recognized Automobile Clubs, and that it is and shall be the only authority in America for the drafting of rulee affecting and for the granting of sanctione for international races, and for the regulation of such races in this country. On the other hand, the matter of the sanction of and the formulation of rules for local and national races is agreed to be, as heretofore, in the sole power and jurisdiction of the association. The two bodies agree to cooperate with each other in making the Vanderbilt Cup race and the Savannah Grand Prize race successes. After the races of this year the two cups are to be deeded to an independent racing association, and are to be contested for annually, the Grand Prize Cup as the International trophy and the Vanderbilt Cup as the National trophy. It is also agreed that the club shall not encourage other clubs to withdraw from the American Automobile Association.

The essential pointe at issue between the two organizatione have thus been settled, and their cooperation in the future in all matters relating to the sport of automobile racing is aesured.

The full text of the agreement was made public by the club on Tuesday. It disclosed other concessions and pledges not embraced in the official statement at first issued. They embrace:

A definition of "national" and "international" racing in this country.

An agreement on the part of both bodies to hand over next year the Vanderbilt Cup and the Grand Prize to a corporation controlled by the Long Island Motor Parkway, Inc., on condition that it promote "national" and "international" races respectively for the two trophies.

The appointment of the Automobile Club of America as the sole representative of the American Automobile Association in foreign racing.

An agreement on the part of the Automobile Club of America to retire from the promotion of automobile racing after the running of the Grand Prize at Savannah.

A provision that the present "peace agreement" may be terminated upon the first day of January in any year after January 1, 1910, upon twelve months' previous notice in writing.

Pending a thorough understanding regarding the various clauses of the agreement, a joint committee from the A. A. A. and the A. C. A. will pass upon any differences that may arise in the premises.

The text of the agreement as given out by the club follows:

This agreement made this 11th day of September, 1908, by and between the Automobile Club of America, a membership corporation, created under the laws of New York, and the American Automobile Aseociation, a corporation created under the laws of New Jersey, witnesseth:

I. That the American Automobile Association recognizee and acknowledges the Automobile Club of America to be the sole American representative and member of the International Association of Recognized Automobile Clubs, and that as such it is and shall be acknowledged and recognized as the sole and unqualified authority for all international automobile affairs, including races and contests, in the United States of America.

An international race or contest is one which is announced or advertised as "International," or one which is open to entrants of America and foreign countries. Cars of foreign manufacture may be entered in a race or contest without making the same as "International" race or contest, provided, however, that such cars be owned and ENTERED BY AMERICAN CITIZENS, FIRMS, OR CORPORATIONS.

II. The Automobile Club of America agrees that after it has conducted the Grand Prize Race at Savannah, in November, 1908, it will RETIRE from the promotion of races, so long as International racing shall be conducted in the United States of America under the SANCTION of said club and in accordance with the RULES of the International Association of Recognized Automobile Clube, in as far as such rules ehall apply to the race in question.

III. The American Automobile Association agrees to have changed the conditions of the VANDERBILT CUP race, proposed to be held on Long Island, in the Fall of 1908, so that the same shall be a purely NATIONAL race and not International in character, and in that event the Automobile Club of America agreee to REMOVE ALL EMBARGOES and disqualificatione on such Vanderbilt Cup race, and the same shall be raced under the rules and conditions as now announced, except such conditions as would make it an International race, and the Automobile Club of America agrees to do everything in its power under these conditions to make such race a success.

IV. The American Automobile Association agrees that it will do everything in its power to make the GRAND PRIZE race at Savannah, proposed to be held in November, 1908, a success and to REMOVE ALL EMBARGOES and disqualifications against said race and to use its influence in having as many American cars ae possible to enter this international race.

V. That after the year 1908 the Automobile Club of America agrees to TRANSFER, under a proper deed of gift, its gold GRAND PRIZE cup to a corporation controlled by the Long Island Motor Parkway, Incorporated, upon the condition that the said donee each year promote and conduct an international race for the same, under the sanction of the Automobile Club of America and under rules then existing of the International Association of Recognized Automobile Clube.

VI. The American Automobile Aesociation agreee that after the year 1908 it will have TRANSFERRED to a corporation controlled by the Long Island Motor Parkway, Incorporated, the VANDERBILT CUP, upon the condition that the said donee will promote each year a national race for the said cup, under the sanction and rules of the American Automobile Association for national races.

VII. The Automobile Club of America agreee to make no attempts to encourage other clubs to withdraw from the American Automobile Aesociation.

VIII. It is hereby mutually agreed that the Automobile Club of America shall be the sole representative for the American Automobile Association for all foreign countries.

IX. Thie agreement shall be binding on both parties hereto until terminated, as hereinafter provided. It may be terminated upon the first day of January in any year after January 1, 1910, upon twelve months' previous notice in writing.

In witness whereof the high contracting parties have caused these presents to be signed by their duly authorized officers, the date first above written.

FOR THE AUTOMOBILE CLUB OF AMERICA,
(Signed) HENRY SANDERSON,
First Vice-President.
S. M. BUTLER,
Secretary.

FOR THE AMERICAN AUTOMOBILE ASSOCIATION,
(Signed) ROBERT F. HOOPER,
FREDERICK H. ELLIOTT,
Secretary.

How Foreign Cars May Enter Vanderbilt.

The status of foreign-made cars in the Vanderbilt Cup race is explained by Jefferson de Mont Thompson, chairman of the Cup Commission, to be as follows:

In view of the fact that the race for the selection of the American team has been cancelled and under the deed of gift a team of ten cars could compete in this race, the commission deeires to call the attention of American citizens owning foreign-made care, and American agents, whether firms or corporations, representing foreign-made cars, to the fact that care of foreign makes, irrespective of selling price, cylinder capacity, or other restrictions, save for in weight, are now eligible for competition in the Vanderbilt Cup race.

Arrangemente providing for a change in the character of the competition for this cup contemplate a change in the deed of gift, and the deed of gift has been changed by the donor, Wm. K. Vanderbilt, Jr., at the request of the Association.

The conditions provide simply for a classification by weight with a maximum limit of 2,644.8 pounds. The commission has also extended the date of entry without penalization, to October 1, and the entry fee of $1,000 will entitle a manufacturer to enter one, two, or three cars.

VANDERBILT AND GRAND PRIZE ENTRIES.

Two more entries added to the list of Vanderbilt Cup candidates quickly followed the announcement of the end of the "racing war." Clifford V. Brokaw has furnished an Italian contender by nominating an Isotta. The American entrants have been increased by the naming of a Matheson by the Matheson Motor Car Company, of Wilkes-Barre, Pa. This new aspirant for cup honors is not the Matheson that competed in the last race on Long Island, but a new car entirely with 6.1-inch cylinders. With Robert Graves' Mercedes, and a Thomas, a Mora, an Acme, a Chadwick and the two Knoxes, the list of entries already made

now reaches nine. The two Locomobiles promised practically raise the list to eleven. Entries will close on October 1.

Since the entry blanks and formal announcements have been issued, the engineers of the Parkway have reported that the work of construction is practically completed. The largest bridge on the parkway, which is at Central Park, was turned over to the cement workers last week. This bridge connects two long sections of the cement highway between Central Park and Bethpage, the Central Park and the grandstand.

All of the grandstand stretch is completed and cars have been running over it for some days. There is a little more work to be done between the grandstand and the western end of the parkway, but the bridges over intersecting highways in this section are open and the finishing touches can be put on in two or three days. This practically completes the eleven miles of parkway which forms a southern boundary of the 1908 Vanderbilt Cup circuit. The grandstand is about half completed. The telephone service has been installed around the entire circuit, and racing drivers who have been selected by the various entrants are preparing to open their headquarters on the parkway about the first of the month.

Fred J. Wagner, who is looking after entries for the Parkway Inaugural Sweepstakes, reports unbounded interest and enthusiasm in the trade over the novel event and is confident that at least 20 starters will await the word "go" on October 10. The division of the entrants into "thousand dollar" selling classes, the scaling of the entrance fees on the basis of price, the different distances to be run by each price class, and the fact that the entire field will race on the course together are proving popular with the makers and dealers, while the magnitude of the contest is arousing general public interest.

Entries for the Grand Prix at Savannah are at present set to close on the same day with the Vanderbilt nominations. The A. C. A. has a noteworthy international nucleus in the entries already made of three Fiat and three Benz cars. The Vanderbilt Acme was nominated this week and the entry of the Vanderbilt Matheson and of Mr. Buckley's B. L. M. racer also reported. A considerable foreign entry is already practically assured and a generous American participation probable.

The club has chartered the *City of Savannah* for its members. It will sail the Saturday before and return the following Saturday. There will be room for thirty touring cars aboard. The club is also arranging for special Pullman trains to leave Monday and return on Friday. Passengers on the steamer and trains will sleep aboard during their stay in Savannah.

NAZZARO WILL RACE AND MARRY LATER.

BOLOGNA, ITALY, Sept. 15.—There is no truth whatever in the announcement made about a month ago that Nazzaro would retire from the racing game this season. The marriage of the clever but modest Italian driver is fixed for the beginning of next year, but this will not interfere with his racing contract with the Fiat firm. It is now certain that Nazzaro and Wagner will be sent over to handle the Fiats engaged in the Savannah race on Thanksgiving Day. Lancia declares that he will not be at the wheel of the third car, his own business engagements in connection with the Lancia car making it impossible for him to travel to America. Though no official decision has been arrived at yet, it is exceedingly probable that Duray will have the third car. The Belgian driver is still connected with the Dietrich firm, but as his contract expires very shortly it is believed that he will be able to handle Lancia's car.

French participation in the Savannah race is not likely to be great. Dietrich may send two cars, and Bayard-Clément may be represented by Gabriel and one other. As to the rest, it is practically certain that they will remain at home. Demogeot is looked upon as a likely driver of one of the Dietrichs.

Ironton, O.—An automobile line between this city and Proctorville is now practically assured. A 20-passenger car will be used and two round trips will be made daily.

QUAKERTOWN'S STOCK CHASSIS RACE.

PHILADELPHIA, Sept. 21.—Five bona fide entries have already been secured for the 200-mile Founder's Week stock chassis road race, with excellent prospects of the limit of 20 entries, set by the committee being reached before October 7, the date of closing. The quintet already entered are: Maxwell, entered by the Tarrytown factory; American Locomotive, entered by Louis J. Bergdoll (who will also drive the car); Stoddard-Dayton, entered by the Hamilton Auto Company, Philadelphia agents; Peerless, entered by P. F. du Pont, of Merion, Pa., and Studebaker, entered by the factory and to be driven by Frank Yerger. Two Loziers, two Locomobiles, a Pullman, another Studebaker, a Pennsylvania, a Stearns, a Matheson, and a Renault are almost sure to be among the starters.

Contracts for the building of the grandstands and official stands have already been entered into; they will be located on the South Concourse, almost opposite Memorial hall.

The committee has decided to make the race 195 miles—25 times around the 7.8 mile course—and the knowing ones say that barring an epidemic of tire troubles, more than one can and will approach the mile-a-minute average. The only bad points on the course are the Sweet Briar hill and the swing into the Neill Drive from the West River Drive under a rather narrow railroad bridge. All the other turns are wide and gradual.

No road race was ever run off in this country over a course within 20 minutes' street car ride of a million and a quarter people, and for this reason the committee has decided to rope and fence off the entire course on both sides, in addition to using the 1,500 or 2,000 guards to be supplied by the city.

ANOTHER 24-HOUR AT BRIGHTON BEACH.

As was anticipated would be done, the Motor Racing Association has decided to run another 24-hour race at Brighton Beach, N. Y. It has set the dates for Friday and Saturady, October 2 and 3. At the meeting at which the decision was reached, pledges of 10 entries were received from members for the big race. Harry Lozier agreed to nominate the four-cylinder Lozier, which finished second in the last race, and Harry S. Houpt announced that he would substitute a Thomas Flyer for the Thomas Forty that was given a demonstration run in the first race.

Negotiations are in progress to secure Oldfield and Christie for one of their match races. A four-cornered six-cylinder match race with a Lozier, a Stearns, a Thomas, and an Acme as contenders, and a special contest with Oldfield, Christie, the B. L. M., the Fiat Cyclone, and the Fiat Tornado as contestants, are in contemplation as special features for Friday afternoon.

Improved camp arrangements, restaurant service, and track lighting are promised. The association received a sanction from the Automobile Club of America for the meet as an "international event." The association has also approved the Motor Parkway sweepstakes.

STRANG ENGAGED TO DRIVE RENAULTS.

Announcement is made by Paul Lacroix, manager of the American branch of Renault Frères, that he has signed Lewis Strang to drive Renault cars in future speed events. Every opportunity will be given Strang to drive in all the races of any importance in this country, and besides the racing cars which this company now has in America the arrival of one of the Grand Prix racers is expected soon for entry in the races at Savannah on Thanksgiving Day. A Vanderbilt Renault is a probability.

RYUS IN WHITE WINS LOS ANGELES RACE.

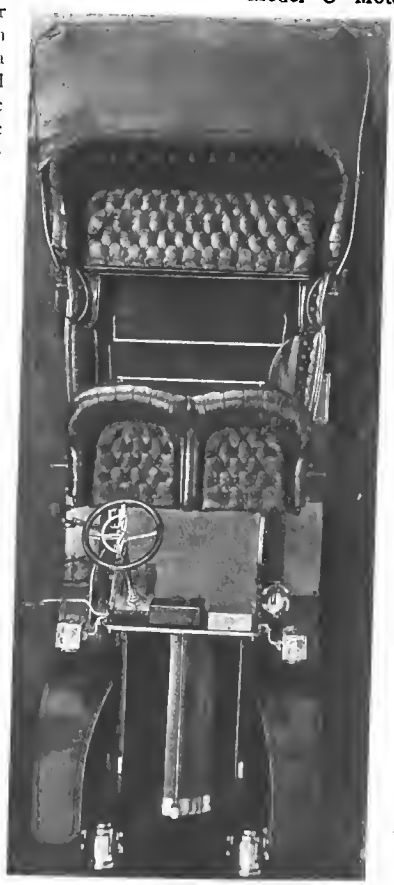
LOS ANGELES, CAL., Sept. 20.—The third annual 100-mile road race was run here to-day. A White steamer, piloted by H. D. Ryus, evolved as the winner. His time was 4 hours 34 minutes. Bert Latham, in a Kisselkar, was second in 4 hours 13 minutes. This is the third successive victory for Ryus and the White. Their time last year was 4 hours 30 minutes.

Knox 1909 Models

The 1909 Knox Model M from Springfield, Mass.—A Full-sized Touring Car of 50-horsepower Rating.

THERE will be three Knoxes for 1909, two water-cooled models and one air-cooled—the latter being for those preferring this type of motor construction. The following description applies to water-cooled types only, which are known respectively as models O and M. Model O is a 38-horsepower shaft-driven car, with motor, clutch and change-gear a unit construction, carried on a three-point support; whereas Model M, a 50-horsepower car, uses separate motor and transmission units, but carries each on a three-point suspension, it being also a chain-driven machine. Both models O and M will carry 1909 improvements in the matter of a three-disk clutch, replacing the cone type heretofore employed, and a modification of the intake and exhaust, as well as the intake and return water pipes of the motor. The changes in this piping greatly simplify the work of taking off the cylinder head, this being a separate part of the cylinder casting in Knox construction. Loosening the nuts retaining two yokes and taking off the nuts on the four studs holding the cylinder head in place, permits its removal for valve grinding or replacing.

Cylinder Construction.—The Knox cylinder design, having intake and exhaust valves in the cylinder heads and using a separate casting for the cylinder head, in order to waterjacket it more properly, results in a construction unique in American motor cars. The cylinder casting proper, with its integral waterjacket, has in its upper face a deep groove machined concentrically with the bore, into which fits a copper asbestos gasket; and in the cylinder head face is machined a circular tongue, which fits into the groove above the gasket. Four vertical bolts, which pass direct through the head, hold the two parts together. The water circulation, which enters the cylinder jacket at the bottom, is continued to the jacketing of the head through a short tubular connecting link in the form of a bridge casting, and the return flow is from the jacket part of the head to the radiator top. The inside of the cylinder head is also machined, so that the entire surface of the combustion chamber is smooth, and the capacity of the combustion chambers of the four cylinders as accurate as is obtainable. The maker claims that the smooth surface is less likely to retain deposits of carbon, and its freedom from short points or rough edges should eliminate preignition troubles from this cause also.



Knox Model O Seen from Above.

Model O Motor.—In this model the company continues the use of a unit power plant and three-point suspension, which is secured as follows. The upper half of the crankcase is formed with rearwardly extending arms, which encircle the flywheel and have their ends united by an integral transverse part, to which the front end of the transmission bolts, thereby uniting in one, for support purposes, the motor, clutch and gearset. This unit has its three-point support by a trunnion at the forward end, supported on a channel cross member, the ends of which rest on the frame pieces. The two rear supports are direct on brackets on the side members of the frame, lowered in order to secure a straight line drive from the crankshaft to the rear axle. According to A. L. A. M. rating, the model O motor is 38 horsepower, its cylinders having a bore of 4⅞ inches and 4¾-inch stroke. The intake and exhaust manifolds and the battery plugs are on the left, and the intake and return water piping, together with the short bridge pipes between the cylinders and the heads, on the right side. On this side also are located the high-tension magneto, toward the front, and the three-part group of oiler, timer and water pump at the rear. Intake and exhaust valves are made with integral head and stem and have the stems lubricated by carrying them through a gland. The usual rocker arm construction over the cylinder head is employed for opening the valves. Making the exhaust manifold in four parts allows for taking up of expansion through heating without transmitting any of this strain to the cylinders, and this manifold, as well as the intake, is securely anchored by four T-yokes.

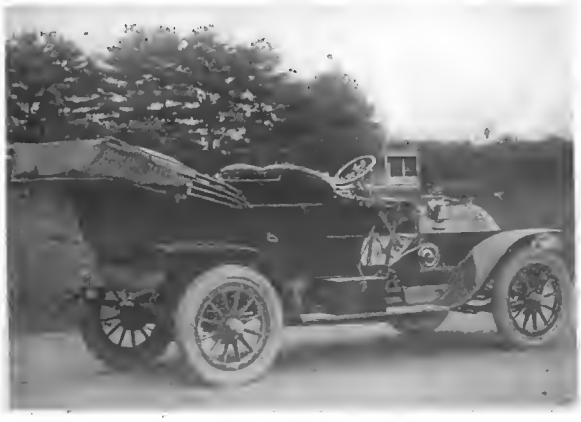
Gears and Gear-shafts of Model O, Dismounted.

Motor Accessories.—The oiling system is a positive feed, without the usual splash in the crankcase. At the right rear of the motor, and carried outside of the crankcase, is a gear oil pump driven by vertical shaft from the camshaft, which draws oil from the lower portion of the crankcase and forces it into a horizontal duct drilled in the upper half of the crankcase. From this are five branches to the five bearings of the crankshaft. Drilling the crankshaft in the usual manner conveys the oil to the lower bearings of the connecting rods, and drilling the connecting rods to the upper ends allows of forcing the oil to the wristpins, thus insuring a positive lubrication to the thirteen motor bearings.

The double ignition system consists of a gear-driven high-tension magneto, with wires direct to the plugs carried on that side of the motor, and a supplementary battery, Connecticut coil and timer, the latter on a short vertical shaft driven from the camshaft. The battery spark plugs are on the left side.

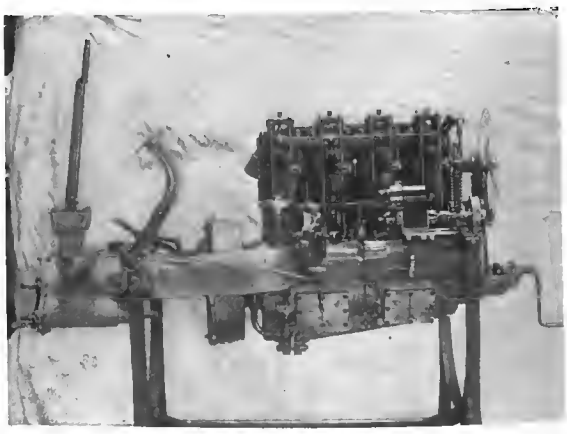
After considerable experimenting the company adopted the Stromberg carbureter, which is characterized by the transparent float chamber, spring controlled auxiliary air valve and water-jacketed mixing chamber. In the cooling system the pump maintains its unique position at the right rear, where it is driven by spiral gear from the timer shaft. It delivers the water through a tapered manifold to the base of the water jackets.

Transmission Improvement.—Carried within a recess in the flywheel is the new three-disc clutch, used for the first time, and which operates in oil. The middle disc contains cork inserts and connects with the transmission through its shaft; whereas the two outside discs attach to the flywheel. In the model O car the three-speed selective gearset is employed. Both shafts are carried on ball bearings, with a double ball race at the end of each shaft, one acting as a thrust bearing and one a radial bearing. In this model, as previously stated, the gearbox and cover are bolted to the rear end of the engine bed and are removable by withdrawing the connecting bolts; but, in addition to this, the gears and shafts may be removed without disturbing the gearbox or any other part of the power plant. The gearbox casting carries an extension enclosing the shifting rods for the speed changes.



The 38-Horsepower Knox Model O Touring Car.

Running Gear.—This model has a tubular front axle, with tierod located in rear of it; the steering knuckles are forgings, with heavy yokes. Hyatt roller bearings are employed in the rear axle, with ball races for taking the end thrust and two annular bearings for supporting the pinion shaft at the rear end of the propeller shaft. The steering gear is of the screw and nut type, the screw formed integral with the column and cut from a solid bar. Both sets of brakes are carried on the rear wheels, the emergencies expanding and the foot set contracting. Asbestos fibre is the friction material. Semi-elliptic springs are used throughout, the rear set being shackled at both ends. In connection with this double shackling is the employment of radius rods and the elimination of the torsion rod, the car being driven through the radius rods only. Thirty-four by 4-in. tires are used, the wheelbase measures 114 inches, and the weight approximates 2,850 pounds with equipment and five-passenger body. Model O is made in touring car, limousine, baby tonneau and sportabout.



Model O Power Plant, with Magneto, Pump and Timer.

The Model M Car.—The Model M car, with seven-passenger capacity, has a 50-horsepower motor, with 5¾-inch bore and 5½-inch stroke. Attention has already been invited to its one-piece crankcase. It employs the three-disk clutch, but uses a Mercedes type selective transmission, with four forward variations, and employs side chain drive. In other respects it is, except for size, a counterpart of the model O car. In touring car lines its wheelbase measures 127 inches, and the tires are 36 by 4½ and 5 inch. Like the model O car, it is manufactured in limousine and sportabout styles as well as touring car, and landaulette.

THIRD DIVIDEND IN POPE RECEIVERSHIP.

HARTFORD, CONN., Sept. 21.—Vice-Chancellor Howell, of Newark, to-day signed an order directing the receivers of the Pope Manufacturing Company to take such steps as may be necessary to secure the transfer of sufficient funds for the payment of a third dividend of 25 per cent. on the approved claims. There was pending an order obtained by Percy S. Bryant, of Hartford, as counsel for a creditor's committee representing claims originally in excess of one million dollars, directing the receivers to show cause to-day why they should not be compelled to pay a third dividend. Vice-Chancellor Howell also signed an order barring certain creditors from appealing from the decision disallowing their respective claims. The order was made pursuant to an order signed July 28, limiting the time of appeal.

LEGISLATION THE WAR CRY OF THE CLUBS

PENNSYLVANIA CLUBS CONSIDER NEW LAWS.

PHILADELPHIA, Sept. 21.—President Joseph H. Weeks, of the Automobile Association of Delaware County, Pa., has prepared three new laws which will be presented to the legislature when the next session convenes in January, 1909. The first provides for the appointment by the governor of a highway commission of three, who shall determine the location of the State's highways and pass upon all applications for State roads and in the building of roads. This measure also provides that where main highways of either telford or macadam are built by the State, a preservative binder shall be incorporated in the top layer of stone to prevent the blowing away of the roads in dust almost as soon as they are built.

Mr. Week's second bill proposes that the State shall build and maintain all main highways, and aid townships in constructing and caring for local roads; and his third measure provides that all money received by the State from automobile licenses shall be used for placing preservative substances on State-aid roads that are built entirely of stone, or shall be built hereafter.

S. Boyer Davis, of the legislative committee, of the Automobile Club of Philadelphia, will submit a measure providing for an increase in the automobile license fee. This measure, if it becomes a law, will, it is figured out, bring the State at least $150,000 from licenses.

To interest legislators in these various measures a committee will be appointed to circulate petitions throughout the State. These petitions will be addressed to the Senate and House of Representatives of Pennsylvania, and it is expected that upwards of 12,000 of them will be filed at the State capital.

WEST VIRGINIA MEET POSTPONED.

WHEELING, W. Va., Sept. 21.—The long-continued dry weather has made automobiling in this State such a hardship on account of the dust and general condition of the roads that the plans of many owners have been upset. In fact things have grown so bad that the annual State meet of the West Virginia Automobile Association, which was scheduled for this city during the past week, was called off. A club run to Columbus, Ohio, over the old National road had to be abandoned for the same reason, as the route selected was reported in very bad shape. There is possibility that the State meet may be held later in the fall when the roads will be in better shape, but it is probable that it will be postponed until spring.

OHIO CLUB WILL HAVE A DAY OF IT.

UHRICHSVILLE, Ohio, Sept. 19.—At a meeting of the Twin City Automobile Club, held last evening, it was decided to hold an "Automobile Day" on September 25. The forenoon has been set aside for the parade of decorated cars in which it is expected fully 100 machines will take part. In the afternoon a hill climb is scheduled, and from present enthusiasm nearly 40 cars will compete. As this is the first event of its kind in Tuscarawas county, all automobilists are planning for a gala day.

NASHVILLE AUTOISTS TO HELP CITY OFFICIALS.

NASHVILLE, TENN., Sept. 21.—Thirty of the most prominent business men in Nashville have decided that it is for their own, as well as the city's interests, that as automobile owners, they have an organiation which can work with the city officials. To this end a club was formed last week under the auspicies of the American Automobile Association, and its main object at present will be the restraint of all automobile owners in the city from violation of the State and city laws.

BALTIMOREANS WANT LAWS AND ROADS.

BALTIMORE, MD., Sept. 21.—A number of important matters were considered by the members of the Automobile Club of Maryland at the first weekly meeting the past week. First of all the dues of active members were raised from $10 to $20 annually. Associate members' rates will remain unchanged. By this means the club expects to increase its work in regard to pushing the good roads movement within the State, while it also desires to secure fair automobile laws and see to it that these are properly recognized by autoists throughout the city and State. Whether a custodian will be engaged to look after the club headquarters and the several bureaus proposed to be established under him will be decided at the next meeting.

A touring contest is looked forward to by the members, and Dr. H. M. Rowe was selected as chairman of a committee to make the necessary arrangements. President James S. Reese stated that the election of officers for the year will be held October 13, while the first meeting of the whist section of the club will take place the first Friday in October. At the conclusion of the meeting the president entertained the members at luncheon.

ROCHESTER CLUB IN NEW QUARTERS.

ROCHESTER, N. Y., Sept. 21.—The Rochester Automobile Club has just moved into its new quarters in the recently opened Hotel Seneca on Clinton Avenue Square. This new hotel, which is one of the finest in the State, will be an ideal location for the club, whose membership now numbers 525. The Board of Governors extends a most cordial invitation to members of other clubs, who may be passing through the city, to visit the new quarters, where they are not only welcome to the use of the club comforts, but they will probably find posted on the various bulletin boards useful information concerning late road conditions, police traps, etc. At present the club is warning all members of the following speed traps:

On the Summerville road near the toll house.
On the Buffalo road between Coldwater and the barge canal.
Between Cayuga and Auburn and near Camillus.

WHAT ONE PENNSYLVANIA CLUB IS DOING.

LANCASTER, Pa., Sept. 21.—In its efforts to secure good roads in Lancaster county, on the direct route from Philadelphia to Pittsburg, the Lancaster Automobile Club, at its September meeting, decided to allow its solicitor to select a man from the club for each township in the county whose duty it shall be to report to the solicitor all cases of violations of acts of assembly relating to the public highways. Particular attention will be devoted in October to the non-removal of loose stones from the roads and the neglect of road supervisors to erect at all intersections of public roads handboards legibly inscribed. The solicitor has sent to each constable and supervisor in the county a circular letter calling their attention to the law on these two subjects and advising them that these laws are in force and will hereafter be enforced. Constables are notified that if they fail to report any neglect of these prescribed duties their return will be challenged at the November term of court and objections filed against the allowance to him of any costs or mileage. In addition, measures will be taken against him for a false return and neglect of duty.

The members of the club are unanimously enthusiastic to give their solicitor their heartiest co-operation. This procedure of the club is being carried out to put the burden of responsibility for poor roads where it belongs—on the road supervisors and the constables.

In the interest of good roads the club also approved the proposition of Chairman Weeks, of the Pennsylvania Motor Federation,

for the appropriation by the State of $5,000,000 for the improvement of the highways.

The September meeting of the club was held at Lititz, and was preceded by a banquet. In connection with each monthly meeting of the club there is a banquet and the attendance always is large. The October meeting will be held at Ephrata.

For one of the younger clubs it is one of the most vigorous in the State. Through its efforts much has been accomplished to secure better roads in that section over which it has jurisdiction. The membership now is near the 200 mark.

HARTFORD MAY HAVE A 24-HOUR.

HARTFORD, Conn., Sept. 21.—There is a movement on foot to kill the forthcoming hill climb of the Automobile Club of Hartford over the Avon Mountain course and substitute therefor, a 24-hour race at Charter Oak Trotting Park. The contest committee of the local organization had practically decided to hold the hill climb on November 7th over the mountain course. The chief cause of the present agitation may be said to emanate in the success of the Brighton Beach 24-hour race. Charter Oak Park, where it is proposed to hold the local event, is at present in first-class condition and as the trotting season terminated in the recent grand circuit trotting meet, the speeding motor cars would work no material harm, as the track is soon to be fixed over. A. J. Welch, one of the owners of the park, is much in favor of the scheme, and has given assurances that the park could be secured. Such an event would be the initial attempt for the local club and it is proposed to have the meet for stock cars only. The dates proposed are Oct. 16 and 17, and it is the intention to start the cars at 4 o'clock in the afternoon, continuing until 2 o'clock the next day, leaving a lapse of two hours during which other motor car events would be run off, and then the final of the 24-hour grind would be resumed at 4 o'clock and would terminate at 6 o'clock.

SPEECHMAKING ON CLEVELAND RUN.

CLEVELAND, Sept. 21.—Interesting the farmers in a three day reliability contest, and convincing them that they should be more friendly toward the automobile, that is the task which the Cleveland Automobile Club has set itself, and during the coming reliability contect, October 14, 15, and 16, a most novel and unique plan will be pursued.

At every small town through which the cars are to pass a stop will be made of ten or fifteen minutes, and while the machines group together addresses will be made to the farmers by prominent Clevelanders who have already volunteered their services for this purpose. Some days before the contest the local club plans to advertise in the small country newspapers the fact that the contest is scheduled for their town and that a stop will be made of several minutes to allow inspection of the cars. This, it is thought, will attract a large part of the rural community, and short speeches will be made to the gathered crowd, after which "all will have an opportunity to inspect the dust covered machines which have traveled so many miles since daybreak—the chance of a lifetime to see real automobiles in a heart straining and nerve racking contest, my friends."

ASA GODDARD AGAIN AT HIS OLD JOB.

CLEVELAND, Sept. 23.—Once more the genial Asa Goddard is back in his old haunts again. When Goddard resigned from the secretaryship of the Cleveland Automobile Club some time ago, to accept the position of chief engineer of the Wadsworth Stone Co. of Pittsburg it was thought that he was done with this city for good and all.

But now he is back again, finishing the work of constructing the new Euclid road being built by the Automobile Club. He has charge of the laying of the final layers, and of smoothing up the rough portions of the work. Goddard is the man who suggested this road, and in a measure he is finishing the building of a monument to himself and the Cleveland Automobile Club.

INDIANA'S RUN UNDER GLIDDEN RULES.

INDIANAPOLIS, Ind., Sept. 21.—With a trip over the proposed route by Frank Staley, president of the Indianapolis Automobile Trade Association, and Geo. Weideley, chairman of the technical committee, last week, arrangements are practically completed for the two days' reliability run to be held in Indiana Oct. 1 and 2. The technical committee has decided to use the rules that governed the recent Glidden Tour and entries are now being received. At least 75 entries are expected.

The run will be to French Lick and return, the trip the first day being 131 1-5 miles through Edgewood, Greenwood, Whiteland, Franklin, Amity, Edinburg, Taylorville, Columbus, Azalia, Reddington, Seymour, Brownstown, Vallonia, Plattsburg, Salem, Livonia, Millersburg, Paoli, Braxton Station, West Baden and French Lick.

Returning the route is 122.2 miles long and will go through West Baden, Braxton Station, Paoli, Mitchell, Bedford, Oolitic, Needmore, Harrodsburg, Clear Creek, Bloomington, Ellettsville, Gosport, Whitaker, Paragon, Martinsville, Waverly and Glen Valley.

SOME POINTERS FOR LUBRICATION.

That proper lubrication is the life of the car has been pretty thoroughly drummed into the mind of even the tyro at automobiling. The following "Don'ts," by G. A. Haws, manufacturer of Panhard oil, give some practical pointers that are worth remembering:

1. Don't allow your motor to exhaust clouds of white smoke. Just enough oil is better than too much, and may keep you out of the police station besides.
2. Don't try to make a light oil by mixing a heavy oil with kerosene. Now that cold weather is about to set in, if the oil that you are using does not flow freely, use a lighter grade. Heavy oil thinned with kerosene is a common cause for cylinders carbonizing.
3. Don't assume that your motor is getting the proper amount of oil; make sure by examining the sight-feeds regularly. Starve a motor on oil and it may be seriously damaged even before it begins to show signs of distress by pounding or laboring.
4. Don't imagine that because you ask for a certain brand of oil you will always get it. There is so much substitution in the oil business nowadays that the wise automobilist makes sure that he gets what he asks for.

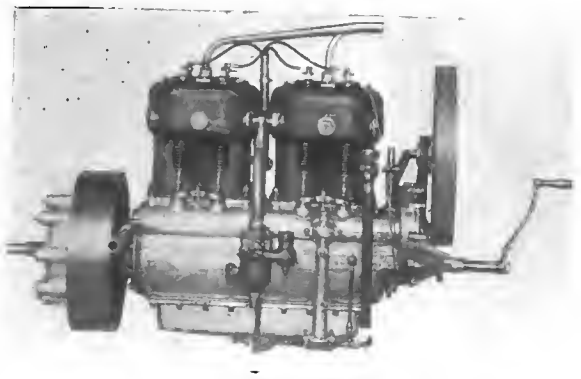
In addition, the steering knuckles and connecting rod, and the hundred and one other small moving parts should be thoroughly oiled. Ten minutes' judicious use of an oil-can every day will save an automobile owner a good many dollars in repairs and replacements at the end of the season.

MATHESON AUTOMOBILE COMPANY.

On September 12 the Matheson Automobile Company, of Wilkes-Barre, Pa., was formed with a cash capital of $150,000, to take over the entire selling end of the Matheson Motor Car Company. This company is an entirely independent organization from the manufacturing concern, which wished to be so situated that it might devote its entire time to the producing end.

At the time the selling company was organized, the manufacturing company simultaneously arranged for a bond issue of $200,000, which has already been disposed of. This means that the Matheson company will have $350,000 additional capital at its command for the manufacture of its 1909 product. To make this coming year even more marked than any before in the history of the company the services of L. C. Kenen as mechanical engineer have been engaged to design and bring out a new car, for besides the chain-driven $5,000 and $5,500 cars, which have heretofore been put on the market, it is proposed to have ready for sale at an early date a shaft-driven model selling for $3,000. The capacity of the plant will be doubled.

Arrangements have been made for desirable salesrooms on Broadway, from which point the selling company will market its cars in Greater New York and distribute throughout the country. G. W. Matheson, president of the manufacturing company, who is at present residing in Wilkes-Barre, Pa., will remove to New York and devote his entire time to the marketing.



Inlet Side of Motor of Marmon Light Touring Car.

WHAT THE MARMON COMPANY WILL FEATURE.

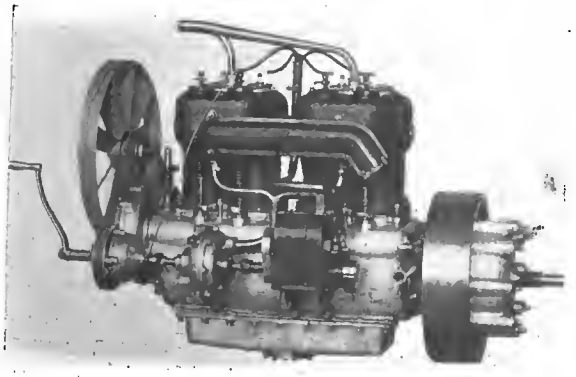
The Nordyke and Marmon Company, of Indianapolis, Ind., is preparing a light touring car of approximately 35 horsepower for the 1909 market. The photographs show the motor from either side.

That at the top of the column shows the carbureter side, and makes plain the method of supporting the motor by means of a cross tube just in front of the flywheel. The oiling connections can also be seen. The oil is forced by a pump driven from the camshaft to the main bearings of the crankshaft; it flows through ducts cut in the journals and crank cheeks to the crank pins, and finally through tubes carried by the connecting rods to the piston pins. This system enables the Marmon Company to set the motor in an inclined position and so secure a straight-line drive. The clearance may also be increased beyond the usual limit.

The lower photograph, showing the exhaust side, gives a good idea of the neatness of the design. The arrangement of the pump and the double-system Remy magneto seem particularly workmanlike.

Glens Falls, N. Y.—The Glens Falls Automobile Company has recently taken possession of the new garage which it erected on Glenn street. The building is three stories high with elevator facilities. A modern repair shop has been installed to handle local and transient trade. This company has for its officers E. F. Irish, president and secretary; W. I. Griffing, vice-president; W. L. R. Durkee, treasurer.

Harrisburg, Pa.—The Ideal Garage & Motor Car Company has opened an establishment at 906-8 Market street, with George F. Snyder as manager. The building has been remodeled and satisfies every condition of a first-class garage.



Exhaust Side of Marmon Motor, Showing Magneto.

PITTSBURG-PHILADELPHIA, 14 HOURS.

Not satisfied with having broken the automobile record between Pittsburg and Philadelphia twice this summer, S. D. Waldon, sales manager of the Packard Motor Car Company, last week went after this mountain road record again and succeeded in lowering it to the remarkable time of 14 hours 1 minute. Mr. Waldon drove the same 1909 Packard "Thirty" which he had used on his previous trips, and as usual was accompanied by four passengers, making a total load of five in the car. The passengers were W. W. Bennett and W. N. Murray of Pittsburg, and F. C. Graves and L. R. Mack of Boston. The schedule:

Miles	Place.	Clock Time.	Elapsed Time.
0.	Pittsburg	3:45	0:00—A
32.2	Greensburg	4:55	1:10
51.2	Ligonier	5:50	2:05
70.7	Stoyestown	7:05	3:20
76.8	Buckstown	7:28	3:43
90.2	Schellsburg	8:09	4:24
99.7	Bedford	8:25	4:50
107.7	Everett	8:57	5:12—B
134.2	McConnellsburg	10:23	6:38—C
142.4	Ft. Loudon	10:58	7:13
156.3	Chambersburg	11:32	7:47
180.7	**Gettysburg**	12:33	8:48
209.6	York	1:56	10:11
222.4	Columbia	2:30	10:45
233.9	Lancaster	2:57	11:12
260.6	Coatesville	4:08	12:23
266.9	Downington	4:20	12:35
294.3	City Line	5:26	13:41
302.4	Philadelphia	5:46	14:01

Only Stops.—(A) blocked railway crossing, 2 minutes; (B) for coffee, 3 minutes; (C) for gasoline, 7 minutes.

S. D. Waldon and Cross-Pennsylvania Party.

AN AMERICAN MANUFACTURER ABROAD.

Thomas B. Jeffery, whose long experience makes him a dean in the automobile industry of America, and whose name has been connected with the word Rambler for over twenty-eight years, has just returned from a three months' tour through Scotland, England and Germany, where he took the opportunity of investigating some of the manufacturing methods of foreign countries. The most striking feature to him was the fact that almost no attempt was made there to build a machine at what we consider a popular price. The machines are heavy and only those with a large income can afford to own one. He decided that the cost of production was high, largely because of the comparatively small number built, and the fact that the real manufacture of the car was distributed among a variety of concerns, the machine itself being little more than an assembled car.

An interesting thing happened during his tour of England which illustrates how useless a car from that country would be in America. The Rambler builder in making his little local trips hired various cars of various makes and while passing along the road one day while in England, he noticed a tin mine a short distance from the road, which could only be reached by going over a rather rough road. On his requesting the driver to turn in so that he might inspect the mine, he was informed that to go up that road would tear the under portion of the car to pieces, because the rocks in the road were too high.

Testing Out the Chalmers-Detroit on the Famous Grosse Pointe Track, Detroit.

Race Track as Testing Ground.—Since the Chalmers-Detroit Motor Company has begun to make deliveries of the new "30" model, they have had so many cars out for testing purposes that it became necessary to procure some place where a large number of machines could be tested out at high speed. After some negotiation with the track raeing committee of the famous Grosse Pointe traek, permission was obtained for the use of this mile circuit for testing out of ears. As it is only a short distance from the factory it is very convenient and every day fifteen to twenty machines are given a long track test in addition to the road test.

A Strenuous Pope-Hartford Trip.—Rather a strenuous flying test trip was recently completed by W. C. Walker, seeretary of the Pope Mfg. Co., Assistant Superintendent Seymour, James Grady, the well-known driver, and Mechanie Houston. They left the Hartford Club at 1 P.M., and passed through Providence and Boston to Newburyport, where they spent the night. Early the next morning they were on the road again and continued on to Portsmouth; then striking inland, they made a circuit round Lake Winnipesaukee and returned through Worcester and Springfield to Hartford. In all they covered 600 miles in a day and a half.

National Battery Co. Affairs.—Announcement is made by the National Battery Company, of Buffalo, that the receivership under which the company has been working for the past eight months was terminated August 19, and the entire property has been restored to the stockholders. Full control of the reorganized company has been secured by the Cutler-Hammer Manufacturing Company, of Milwaukee, well known as makers of battery charging rheostats and other electrical controlling devices. The plant of the company will remain at Buffalo, but the business will be conducted under new management.

Greatest Industry in Syraeuse.—The H. H. Franklin Manufacturing Company objected to the statement made in a Syracuse paper that the greatest single industry in Syracuse is the manufacture of clothing. The clothing concerns did a $3,000,000 business last year, but the Franklin company beat that figure by a million. This is for the year ending September 1. J. E. Walker, of the big automobile eoncern, says that in the last seven years over 6,000 machines have been built at the factory. In 1902, when the concern was organized, thirteen runabouts were built, the total value heing $15,600, and thirteen men were employed at the work. The payroll now contains the names of 1,500 men. Next year the concern expeets to add to its output a number of commercial vehicles and motor cabs.

A. L. A. M. and Standard Rims.—When seen regarding the report that the Licensed Association had decided upon the adoption of a certain form of quick detachable rim, Albert L. Pope, chairman of the tire committee of the association, said: "It is hardly to be expected that the Licensed Association as a body, with the far-reaching influence that its actions necessarily have, would take precipitate action. They have not as yet taken any action, specifically adopting any particular type of quick-detachable rim."

Another New Car Coming.—The announcement eomes from Muncie, Ind., that a new factory for the manufacture of automobiles will be started in this place as soon as the title to the site for the plant can be obtained. The project is being financed by Thomas F. Hart and Madison Maring, of this city, and outside interests. Although no definite details have been given out, it is understood that they have obtained the rights on a car which has been successfully marketed for a number of years.

Stoddard-Dayton Wins Three.—At San Francisco last Saturday, in the nresence of 20,000 people, a Model K Stoddard-Dayton, which sells for $2,500, won three events on the program, going out of its class in two of them. This machine won in the event open to ears costing $2 000 to $3,000 for 10 miles, also the race open to those costing $3,000 to $4,000 for the same distance, and the free-for-all against a field of six machines.

New Swinehart Buggy Tire.—To meet the demand for a special autobuggy tire the Swinehart Rubber Company has put on the market a tire of its regular clincher design in sizes adapted to these cars. It is made larger than the ordinary carriage tire, of specially compounded and cured rubber, which gives it greater resiliency, and the grooved side design permits a wider tread, affording better traction in mud and sand.

New Home of Invader Oil.—During Founders' Week at Philadelphia, Charles F. Kellom & Co., manufacturers of "Invader" oils, will be at home in their new location, 113 Arch street. The building has been entirely remodeled both inside and outside, and affords much better accommodation for the increasing needs of the business than the old quarters further up the street.

Visiting the Franklin Plant.—Henceforth the many visitors at the H. H. Franklin Manufacturing Company's factory in Syracuse, N. Y., will be given a personally conducted tour by experienced guides, who will explain in detail how the Franklin car is constructed. Many of the principal parts will be shown to illustrate how systematically the manufacture is carried on and how carefully every piece is inspected and tested.

The Other Side of the Story.—The Winton Motor Carriage Company has in press a booklet explaining their views on the light weight question. Although admitting every argument put forward in favor of light cars, they believe that the advantages of heavy weight cars are more important. The book is well illustrated and will be ready for distribution within a week.

Mora Company Election.—Last week, at the annual stoekholders' meeting of the Mora Motor Car Company in Newark, N. Y., the following officers were elected for the coming year: S. H. Mora, president; T. W. Martin, viee-president, and W. N. Freeman, secretary and treasurer. A resolution was passed reducing the number of directors from seven to five.

E. M. F. Cars in New York.—H. J. Koehler, the New York agent of the Everitt-Metzger-Flanders Company, has just returned from a trip to the factory in Detroit. He has contracted for 1,000 E. M. F. cars for distribution in his territory, which includes New York City with ten adjoining counties and the State of New Jersey.

Cleaning Up the Dietzmans.—The United States Circuit Court has notified Joseph Harris, as trustee for the bankrupt Dietzman Shock Ahsorher Company, to dispose of 150 sets of these absorbers as soon as possible. This constitutes the remainder of the stoek on hand in the possession of the trustee.

Densmore Company of Buffalo.—A new firm, to be known as the Densmore Company, has just heen incorporated in Buffalo with a capital stock of $15,000 and will deal in automobiles. The incorporators are W. R. Densmore, of Buffalo, and Fred Densmore and F. Sturtevant, of Erie, Pa.

Tires for the Roval Car.—The Continental Caoutchouc Company has been informed by their home office that His Majesty, the Emperor of Austria, will be presented with two automobiles, both equipped with Continental tires, to commemorate the sixtieth year of his reign.

Shock Absorbers at Brighton.—Cars equipped with Truffault-Hartford shock absorbers took first, second and third places in the 24-hour race on the Brighton Beach track last Saturday. The winning Lozier used them for the first time, although it has competed in many other contests.

Atlanta to Have Taxieabs.—Capitalists of Atlanta, Ga., exoect to shortly incorporate the Atlanta Taxicab Company, with a capital stock of $12.000, to operate cabs on the city streets. Ten machines will be purchased to begin with.

Grand Central Palace Show Poster.

One of the most artistic show posters ever brought out is the one-half sheet lithograph of the A. M. C. M. A., under whose management the Ninth International Automobile Show will open New Year's Eve in Grand Central Palace. Eight different colors have been embodied in the scheme. It is arranged so that no printing is placed on the pictorial part, which can be cut out and framed.

IN AND ABOUT THE AGENCIES.

Pennsylvania.—The Pennsylvania Auto Motor Company announces that it has just concluded arrangements with J. M. Quinby & Co., carriage builders, of Newark, N. J., to distribute Pennsylvania cars in northern New Jersey, New York City and vicinity. The Quinby company will open a large showroom in New York and will handle the Isotta also. A specialty will be made of furnishing Pennsylvania cars with special Quinby bodies.

Mitchell.—Having outgrown its present quarters at 236 North Broad street, Philadelphia, the Penn Motor Car Company has secured a lease on the three-story building at the northwest corner of Broad and Cherry streets, and after necessary alterations will move into its new quarters, possibly about October 1. Manager Walter Cram says his company has contracted to dispose of at least 300 Mitchells during the next twelve months.

Jackson.—The Jackson Motor Car Company of Philadelphia has been organized to look after the interests of the Jackson car in the Quaker City. Quarters have been secured with Prescott Adamson, at the northwest corner of Broad and Spring Garden streets, where the Columbia and Renault are also handled.

New Packard Quarters.—The Packard Motor Car Company of New York has leased the Osborne Realty Company's store at Brantford and Treat place, Newark, N. J., for their branch in that city.

New Tire Concern.—The W. D. Spring Cushion Tire Company of Philadelphia has filed articles of incorporation with a capital stock of $250,000 and will manufacture tires for all kinds of vehicles.

Studebaker.—John A. Bersenger, builder and dealer in carriages and owner of an automobile repair shop in Huntington, N. Y., has taken the agency of the Studebaker for 1909.

Pierce Arrow.—Henceforth the Ellis Motor Car Company, agents for the Pierce Arrow in New Jersey, will be located at 124-126 Washington street, Newark, N. J.

PERSONAL TRADE MENTION.

Wagner-Field Company.—Fred J. Wagner, until recently with *Motor Age*, and Russell A. Field, late auto editor of the Brooklyn *Daily Eagle*, have established an advertising service in the Thoroughfare Building, 1777 Broadway, New York City, under the name of the Wagner-Field Company. The motor car and interests allied with its sale and manufacture will be made a specialty.

George M. Davis has been placed in charge of the George N. Pierce Company's publicity department. Mr. Davis is generally recognized among the most efficient press agents connected with the automobile industry. He formerly occupied that position with the E. R. Thomas Motor Co.

J. E. Doane, for the past two years Syracuse representative of the H. H. Franklin Manufacturing Company has added to his field of activity that part of New York State east of Rochester to the Hudson River.

C. E. Apgar, formerly in the employ of the New York branch of the Franklin Automobile Company, has resigned from that concern, and joined the New York force of the Haynes Automobile Co.

G. A. Winslow, who has been for nine years past with the Boston Cycle & Sundry Company, Boston, Mass., has joined the forces of the Boston branch of the Pennsylvania Rubber Company.

F. F. Neaver, who for a number of years has been sales manager for the Studebaker Brothers Mfg. Co., is going to take charge of that company's branch at Portland, Ore.

Carl J. Simons has resigned as manager of the Palace Auto Company of Kansas City, Mo., and will become manager of the Maxwell-Briscoe branch October 1.

C. F. Stimson, formerly of Kansas City, Mo., is to be appointed manager of the new branch of the Maxwell-Briscoe Company in Minneapolis.

H. D. Benner, recently appointed Philadelphia agent for Michelin tires, will shortly open well-equipped quarters at 320 North Broad street.

DEATH OF VALENTINE B. LANG.

HARTFORD, CONN., Sept. 22.—Valentine B. Lang, vice-president of the Hartford Rubber Works Company, died suddenly at his home in this city this noon. He arrived home this morning from a trip to Columbus, O., but did not complain of feeling ill. After lunch he had an attack of heart trouble, which resulted in his death.

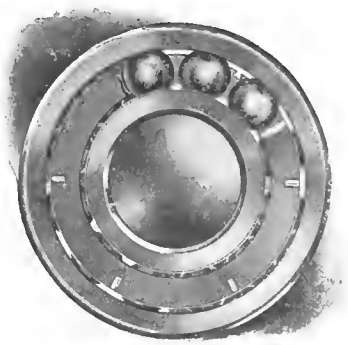
Mr. Lang was born in New York, July 18, 1858. Twenty-five years ago he entered the employ of the West Shore Railroad, as foreman of the machine shop, under the late Charles H. Dale. Mr. Lang next became assistant superintendent of the Chicago & Alton Railroad, and afterwards master mechanic of the C. N. O. & T. P. Railroad, at Chattanooga, Tenn. From there he went to Birmingham, Ala., where he was connected with the Great Southern Railway. From Birmingham he went with Morgan & Wright, and had charge of their new plant at Detroit. Two years ago he came to Hartford as factory manager of the Hartford Rubber Works Company, and in 1907 was promoted to be vice-president. He is survived by his wife. Mr. Lang was a thirty-second degree Mason, and belonged to the Knights Templar Commandery in Detroit.

Branch Managers and Field Representatives, Hartford Rubber Works Company.

Standing, left to right—D. W. Shattuck, G. D. Niles, G. R. Noble, F. J. Kerner, H. E. Field, vice-president; Charles Kenyon, A. D. Cruden, J. J. Tompkins, Charles Clark, D. W. Pinney, E. H. Fahy, F. B. McClunie. Top row, sitting, left to right—Charles Langmaid, George Orr, W. T. Powell, W. H. Reed, W. R. Barnes, H. C. Severance, H. F. Snyder, E. S. Roe, Second row, sitting left to right—H. Barth, Jr., E. W. Culver, E. H. Johansen, J. P. Krogh, A. L. Lowe, W. H. Bell, P. H. Goodall. Lower row, sitting, left to right—H. B. McIntosh, W. Brown, M. C. Stokes, H. E. Smith, R. H. Gillies, J. D. Anderson, president; H. Plow, treasurer; F. Kesser, A. W. Kirk.

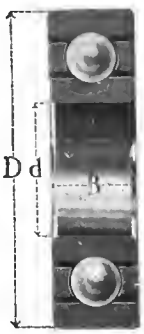
INFORMATION FOR AUTO USERS

New Annular Ball Bearing.—A new type of "silent" annular ball bearing which possesses some special advantage over preceding types is shown in the accompanying illustration. This new bearing is made by Fichtel & Sachs, of Schweinfurt, Germany,

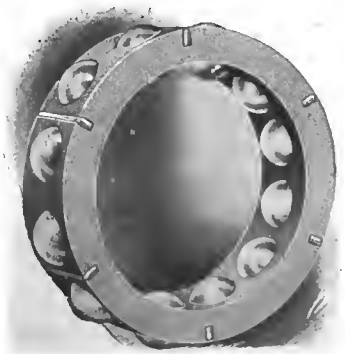


VIEW SHOWING BALLS EXPOSED.

and it resembles former ball bearings made by that well-known firm in respect to the method of introducing the balls. This method, as users of these bearings know, is to form angular entering grooves in the sides of the inner and outer races, and after the bearing is half filled to introduce the remaining balls by way of these grooves. Contrary to a possibly common impression, these side grooves are not quite as deep as the races themselves and therefore the balls are sprung in under some pressure. Once in they do not touch the side grooves, and even if they did the fact that the grooves are angular would prevent them from tending to escape. So far as the ball "knows" the side grooves are no longer there. This construction presents obvious advantages over that in which the races are so shallow that the balls may be sprung in from any point, since such races are usually too springy to endure material



CROSS SECTION VIEW.



F. & S. BALL-CARRYING CAGE.

end loads, whereas bearings constructed in the manner above described will carry end loads from 1-10 to 1-4 of their radial load capacity. It also permits a larger number of balls to be used than when, as a bearing, without side grooves, only half the races are filled with balls. In the new type of bearing the distinctive feature is the separator, which is so formed as to permit almost the entire space to be filled with balls. The separator is die-cast of a special alloy and requires almost no machining. It is split in the central plane of the balls, and the two halves are united by brass wires or dovetail section, which are inserted in dovetail-shaped grooves and have their ends clinched over into notches in the sides of the separator. From the illustration it is seen that the loss as compared with the "full" type is only one ball. The makers of this bearing lay special stress on the high quality of the materials used and on the extreme accuracy of workmanship and sizing. It is obvious that a bearing such as the one described, having more than the usual number of balls, should distribute its load among several balls instead of concentrating it on three or two, or even on a single ball. To realize this, extreme accuracy in both balls and races as well as perfect uniformity in size of balls is necessary. Fichtel & Sachs claim to have made this degree of accuracy a matter of commercial practice. These bearings are imported by J. S. Bretz Company, Times Building, New York City.

Motorlube Oils.—"Perfect automobile lubrication means the reduction of carbon without materially reducing the lubricating qualities of a pure Pennsylvania petroleum. A few years ago it was thought a heavy viscous oil would give better lubrication than the so-called light oil, which is not true," says B. S. Mellor, manager of the E. A. Tygert Company, makers of motorlube oil, 614 Chestnut street, Philadelphia, Pa. "The viscosity of a very heavy oil is very great at low temperature, but the very high temperature of the cylinders must be considered. Below are some relative viscosity tests of heavy and light oil:

	70 F.	140 F.	200 F.	300 F.	400 F.
Heavy	3100 sec.	253 sec.	75 sec.	40 sec.	21 sec.
Light	1270 sec.	135 sec.	52 sec.	35 sec.	20½ sec.

The above tests go to show that at 400 degrees F. the light oil has practically the same viscosity as the heavy. It is well known that a light colored highly filtered oil has less carbon than the heavy loaded dark colored oils, and it is my opinion that a light oil of sufficient viscosity is better in all respects for automobile lubrication than a heavy oil."

New Feature on Speedometer.—One of the features of the new Peerless Speedometer, which has just been placed on the market by the Peerless Specialty Company, 1876 Broadway, New York City, is that the season's mileage cannot be altered except by sending the instrument back to the factory, thus making it impossible for any one to run a machine with one of these instruments attached without the owner's knowledge.

The Utility of "Permanit."—In the issue of THE AUTOMOBILE for September the statement was made that "Permanit," manufactured by Adolph Karl & Company, of Newark, N. J., would prevent blowouts. From the nature of the substance this is manifestly impossible, but the manufacturers do assert that it will neutralize the effects of punctures by immediately healing them through chemical action.

"Oilzum."—The White & Bagley Company, Worcester, Mass., has recently put out a little device which will undoubtedly prove very convenient to a great many auto users. This appurtenance consists of a bracket, as shown in the illustration, for holding a can of oil on the running board. The lower end of the bracket projects under the running board and is fastened by two brass screws, so that the top of the board is not marred, and the bracket may be put in place or removed on a moment's

WHITE & BAGLEY DEVICE FOR CARRYING CAN OF OIL.

notice. By attaching another bracket to the back of the running board, two cans may be carried, the strap being brought clear over the two cans. Many tourists have found that at times it is convenient to have a good supply of oil on hand, but have sometimes found difficulty in carrying it handily. This arrangement should help them out, and the manufacturers will furnish these brackets free of charge to all users of their carbonless cylinder oil.

Improved Methods in Lens Mirror Manufacture.—The problem of manufacturing a permanent silvered surface for the reflectors of the acetylene lamp has baffled the producers from the first. The common opinion has been that the difficulty was in the proper silvering of the mirror, but Stevens & Co., Providence, R. I., manufacturers of the thermo mirror reflectors, claim to have discovered that the trouble comes, not from poor silvering, but from the fact that because of the difference in material of the backing unequal expansion took place between the glass and these materials. When this took place the perfect contact between the glass and the silver was disturbed, allowing moisture to creep in, which caused oxidization and the consequent loss of the reflecting power. To remedy this Stevens & Co. have produced a combination of backing materials which, when applied upon the surface of a lens mirror, they maintain will expand and contract in unison, insuring perfect contact under all conditions between silver and glass.

Nine Lives.—The Empire Automobile Tire Company, of Trenton, N. J., is sending to its friends in the trade a poster in colors showing a pussy cat with a blue bow on its neck sitting in the middle of a 36x4 Empire clincher tire. The implication is, of course, that the tire, like the pussy, has nine lives.

Vol. XIX New York—Thursday, October 1, 1908—Chicago No. 14

THE AUTOMOBILE

NEW ENGLANDERS HAVE REAL 24-HOUR STRUGGLE

Franklin Which Carried No. 13.

BOSTON, Sept. 30.—There have been Glidden tours that needed several days and many miles of added driving to eliminate the winners from big fields of starters, but no endurance run of the one-day type has ever required so gruelling a postscript of road plugging to evolve a winner as has that of the Bay State Automobile Association, which started last week Wednesday night, September 23.

Nine of the 21 cars evolved with perfect scores in the original run from Boston to Bretton Woods and return, which started Wednesday night at 10 o'clock and concluded the following evening with the contestants having been on the road 22 hours and 15 minutes for the 386-mile journey, though some of the cars covered more than 400 miles by going astray.

These were the perfect score cars: Franklin, Studebaker, Marmon, Oldsmobile, two Shawmuts, Reo, Buick, and Lancia. The clean-score cars were immediately locked up in the White Garage and the drivers and entrants notified to meet Friday at 2 P.M. at the Bay State clubhouse. It was then decided that the battle would be continued to a finish. Two contenders then withdrew.

Shawmut Runabout, Church Driving.

Tied Cars Reduced to Four in Number.—Boston, Sept. 26.—While the winner was decided in the first day's run-off, which was accomplished partially in a fog, only four finished the day without a mark, these being the Franklin, Studebaker, Marmon, and the Shawmut runabout. The unfortunates were Lancia, Oldsmobile, and Shawmut tourer, all of them meeting with mishaps.

One Out on the Second Run-off.—Boston, Sept. 28.—In the second run-off from Boston to Portland and return, 240 miles, F. E. Wing's Marmon lost a wheel in a ditch near Wells. The Studebaker, Franklin, and Shawmut have covered 958 miles.

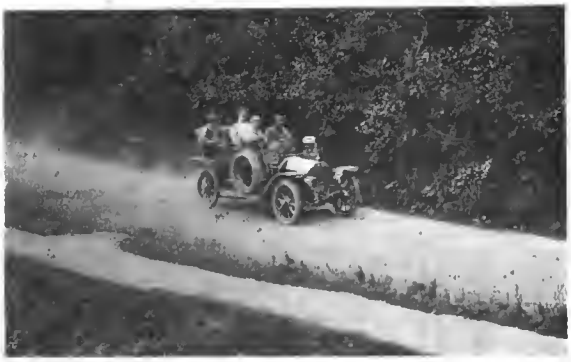
Studebaker, W. G. Jones Driving.

None Out on Third Day Continuation.—Intervale, N. H., Sept. 29.—Without mishap of any kind, the Franklin, Studebaker, and Shawmut tied trio arrived here to-night via Portland, Poland Springs and Fryburg. According to the drivers, the day's run was the hardest thus far.

The cars are scheduled to leave here at 6 o'clock Wednesday morning for Boston via Crawford Notch, Bretton Woods, Bethlehem, Franconia Notch and Concord. They should finish about 7 p. m.

The original plan was to hold a twenty-four-hour test over the roads from Boston to Bretton Woods, in the White Mountains, and return, and to give the clean score cars certificates of merit. Then a member of the association offered a $200 cup to be awarded to the winning car, and this made it necessary that a winner be determined. To this end it required that the test be definitely

Marmon, with Wing at the Wheel.



Oldsmobile Touring Car, Driven by Hobson and Schneider.

continued until but one clean score car should survive. The run started at 10 o'clock Wednesday evening from the Bay State Automobile Association. Of the twenty-two cars that had been entered, twenty-one showed up for the send-off. They were:

Touring Cars.

No.	Car.	Entered By.	Drivers.
1.	Pierce	Harry Knights	Harry Knights.
2.	Marmon	F. E. Wing	F. E. Wing.
4.	Lancia	Hol-Tan Co.	W. M. Hilliard.
6.	Buick	Buick Motor Co.	W. L. McCain.
7.	Shawmut	Shawmut Motor Co.	Arthur Ayres.
13.	Franklin	Franklin Auto Co.	Carris and Burns.
14.	Studebaker	Studebaker Auto Co.	W. G. Jones.
15.	Cadillac	A. T. Fuller.	H. L. Smith.
16.	Oldsmobile	Algonquin Motor Car Co.	Hobson and Schneider
19.	Stevens-Duryea	J. W. Bowman Co.	G. Canterbury.

Runabouts.

No.	Car.	Entered By.	Drivers.
3.	Buick	A. H. Waitt.	A. H. Waitt.
5.	Lancia	Hol-Tan Co.	Harry Fosdick.
8.	Shawmut	Shawmut Motor Co.	Harold Church.

22.	Buick	Buick Motor Co.	C. H. Coakley.
23.	Reo	J. M. Linscott Co.	Fred Pratt.

The confetti car was a Knox, and the official cars were a Stevens-Duryea and a Royal Tourist. Each competing car carried an observer, and there were checking stations at Rochester, 90 miles from Boston; Bretton Woods, 182 miles; Concord, 283 miles, and Boston, 359 miles. At Bretton Woods an hour and a half stop for luncheon was made, and it was permitted that the motors be stopped. The time of arrival of the first car in Boston was 8:45 P. M.

Of the 21 starters, 15 finished, and 9 of these had perfect scores. The successful cars were the Marmon, Shawmut, Franklin, Studebaker, and Oldsmobile, in the touring class, and the Lancia, Shawmut, Reo, and Buick in the runabout division. The Franklin was the only air-cooled car in the test and it went through with flying colors. The Lancia engine was sealed, and was not stopped during the entire run. After reaching Boston, Harry Fosdick continued to keep the engine running until it had been in operation for a complete 24 hours.

Lancia Runabout, with Harry Fosdick at the Wheel.

The Pierce car, driven by Harry Knights, was a 1906 type that he had driven previously over 30,000 miles, and it suffered only a two-point penalization. Going up a long hill near the Profile in the White Mountains, the gas tank failed to feed the carbureter because of low pressure, and the engine was stalled for two minutes. The No. 3 Buick lost five points for stalling the engine before the first control was reached, and another point for similar trouble before the second control. It was not reported beyond Bretton Woods. The Lancia, driven by W. M. Hilliard, was tied up nearly an hour on the outward leg by reason of the carbureter becoming clogged with dust. After locating and remedying the trouble, Hilliard struck a cup race gait and landed in Bretton Woods ahead of everybody else. On the way back the engine stalled, costing the car a slight penalty. The No. 6 Buick had a clean score at Bretton Woods, but after passing Plymouth it had the misfortune to get into a mix-up with a skittish horse, and both automobile and horse were put *hors de combat*, the car being unable to finish.

The No. 9 Overland reached Cambridge with a clean score. Then, when only two or three miles from the finish, in turning out of a car track the car skidded and a wheel collapsed. The No. 10 Overland had varied troubles, and finally quit at Bretton Woods, with 31 points against it. The Chalmers-Detroit also was unfortunate. Carbureter trouble cost it 7 points, stalling the engine 7 points, and transmission troubles 82 minutes.

The Rambler had only one point scored against it, the motor being stopped for 25 seconds by dust that clogged the intake valve near Bristol on the return journey. The Cadillac lost 1 point for stalling of the engine, and 21 for being late in Boston. On the way to Boston the driver twice lost the road. While consulting a signboard, the driver of the Corbin accidentally stalled the motor, which cost his car two points. It was stuck in the sand above Concord, and was 17 minutes late at the control. It was also late at Boston. The driver also lost his way.

The only woman in the tour was Mrs. Mabel Stearns, of York Harbor, Me., at the wheel of an Overland. She lost 27 points to Bretton Woods, and was not reported thereafter. The carbureter, a stalled motor, and gas pipe troubles accounted for her bad score. The Stevens-Duryea, after passing the Rochester control, sprung a leak in the gasoline tank, and the gas all disappeared, leaving the car stranded in the woods. After much delay the hole was plugged, and sufficient gasoline was obtained to bring the car back to Boston by the route it had followed on the outward trip.

The official cars had their share of trouble also. The confetti car had magneto trouble near Rochester, and the confetti was taken up by the Stevens-Duryea, which carried it the rest of the way, making all controls on time and having no trouble. The Royal Tourist was often delayed by tire trouble. The roads were very dusty, which interfered with the engines and stung the eyes and faces of the drivers and passengers. Owing to the protracted drought also, the roads were very rough, and the passengers and observers in the rear seats had a hard trip.

The official result of the first day's run was as follows:

No.	Car.	Entered By.	Penalization.
2.	MARMON	F. E. Wing	Perfect.
5.	LANCIA	Hol-Tan Co.	Perfect.
7.	SHAWMUT	Shawmut Motor Co.	Perfect.
8.	SHAWMUT	Shawmut Motor Co.	Perfect.
13.	FRANKLIN	Franklin Auto Co.	Perfect.
14.	STUDEBAKER	Studebaker Auto Co.	Perfect.
16.	OLDSMOBILE	Algonquin Motor Co.	Perfect.
22.	BUICK	Buick Motor Co.	Perfect.
23.	REO	J. M. Linscott Co.	Perfect.
12.	RAMBLER	T. J. Jeffery & Co.	1 point.
1.	PIERCE	Harry Knights	2 points.
15.	CADILLAC	A. T. Fuller.	21 points.
17.	CORBIN	Corbin Motor Co.	25 points.
4.	LANCIA	Hol-Tan Co.	74 points.
11.	CHALMERS-DETROIT	Whitten-Gilmore Co.	96 points.
3.	BUICK	A. H. Waitt.	Did not finish.
6.	BUICK	Buick Motor Co.	Did not finish.
9.	OVERLAND	Frank Wentworth	Did not finish.
10.	OVERLAND	Frank Wentworth	Did not finish.
18.	OVERLAND	Mrs. Mabel Stearns.	Did not finish.
19.	STEVENS-DURYEA	J. W. Bowman Co.	Did not finish.

MILWAUKEE'S "24" WON AGAIN BY LOCOMOBILE

MILWAUKEE, Wis., Sept. 27.—For the second time the Locomobile has won the annual 24-hour Milwaukee track race, a 40-60-horsepower roadster, driven by Bob Drach and Fred Leiser, finishing first in the long grind which was contested Friday and Saturday on the State Fair Grounds track. The Locomobile ran up a total of 992 3-4 miles and led a 20-horsepower Mitchell by a big margin, the Racine machine recording 808 3-4 miles. Third was the White Steamer, with 712, while the Midland was fourth with 693 1-2. The Buick runabout had 519 3-4 miles. Three other cars started—a two-cylinder Jackson, a four-cylinder Maxwell, and a Petrel, the last a new friction-drive production.

Conditions were different from those of last year, for the two-car team proposition was abandoned and instead it was a one-car race. It was a continuous performance, too, there being no intermission for short distance races as was the case at Brighton Beach. Interest in the affair at the start was centered in the Locomobile and the White, this being the first appearance of the later in a 24-hour race.

The Maxwell was an important factor at the start. It jumped into a duel with the big Locomobile and fought every inch of the way for the first 45 minutes. Then it ran into the fence in the backstretch and was down and out with a punctured radiator and a broken flywheel. Then the Mitchell became aggressive, and at the end of the first hour it had the honor of leading the field. The Locomobile then warmed to its work, and at the end of the second hour was on even terms with the Mitchell, finally pulling away, and was never headed thereafter.

Only two accidents marred the race, the Maxwell and the Jackson being the sufferers. The latter went out at 8 o'clock Saturday morning, when it crashed into the fence on the first turn. No one was injured in either accident.

Compliments of all sorts were handed out to the hard-working officials of the Milwaukee Automobile Club for the manner in which they handled the big race. Apparently nothing had been overlooked and there wasn't a hitch from start to finish. Forty-four officials, counting the reliefs, were on duty, with Chairman Dearholt, of the racing board, and Secretary Drought "on the job" from start to finish. The club scored an innovation by securing twenty members of the state militia for guards and well did they do their work, no one but officials or contestants being allowed on the track, while at the paddock passes were necessary in order to get past the dead line.

The arrangements for checking the progress of the race worked perfectly, the milage being recorded by means of street car registers, the same as was done last year. Each car had a register and as it finished a lap an attendant pulled a string, which rang a bell and recorded the mile.

The track and grounds were lighted by Avery gas tanks, there being 150 of them in service. On the track these were placed at about 35-foot intervals, with a common wash basin acting as a reflector. They were so turned that they flashed the light ahead, so that the drivers were not blinded by the light.

Every car in the race was allowed to put on extra gasoline and oil tanks, which technically violated the racing rules as regards stock cars. The Locomobile had its extra tanks on the rear, all of them big brass affairs which made the car resemble a chemical fire engine. The gasoline tank held 22 gallons, and there was a 6-gallon oil tank and two acetylene gas tanks, making a formidable battery. Like all the others two tail lights, fed by acetylene gas, were used. The White steamer just doubled its water and fuel capacity, the first by means of a 6-foot affair which was placed on the running board and looked like an extra-long tool box. In addition there was a gasoline tank on the rear of the chassis, which gave the White a capacity of 40 gallons of water and the same in gasoline. It was this extra equipment that proved the undoing of the steamer. This was the first 24-hour race in which it ever had taken part and its

Fuel Tank Arrangement on the Winning Locomobile.

entrants were not prepared for it. F. W. Gregory of San Francisco entered the car and it was shipped here from Denver, where it had been a contestant in the Labor Day road race. It only got here the day before the race, and there was no chance to try it out. When it did get into the actual race it was discovered that the two extra tanks seriously interfered with the draught system, necessitating frequent stops because of overheating of the burners.

The Mitchell carried a 35-gallon gasoline tank, while the Buick had an extra 5-gallon tank. The Maxwell had 15 gallons "up its sleeve." The Midland carried an extra 10 gallons as well as 5 gallons of oil. The Jackson packed 8 extra gallons of gasoline and 3 gallons of oil.

Fisk demountables were fitted to the Locomobile, Mitchell and White, while the Midland and Buick had Firestones. Goodyears were on the Jackson and Ajax on the Maxwell. The demountables proved great timesavers, fast work being done in changing. As an instance of the speed possible a right front on the Loco was changed in 1 minute 20 seconds.

HOW THE CONTESTANTS PROGRESSED AND FINISHED IN THE MILWAUKEE 24-HOUR RACE.

CALIFORNIANS HAVE A TRACK MEET.

San Francisco, Sept. 21.—The holding of the second annual track meet of the Olympic Club proved even a greater success, as far as records and enthusisam is concerned, than was the initial event of last year. The races were held on the Tanforan race track Sunday, September 20, and passed off without an accident to mar the sport. Over three thousand persons motored to the track, which is located in San Mateo County, a few miles from this city, and extra trolley cars and a special train conveyed large crowds, until fully 10,000 were on hand.

The best time of the day was made by the White steamer, when it encircled the mile track in 1:02. The fastest five miles made by any of the cars was scored by the Stoddard-Dayton, when it covered the second five miles in the third race in 5:31, and the fastest ten miles was made by the same car in the same event, making the entire distance in 11 min. 11 2-5 sec.

In the five-mile handicap race for members of the Olympic Club, three cars faced the starter. M. L. Rosenfeld, driving a Peerless, won in 6:07 1-5, with M. Boas, in a Thomas, second. The third race for stock cars listed at the factory for $2,750 and under, was participated in by four starters—a Stoddard-Dayton, driven by Wiseman; a Chalmers-Detroit, with Bert Dingley at the wheel; a Buick, and a White steamer. The Stoddard-Dayton took the lead, and for a little while was worried greatly by the Chalmers-Detroit, but the Stoddard-Dayton gradually drew ahead until it had a safe margin, which it kept, the Buick coming in third and the White fourth. The time of the winning car was 11:11 2-5.

In the 10-mile race for stock cars listed at $1,500 and under, Howard, in a Buick, was the winner. Time, 12:10 2-5.

The sixth race was the most exciting event of the day. Bert Dingley sent the Chalmers-Detroit ahead at the drop of the flag, followed by the Stoddard-Dayton. For over two miles it was a close struggle, but the Stoddard-Dayton in the third mile passed the Chalmers-Detroit, and held the lead to the end. Time, 11:25.

In the race for stock cars listed at $3,500 and over, there were three starters—a Thomas, Peerless and a White steamer. The White took the lead and held it to the end. A 60-horsepower Thomas touring car held second place until the fourth mile, when the Peerless got by it. Time, 12:16.

In the ten-mile free-for-all, a White, two Comets and a Stoddard-Dayton faced the starter. The latter took the lead at the start, with the Comet close up. The White looked like a winner, when suddenly something went wrong with the generator, necessitating its withdrawal from the race. The Stoddard-Dayton finished first, with Cooper's Comet second. Time, 11:23.

ANOTHER CUBAN ROAD RACE IN FEBRUARY.

Havana, Cuba, Sept. 22.—Another great automobile road race is on the eve of promotion by Havana enthusiasts. The date at present tentatively chosen is the early part of February. This will not only follow the close of the running races, but will be near to the height of the West Indian and Floridian resort seasons. The Cuban Automobile Association, which is behind the project, has secured the promised co-operation of Governor Magoon and the local authorities. The agitation for another international race is somewhat due to letters from Thomas Francis Moore, of New York, identified in the promotion of the Briarcliff race, and W. J. Morgan, who was instrumental in getting up the two former Cuban contests, urging a renewal of the international contests of 1906 and 1907. These gentlemen promise to give the race wide publicity and to bring over from the United States crack cars and drivers. E. W. Dennison, secretary of the Publicity League of Cuba, is interesting himself in the project.

Arrangements are being made to raise a prize guarantee fund. This time it is proposed to run the race on a 28-mile circuit instead of a straightaway stretch, as was done in the former contests. This is made possible by the extension of the good roads system in this province.

STEARNS WINS A BERKSHIRE CLIMB.

Pittsfield, Mass., Sept. 26.—The hill climbing contest held under the auspices of the Berkshire Automobile Club this afternoon over the State Road Boulevard, up Snake Hill and South Mountain, was brought to a close without a serious accident. For three hours the road was closed to the public and over two thousand people assembled to watch the many cars and motor cycles negotiate the difficult turns. The feature event, the free-for-all, open to cars costing from $2,000 to $3,500, was won by a Stearns, with Phillip Rosenbaum, of Florida, at the wheel, in one minute and 47 seconds. Crotty and Holbrook of Great Barrington, in a Jackson, came second, in two minutes.

In the race for touring cars, costing $4,000 or under, a Pierce Arrow, driven by J. M. Carey, was first in two minutes and seven seconds. The Stanleys had it their own way in the steam car event, G. P. Hunt, of Pittsfield, winning in 2:54.

SIXTEEN ENTRIES FOR FAIRMOUNT PARK RACE.

Philadelphia, Sept. 30.—Sixteen cars, which was the maximum number decided upon by the Quaker City Motor Club, have been entered for the 200-mile Founders' Week road race in Fairmount Park, Saturday, October 10. Several late comers had to be told that their entries could not be made. Here is the list:

Car.	Cylin-ders.	H.P.	Bore.	Stroke.	Entrant.	Driver.
Am. Locomotive	6	60	4 3-4	5 1-2	L. J. Bergdoll	Bergdoll
Maxwell	4	28	4 1-4	4 1-4	Maxwell-Briscoe Co.	Kelsey
Stoddard-Dayton	4	34.5	4 3-4	5	Hamilton Auto. Co.	Miller
Peerless	4	38	4 7-8	5 1-2	P. F. Du Pont.	Maucher
Palmer & Singer	6	60	4 3-4	5 1-2	C. A. Schroeder.	Wallace
Apperson	4	48.4	5 1-2	5	Phila. Auto. Co.	Davis
Welch	6	51	4 5-8	5	E. R. Bergdoll	Bergdoll
Studebaker	4	38.5	4 3-4	5 1-4	Studebaker Co.	Yerger
Locomobile	4	40	5	6	I. J. Morse	Tracy
Locomobile	4	40	5	6	I. J. Morse	Florida
Acme	6	45-50	4 5-8	5	Acme Motor Car Co.	Patchle
Chadwick	6	50	5	6	J. M. Munyon, Jr.	Harkins
Pennsylvania	4	38	4 3-4	5 1-4	Penna. Co.	Zengle
Lozier	4	45	5 1-4	5 1-4	Herm'n Brill	
Lozier	6	50	4 5-8	5 1-2	W. B. Herbert	
Pullman	4	40	4 15-16	5 1-4	York Motor Co.	La Roche

When the subject was first discussed among the members of the Quaker City Motor Club very little encouragement was given the leading spirits, as it was supposed that it would be impossible to secure permission from the municipal government and the Fairmount Park commissioners to conduct an automobile race over a course which included not only the driveways of the park, but also two blocks of city streets.

From the first Mayor Reyburn gave the project his hearty support, and the park commissioners were no less enthusiastic after being convinced that the race could be run safely.

WAVERLEY PLANT HAS NEW OWNERS.

Indianapolis, Ind., Sept. 28.—An important change in the automobile world took place when the Waverley department of the Pope Motor Car Company was sold to H. H. Rice, manager, and W. C. Johnson, assistant manager, of the Waverley department, representing a syndicate of Indianapolis capitalists, who purchased the property, merchandise, patents, good will, and business of the plant. The new concern will be known as the Waverly Company, and will devote its entire time to the manufacture of the Waverley electric carriages and trucks. These officers have been elected: President, W. B. Cooley; vice-president, H. H. Rice; treasurer, Carl von Hake; secretary, W. C. Johnson.

Herbert H. Rice entered the employ of the Pope Manufacturing Company in Boston in 1892, taking charge of the advertising department, where he wrote the first advertisement ever published for Colonel Pope's automobile factory. In 1895 he moved to Hartford with the sales department, and three years later took charge of the Providence branch. Since 1904 he has been at the head of the Waverley branch.

CORBIN WINNER OF SOUTHWEST RELIABILITY

KANSAS CITY, Mo., Sept. 26.—Victory in the Southwest reliability tour for the *Star* trophy perches on the banner of the Corbin, which made the entire eight-day tour of the Automobile Club of Kansas City with a perfect score. After two critical inspections at the finish, following a protest that the rear axle was sprung, the technical committee overruled all objections and awarded to Fletcher Cowherd, Jr., the entrant, the massive silver cup which is the trophy for which thirty-one cars contested.

A close second was a Rambler roadster, which finished with a score of 994. Eight other cars topped the 900-mark, and a few points against Corbin could have deprived it of the cup.

In the absence of observers there is a well-grounded suspicion against some of the high scores. It may be truthfully said, however, that the Corbin is open to no such criticism. For the first four days this car was almost constantly under the eye of THE AUTOMOBILE man, and for the other half of the tour, when perfect scores were few, the car was too closely watched by the other contestants to be able to break any rule without being detected. The refreshing fact stands out that not a voice has been lifted in depreciation of the Corbin. It made a clean fight, and finished under the rules with the best score. At the finish of the tour to-night the score stood:

No.		Miles.
13	CORBIN	1,000
31	RAMBLER	994
39	KNOX	989
16	CADILLAC	980
37	FRANKLIN	975
2	STEVENS-DURYEA	960
10	OVERLAND	952
3	PEERLESS	935
27	MAXWELL	932
21	CHALMERS-DETROIT	921
35	FORD	898
20	CHALMERS-DETROIT	896
15	PACKARD	886
9	STUDEBAKER	868
17	MAXWELL	723
7	POPE-HARTFORD	667
14	MAXWELL	479

The run really was a series of eight-day-tests, instead of an eight-day contest, as scheduled. At night the cars after checking passed into the hands of their drivers, and the garages can tell the tales of repairs, replacements, and rebuilding that went on sometimes until within an hour of the time to check out in the morning. This, however, did not count against the car, provided it could pass the night inspection at the time of checking in. As this inspection was not very rigid and did not go under the bonnets or past the grossly noticeable defects of a car, the penalties imposed under it were not very severe. The distance was almost 1,000 miles.

A Claim from the Brush Regarding Its Score.

DETROIT, MICH., Sept. 30.—Driver Huss, who drove the Brush runabout in the Kansas City endurance run, claims his score should be 777. After completing the run and being officially checked out, he states that he was informed that he had been disqualified because of his arrival at the Eureka control, Friday, three hours late. Huss could not find any checkers, and so informed the committee, which told him to continue according to schedule the following day, but later pronounced him disqualified through failure to check in. His lateness at Eureka was caused by losing his way, after going for help to assist a disabled car containing a woman and child. Including his Eureka penalties, his total loss of points aggregated only 223.

CAN RUN ENGINES IN COMMERCIAL SALON.

PARIS, Sept. 24.—Permission has been obtained from the Prefect of Police of the Paris district to allow gas engines to be run in the Grand Palais during the second Salon, to be held next December, for commercial automobiles only. In past years the commercial vehicle and machine tool section of the Paris salon has always been held in a temporary building in which it was possible to run the largest gas engines and have most of the machinery in motion without risk of fire. It was feared that permission would not be granted for this in the Grand Palais, an elegant structure dedicated to fine arts, and one of the most valuable buildings in the city. Special precautions will be taken, however, against the outbreak of fire.

The total number of exhibitors at the Paris Salon is 606, and the maximum space allowed each firm is fifty-three square feet. In the industrial section Americans will be represented by all the leading machine-tool makers; in the pleasure car show the firms having secured space are Ford, Buick, Rushmore, B. F. Goodrich Company, and Vacuum Oil Company.

MAY BE POSTPONED BECAUSE OF DUST.

INDIANAPOLIS, IND., Sept. 28.—Unless there is rain within the next forty-eight hours it is probable that the two days' reliability run scheduled for October 1-2 will be postponed until there is rain. The run, which is to be under the auspices of the Indianapolis Automobile Trade Association, is to be to French Lick and return.

HARTFORD CLUB LOSES AN ABLE WORKER.

HARTFORD, CONN., Sept. 28.—G. K. Dustin, secretary of the Automobile Club of Hartford and the Connecticut Automobile Association, has tendered his resignation to President Fuller, as he is leaving the State to take up his new duties in the position of chief engineer of the Susquehanna Railway, Light and Power Company. Mr. Dustin while in Hartford was superintendent of the Hartford Gas Works and also an enthusiastic worker in automobile circles, as the present condition of the local organization testifies. The new secretary has not yet been chosen, though several names have been suggested.

SAN FRANCISCO AGED GIVEN AN OUTING.

SAN FRANCISCO, Sept. 17.—Through courtesy of the California Women's Automobile Club, 150 aged inmates of San Francisco's public institutions were taken for an outing to-day in thirty-four donated automobiles. This is the second event of this kind that has taken place in San Francisco. Many of the occupants of the cars were helpless paralytics, or very frail. Dr. A. J. Minaker gave his careful attention to the scores of invalids. The cars assembled at the Ocean Beach, and proceeded along the boulevard to the residence of Mrs. Fremont, who had offered to Mrs. Frederick J. Linz, president of the club, refreshments for her guests.

ATTACK UPON INDIANA ROADS LAW.

INDIANAPOLIS, IND., Sept. 28.—An attack on the three-mile road law, enacted two years ago, is being made in the Indiana Legislature, which is now in special session in this city.

The law provides that upon the petition of fifty property owners in a county, a road not exceeding three miles in length shall be built, providing it connects two other improved roads. It is further provided that the expense shall be equally divided among all of the property owners in the county.

Recently a number of towns and small cities have taken action under the law to improve streets by paving them with brick and other materials. While the residents of these cities and towns have had to pay for country roads, the farmers are objecting toward sharing in the expense of improving city streets.

Mont Ventoux's New Record

By W. F. Bradley

Contestant Cutting a Corner a Bit Too Close on the Mont Ventoux Course.

AVIGNON, FRANCE, Sept. 22.—After standing for three years, the record for the Mont Ventoux has been broken. In September, 1905, Cagno covered the 13 miles on a Fiat in 19 minutes 13 seconds. This year Bablot started from the valley on a Grand Prix Brasier and climbed to the observatory, more than 6,000 feet above the sea level, in the record time of 19 minutes 8 4-5 seconds. Conditions were far from being at their best. On starting out the roads were so dry and hard that non-skids were not required; half way up there was a complete change, the mountain road being covered with a thin layer of melted snow that gave little hold for smooth tires. At this point Bablot had a lead of two minutes on the Fiat record, and would doubtless have maintained it had he been equipped with steel-studded tires. Under the unfavorable conditions, a little time was lost, but this did not prevent the Brasier clipping 4 1-5 seconds off the record.

Mont Ventoux is more than an ordinary hill climb, its length alone putting it in a class by itself. From the starting point to the observatory the distance is exactly 13.04 miles, with a gradient reaching as high as 20 per cent., certified by the government surveyors. Added to the difficulties of the grades are right angle and hairpin turns with rough surfaces overhanging precipices that are unprotected by either wall or hedge. There are difficulties of carburetion, too, the start being in the warm air of the southern valley, the finish around a snow-capped peak. Nevertheless, the 155-millimeter racer realized an average of close on 50 miles an hour.

In the stripped touring car class two minutes were clipped off the record by Deydier on a Cottin-Desgouttes, which roared up the mountain side in 22.2 3-5, the motor being a 140 millimeter four-cylinder.

Conditions were so unfavorable that several of the competitors requested that the climb should be postponed, and on the organizers refusing to accede, declined to start. No accident happened, however, the only scare being provided by Mottard on a La Buire, who swung round on himself at the St. Esteve bend and appeared for a second in danger of diving over the precipice.

Salons Straightaway Tests.

Most of those taking part in the Ventoux climb also figured in the straightaway tests at Salons two days previous. Here Bablot and his Brasier shared the honors with Alezy mounted on a 1906 Bayard-Clement six-cylinder racer. The Grand Prix Brasier covered the flying kilometer in 21 2-5 and in 21 4-5, giving an average of 21 3-5, equal to 103 1-2 miles an hour. The car was the one which the same driver handled at Dieppe, the additions for the occasion being larger sprockets, a V-shaped wind shield in front of the radiator, and a sheet metal covering for the space between the dashboard and the steering wheel.

Bayard-Clement Captured Most of the Honors.

The best time made by the six-cylinder Bayard-Clement on the flying kilometer was 22 1-5 seconds. Though both performances are good, they do not come near the record of Hemery on the eight-cylinder Darracq of Florida fame. In the touring car classes entries were plentiful, but categories were poorly filled, with the result that competition was not of the keenest, though it can be said the events were fairly interesting.

Alezy and his long, bonnetless six-cylinder Bayard-Clement, which first roared in 1906, made the fastest time on the five kilometers, standing start, his official time being 1 minute 52 seconds, equal to an average of 97 miles an hour. Bablot's Brasier occupied 1 minute 54 seconds to roar down the same poplar-lined band of perfect macadam, which was used as the course.

Alezy in Bayard-Clement Finishing 5-Kilometer Run at Salons.

Here Is Where the Storm Centre of the Great Vanderbilt Cup Race Will Be Located, and Speed in Plenty Will Be Seen.

VANDERBILT CUP CERTAIN TO RESULT IN NEW SPEED RECORDS

WHEN the list finally closes for the 1908 Vanderbilt Cup race, scheduled for October 24, it is a certainty that the entries will exceed the total in any previous event for this famous trophy. One thing is a certainty, and that is, that those that see this year's race are going to witness probably the limit obtainable in automobile speed, for the unlimited bore cars will extend themselves faster than ever before over the perfect surface of the Motor Parkway, which has been supplemented by adjoining roads placed in as good condition as is possible to make a State highway.

While the entries at first fees close in the mail of to-morrow morning, there will still be opportunity for the late comers to enter at double prices, though not more than twenty-five are likely to be permitted to start.

For the opening of the Motor Parkway itself, Saturday, October 10, a most generous entry has been made for the several sweepstakes, rolled into one as far as the onlookers are concerned, insuring the most pronounced kind of a success for the introduction of the first automobile speedway constructed.

On Tuesday Paul LaCroix nominated a Renault for the Vanderbilt Cup race, and the Matheson Motor Company named a Matheson. The day before had come a trio of entries of imported cars. W. K. Vanderbilt, Jr., designated a Mercedes; Foxhall P. Keene, another Mercedes, and Harry Payne Whitney, a Brasier. This, with the Graves' Mercedes and the Brokaw Isotta, raised the foreign division to six, and placed it only one behind in number with the American contingent, which on Tuesday was made up of two Knoxes, a Chadwick, an Acme, a Thomas, a Matheson and a Mora.

Wednesday's entries included a second Matheson and word from Bridgeport that the blanks for the two Locomobile racers had been placed in the mail. This gave a total of ten American and six foreign cars.

It now looks as though the struggle among the high-speed machines of the millionaire automobile racing contingent would be far from the least interesting feature of the great struggle.

Up to Saturday night a week before the date set for the closing of the entries for the Motor Parkway Sweepstakes, twenty-four paid nominations had been made in the five classes, into which the race is divided. The representation was as follows: Mitchell, four; Stoddard-Dayton, three; Knox, two; Chalmers-Detroit, two; Isotta-Fraschini, two; Pennsylvania, two; Palmer & Singer two; Garford, one; Allen-Kingston, one; Moon, one; Maxwell, one; Lancia, one; Hotchkiss, one; Gyroscope, one. The entrants, who manufacture or handle makes of several prices, had not given, as a rule, notice of their segregation of cars in the various price classes.

The sweepstakes promise to be by far the most novel and at the same time most exciting struggle yet conceived for automobiles. The idea practically combining five races in one, by starting the five fields at once, is a radical innovation that will probably become a feature of future stock car racing in this country. The large number of contestants will insure cars constantly racing and passing one another all along the course. The distances for the various classes differing, there will be added after the first three hours the excitement of successive finishes for the $1,000 prizes offered each prize division. The subdivisions of the sweepstakes are:

Motor Parkway sweepstakes, for cars selling above $4,000; distance 10 laps, or 250 miles.
Meadowbrook sweepstakes, for cars selling from $3,001 to $4,000; distance 10 laps, or 250 miles.
Garden City sweepstakes, for cars selling from $2,001 to $3,000; distance 8 laps, or 200 miles.
Jericho sweepstakes, for cars selling from $1,001 to $2,000; distance 6 laps, or 150 miles.
Nassau sweepstakes, for cars selling for $1,000 or under; distance 4 laps, or 100 miles.

Spectators on the homestretch will be treated to a noteworthy innovation in the establishment of a depressed official supply station stretching for 300 feet in front of the grandstand. It will take the form of a pit 10 feet wide and 5 feet deep, and will

Where the Long Island Motor Parkway Passes Under the Main Highway Near Central Park.

be reached by a switch from the main course. Here will be kept tires, oil, water, and gasoline. The heads of the mechanics will be visible above the edges of the pit. Not only will the passing of supplies and filling of tanks be seen, but the interesting operation of the quick-changing of tires also. Working space in this pit will be sold to entrants at $10 each. They will be compelled to keep their gasoline in sealed five-gallon cans and hand them to the drivers in that shape. No gasoline will be permitted to be fed under pressure, and no smoking allowed.

There will be another official supply station established on the backstretch somewhere along the old Jericho turnpike. It will not, however, be depressed. The supply men will be separated, though, from the course by a railing. In neither of the races can supplies be taken on elsewhere than at these official stations. No tires can be replaced except at these stations, except those whose tires have been thrown between stations and an extra tire has been carried on the car.

A novelty is to be tried in connection with the Motor Parkway Sweepstakes in the admission of touring cars to the cement stretch with the privilege of parking along the course. They will only be barred from the outside of curves and bridge crossings where there is danger of racing cars plunging into the crowd. Touring cars seeking these parking advantages will be admitted to the cement stretch between daylight and 8:30 A. M. They can enter by the toll lodge at Meadowbrook, or by either of the toll lodges at Bethpage and Massapequa. An admission fee of $10 will be charged. Tickets may be obtained from the uniformed toll-keepers, or in advance at the offices of the Vanderbilt Cup Commission, No. 437 Fifth avenue, New York City.

The grandstand, which is being built on one of the main stretches of the cement parkway, is nearly completed. It will seat 5,000 spectators. It is divided into nine sections, each section containing 34 boxes, or 306 in all. These boxes are along the edge of the course. Behind them rise tiers of seats to the roof. The latter will afford protection against the sun or rain. Should there be rain, by the way, there will be no necessity for a let-up of speed along the homestretch, as the cement is broomed to make skidding impossible.

Three-quarters of a mile on the old Jericho turnpike is being resurfaced. The dangerous "Flatiron turn" at the Jericho turnpike and the Woodbury road is being rounded for safety. A new road is also being built across Hempstead Plains to the beginning of the parkway. It is three-quarters of a mile in length and eighteen feet in width. Twenty-two thousand gallons of oil are to be spread on the fourteen miles of county and State roads included in the Vanderbilt circuit.

Equipment houses are beginning to offer big money to drivers. The Michelin Tire Company, for instance, will give $1,000 to first, $750 to second, and $500 to third in the Vanderbilt, providing the cars winning those places are shod with Michelins.

Lautenschlager Victim of Accident.

STUTTGART, Sept. 25.—Lautenschlager, the winner of the Grand Prix of the Automobile Club of France, has met with an accident which may prevent him racing again this season. While testing the 155-millimeter racer which he was to have driven in the Vanderbilt Cup race, the Mercedes driver burst a tire on one of the turns of the factory track and came into violent collision with a wall. Under the blow Lautenschlager had his wrist broken and most of the bones of his hand laid bare. A complete rest of one month has been ordered by the doctors, but it is doubtful if the Mercedes tester will be able to take the wheel of a racing car at the end of that time.

Emil Stricker, Mercedes Pilot, En Route.

PARIS, Sept. 24.—Emile Stricker, who has been engaged by Robert Graves to drive the Jenatzy Mercedes in the Vanderbilt Cup race, has sailed for New York. Stricker, who was born in Germany thirty-one years ago, went to the United States at the age of fifteen, and later became a naturalized American, has figured in the last two French Grand Prix races. In the race at Dieppe last July, where he piloted a six-cylinder Porthos car, he was put out of the running on the last round, while in a fairly good position, through the collapse of his road wheels on a straightaway. Stricker is well known in New York City, having been with the Mercedes company when they first imported cars in 1898, and later with the New York house of the Rochet-Schneider Company.

ENTRIES FOR SAVANNAH'S GRAND PRIZE.

The American end of the Grand Prize race was given a boost on Tuesday by the announcement that Harry A. Lozier had entered a Lozier. The noteworthy feature of the nomination was the fact that the machine in question is not a stock car, but a racing machine out and out, which was begun at the factory in June, and is said to have been so far completed as to have for some time been subjected to tuning up on the road. This raised the American contingent of candidates to four, a Locomotive, an Acme, and a B. L. M. having previously been formally entered.

The foreign contingent had a day or two earlier been strengthened by the entry by the Kaiserlicher Club of Germany of two Mercedes, one to be driven by Salzer and the other by Poegge. Previous foreign entries were three Fiats and two Benz.

The same day the announcement was made of the entry of another Buick for the light car race at Savannah, raising the number of candidates to ten, the other nominations being three Maxwells, three De Dions, and two Gyroscopes.

FOURTEEN CARS IN BRIGHTON 24-HOUR.

For its second 24-hour race at Brighton Beach, which takes place on Friday and Saturday of this week, the Motor Racing Association has secured 14 entries, with a possibility of the number being increased by two more when the starter gives his getaway signal at 8 o'clock on Friday night. Of the contenders in the last race, the Lozier "six" and "four," the Stearns, the Fiat, the Allen-Kingston, the Simplex, the Acme, and the Garford have been again entered. Harry C. Houpt has nominated a six-cylinder and a four-cylinder Thomas. Paul LaCroix, whose Renault was wrecked by an accident in the last race, has nominated two Renaults. Walter C. Allen has announced that the drivers of the Allen-Kingston will be Crane, Rippigill, and Tod Sloan, the ex-jockey. Patschke will take Strang's seat on the Acme. An entirely new entry is the Cleveland. Louis Chevrolet, who was a star track driver in the days of Morris Park and Yonkers, is named as its chief driver, with Miller and McCann as alternates. A Zust has been entered.

Short races are scheduled to be run to-morrow afternoon.

ITALY TO GIVE BIG CASH PRIZES IN 1909.

BOLOGNA, ITALY, Sept. 25.—Satisfied with the excellent results of the races just held, the Automobile Club of Bologna will next year hold a race under the prevailing Grand Prix regulations—whatever they may be—and will offer special attractions in the form of $40,000 cash prizes. The decision was arrived at at the closing banquet of the recent meet, when a subscription list was opened for next year's event. First prize will be $10,000, second, third and fourth arrivals being awarded smaller amounts. The amount promised already reaches $6,000. It had been understood that no race should be held in Italy next year, the second edition of the Grand Prix being run on the Belgian Ardennes course. Evidently this agreement will not be adhered to.

MANN LEAVES HOTCHKISS FOR DELAUNAY.

PARIS, Sept. 25.—J. J. Mann, European consulting engineer of the American Automobile Association racing board, who has been prominently connected with the Hotchkiss Company since 1902, left that firm a few months ago, and since then has been taking a rest, demanded by the state of his health. Mr. Mann has just taken up an engagement with the automobile department of the Delaunay-Belleville Company, at St. Denis, near Paris, and will have full charge of the foreign selling branches. Mr. Mann will shortly visit America.

HORSE-POWER RATINGS OF AUTOMOBILE MOTORS*

By THOS. J. FAY, President Society of Automobile Engineers.

INDIRECTLY, a torque curve is the equivalent of an indicator card. However, if the card is available, it becomes possible to note why a motor fails to perform up to the normal. If the card can be had, the formula will read as follows:

$$H.P. = \frac{PLAN}{33{,}000}$$

in which

$H.P.$ = the indicated horse-power;
P = the mean effective pressure;
L = the length of the power stroke in feet;
A = the area of the piston in square inches;
N = the number of the power strokes per minute;

In a single-cylinder motor, of the four-cycle type, there will be one power stroke for every two revolutions, hence, if the motor is of the four-cylinder type, there will be one power stroke for every revolution. The number of the power strokes then may be found as follows, for any number of cylinders in a four-cycle motor:

$$N = \frac{C}{4} \times S \text{ in which}$$

C = the number of cylinders;
S = angular velocity of the crankshaft in r.p.m.

In this formula the compression is taken into account, in that the mean effective pressure P, involves the same element. It will be observed, however, that the result is in indicated horse power, instead of actual horse power. The losses in the motor are not taken into account in this case and since they are of considerable moment, besides being difficult to ascertain in the absence of the brake test the method does not spell finality. Up to the present, in this discussion, the idea of predicting what the rating of a gasoline motor should be in horse power, assuming a four-cycle motor, was uppermost, but it cannot be claimed that the methods disclosed availed much by way of accuracy.

If the four-cycle motor will not lend itself to the problem, it is not believed the two-cycle motor will stand for any prognostication at all, as the variables in the latter are much more difficult to arrange. In the two-cycle motor, the compression (cold) means very little, because it is impossible to say to what extent the mixture is contaminated as a result of the speed.

Even in the four-cycle motor, the mixture is far from free of burnt residue, though the conditions are extremely good as compared with the two-cycle motor. If a formula cannot be devised that will serve for the four-cycle motor, it will be a waste of time to try to devise one for the two-cycle type. In the main, it is not essential to success to predetermine the exact power, because, if experience dictates that a certain size of motor will serve a certain purpose, it becomes a matter of the construction of the motor to meet the conditions to be satisfied.

If the ability of a motor cannot be predetermined with satisfying certainty, the natural question is: How can this ability be established in actual practice? In fixing upon this, the question will also arise as to wbether it is to be the highest instantaneous value, or the average valve, involving enough time to fix upon the latter with certainty. The Prony brake affords a means of determining the instantaneous value of the power, but it is not believed this method serves if a considerable time factor intervenes, due to the difficulty involved in disposing of the heat into which the energy is converted. A superior means, affording a long time run, involves a dynamo and the requisite instruments. Certainly there is a material difference as between the power of a motor as it is observed by means of a Prony brake, and the power average of fixed time readings for a long interval of time.

The instantaneous brake readings are likely to be influenced by the flywheel effect, and it is possible to so adjust the carbureter as to produce results that cannot be maintained for a long time. It is also possible to so time the spark as to influence the readings in favor of a high rating, if it is not necessary to maintain that adjustment for a long time. The cooling question is also one that has a bearing upon the matter, the power of a motor being affected by the temperature of the motor. If a motor is quite small, and the Prony brake is very well designed, it may be that a considerable degrees of success can be realized, but the best that the Prony brake affords is not nearly so good as the results following the use of the electrical system of testing.

While the various instruments of precision, and the general equipment used in testing, will be treated in detail in a special chapter, it may be well here to note that the Prony brake is of the absorption dynamometer genera, and depends for its success upon its ability to absorb and dissipate the heat equivalent of the mechanical effort of the motor. This heat absorption, and especially the after dissipation, is generally attended with considerable difficulty, since if the temperature increases over much, the brake shoes do not behave in a manner to admit of steady readings.

Some Prony Brake Data.

The Prony brake consists essentially of a set of brake shoes, of any suitable design, attached to a lever arm (usually counter balanced), with a means of adjusting the tension of the brake shoes and a suitable scale for weighing in pounds the force exerted at the end of the lever arm.

The customary length of the lever arm is 5 feet 3 inches for the following reason:

$$\text{H. P.} = \frac{SP}{1{,}000}$$, in which S = angular velocity of the crankshaft, if the brake shoes are attached to a drum that rotates at the same speed as the crankshaft, usually the case; P = the pull in pounds at the radius of the lever arm, usually 5 feet 3 inches, as before stated. If the length of the lever arm differs from that given, the formula must be altered to suit. For any other length, the formula becomes:

$$\text{H. P.} = \frac{2RSP}{33{,}000}$$, in which the symbols are of the same values as before given.

The brake drum should preferably be of the same diameter as the flywheel, on the ground that cast iron (the usual material) will not be safe to use of a greater diameter, provided the flywheel is of the maximum allowable for cast iron. At all events, it will not be desirable to use a cast-iron brake drum of a diameter so great as to fix the peripheral velocity in excess of about one mile per minute, at the normal speed of the motor. Even this would be a high value in some cases, involving motors with relatively large valves. The drum must be water-cooled, and for good results it is desirable to maintain the water at a constant temperature, which can only be accomplished by running water through the jacket of the drum. It might also be well worth while to have the brake shoes water-jacketed.

The brake shoes to serve the purpose have to be faced with some material that will have a nearly constant coefficient of friction, notwithstanding the severe changes in temperature, which is a matter of some concern, since but few materials seem to serve with any degree of satisfaction. Cast-iron brake shoes with cork inserts would probably come nearer doing the work than any other means. Certainly leather, or any other material that carbonizes, would not serve at all. With the cork inserts in the shoes, the question of cast iron to the same would not come up, and for a given diameter (fixed by considerations of safety) of the brake drum, the face of the shoes (slightly less than the face of the drum) would be as follows:

*Continued from page 430 of "The Automobile," September 24.

$W = \frac{350 \text{ by } H.P.}{V}$, in which W = the width of the shoes in inches; $H.P.$ = the probable maximum horsepower of the motor; V = the peripheral velocity of the brake drum in feet per minute, which for convenience might be fixed at 5,000 feet.

For a 50-horsepower motor with a 22-inch brake drum, the face would be as follows: $W = \frac{350 \text{ by } 50}{5{,}000} = 3.54$ inches; the drum might well be four inches, thus affording a little margin.

The above will only hold true if cork inserts are provided in the brake shoes and with the water maintained at a fairly constant temperature. The scales might all be of the beam type, of the better grade, with the arm graduated to quarter pounds, or finer. The means for putting tension on the brake shoes should be quick-acting and operate by minute increments. Indeed, it is in connection with this detail of the design that most Prony brakes become so very troublesome as to debar their use, unless for the most crude and unreliable tests. With a crude method of altering the pressure, the shoes chatter and the scale readings become a mere guess.

The speed in r.p.m. cannot be taken by means of an ordinary speed counter, a calibrated tachometer being absolutely necessary, the finer (dead beat) types giving instantaneous values.

Safety is a matter so much to be kept in the mind's eye that it will not be out of place to call attention to the dangers to be encountered in the use of the Prony brake. In a cast iron wheel, no matter what the area of the section of the rim, the centrifugal force, resulting from the speed, will set up a tension in the rim independent of the area of the section.

Speed Should Be Kept Within Bounds.

In testing a motor, while the normal speed may be quite low, the chances of the "free" speed being very much higher are very great. The normal speed of a motor might be, say, 1,000 r.p.m., while its "free" speed might be 3,000 r.p.m. This would be a little unusual, since it seems to be the case, in general, that the best power of a motor lies somewhere near two-thirds of its free speed. At all events, if cast iron is the material of the brake drum, and it is designed for 5,000 feet per minute at the normal speed of the motor, it becomes necessary to consider what would be the result of three times that peripheral velocity.

For cast iron the tension in the rim section would be: $T = \frac{V^2}{10}$, in which V^2 = the square of the peripheral velocity in feet per second; T = the tension in pounds per square inch.

For the case in point: $T = \frac{250^2}{10} = \frac{62{,}500}{10} = 6.250$ pounds per square in. $V = \frac{15{,}000}{60} = 250$ feet per second from 15,000 feet per minute.

Cast iron is a product upon which no reliance can be put beyond a certain point. It matters little that tests showing as high as 35,000 pounds per square inch (tensile strength) can be cited; it is not safe to accept over 18,000 pounds per square inch, nor even this figure in a case of this sort, unless the castings are very good indeed from well-executed designs and in accord with the characteristics of cast iron. Even so, the factor of safety is not quite what it ought to be, while on the other hand, it is not well to reduce the diameter of the brake drum below the possible maximum, considering cast iron. If steel castings are adopted instead, then the diameter might well be at least 24 inches, on the ground of a better performance of the brake.

As it is, the factor of safety is barely three to one, and it is true also that no account has been taken of the fact that the brake drum must survive under severe conditions of service, due to variable pressures and sudden changes in temperature, for, even if the water-jacket is well devised and the attendants look well to the details of the task, the time will come when the drum will be allowed to heat up to the maximum for the work. Perfectly uniform walls of no great thickness will best serve the purpose, in the case of the brake drum, for then the metal will be of the greatest unit strength, defects will not be so difficult to discover, and the heat will be the more readily disposed of. In designs of this sort, perfect symmetry is of the greatest importance, and at such high speeds the drums must be statically and kinetically balanced, the radii must be liberal, and thick sections of metal should not be directly attached to thin sections.

Some Primary Considerations.

Before motors can be tested, they must be designed and constructed, while the test equipment must also be devised on a basis of the probable requirements. Leaving entirely aside the question of the extent to which precedent may be followed, principles must be uppermost, unless a "Chinese copy" of some motor already built and of known characteristics is the sole product. The motor must be designed specifically for the car it is to actuate. If it is heavy, the car will be heavy in two ways; that is, for two reasons, which may be set down as follows:

(a) The heavy motor will add weight to the car.

(b) The chassis framing must be made rigid and strong in proportion to counteract the ills of the extra weight in the motor.

The power of the motor will be in proportion to the square of the diameter of the piston (bore of the cylinders), will bear some relation to the number of the cylinders, and will, furthermore, be influenced by the stroke. The power requirement is dependent upon the weight of the car, the attainable speed and the wind resistance, which becomes a factor, if the speed is above 20 miles per hour. There are numerous other influences besides, as the road, tires, and the details of design of the car as a whole. The right motor for the purpose then will be the one as follows:

(I) Adequate in point of power for the intended service.

(II) Of the maximum "weight efficiency," without sacrificing stability.

(III) Of the utmost thermal efficiency, consistent with the above considerations.

To have the motor as light as possible, without considering the cost of maintenance, would be as much of an error as to design for the highest possible thermal efficiency without respect for the weight efficiency. It is unfortunate that the thermal and the weight efficiencies are not coincident.

The stroke has an important influence on the two efficiencies, barring the question of compression, and is the topmost factor of control. The short stroke motor is the lightest in weight, while the long stroke motor will show better in point of thermal efficiency. Where to draw the line is a matter that practice has never settled, because in practice the stroke has receded from 12 to 4 inches, and now that it is very short, the tendency is again to increase it. The cost of fuel renders it desirable either to bring about a reduction in its price or to strive for a higher thermal efficiency.

For some years the stroke has held between 7 and 4 inches with but very few over 6 inches. The 1909 cars will be largely of the very short stroke type, mostly with four cylinders and rather high speed, with quite large valves in proportion and a fairly high compression, as automobile motors go. Motors so designed will be light, and the power will be that for a high weight efficiency rather than for a high thermal efficiency. Abroad there is a recession to the lengthened stroke, in view of the hankering for a higher thermal efficiency, since it is in France, Germany and the other Continental countries that fuel is more expensive.

Stroke Length as Influenced by Fuel Cost.

To what extent it is desirable to lengthen the stroke to placate the buyer of the fuel is a matter not so acute in America, because in this country fuel is not so expensive, while on the other hand the roads are not so good. This latter consideration is one of some import, for with inferior roads high weight efficiency becomes the matter of moment. High thermal efficiency, at the expense of weight, is something to consider, if the roads are good. In other words, the amount of fuel used, if the roads are not so good, will be least in the case of the lighter automobile of lower thermal efficiency.

To what extent the stroke is responsible for increased weight,

on the one hand, and increased thermal efficiency on the other hand, is a matter not so easy to dispose of. That the weight will be materially less if the stroke is short goes without saying. The extent to which the short stroke decreases the thermal efficiency, however, is not a matter to be disposed of offhand. Not considering the carbureter, it will be possible to indicate the lay of the land, as the stroke *per se* tends to influence the situation. The curve, Fig. 1, shows the increase in horsepower attending an increase in stroke, with a fixed bore and all other conditions as nearly constant as possible. This curve cannot possibly be regarded as representing an abstract situation, apropos of all motors and of the widest range of cylinder dimensions. It is strictly limited to motors of bores less than 8 inches and over 4 inches. These limits must be applied, because numerous conditions will render themselves manifest if the bore is increased very much, while very small motors are a law unto themselves.

From the curve it would appear as if the very short stroke motors would scarcely afford the ability necessary to render their construction desirable, or may we say profitable. Short stroke motors deliver power on a high plane from the weight efficiency point of view, and it is only relatively that they look so discouraging. To illustrate this situation, it will be necessary to give evidence by way of a weight efficiency curve under as nearly the same general conditions as the author can, in view of the difficulty involved, due to the lack of uniformity of the data extant on this rather important matter.

Results Shown by Power-Weight Curves.

Fig. 2 shows the decrease of weight efficiency, as the stroke is increased, considering a constant bore and a constant piston speed. This is given merely to show the trend, and is quite as accurate as it can be under the conditions governing the comparison of these two factors.

The conclusion to be reached is that the power will be doubled if the stroke is doubled (starting with the shortest stroke in vogue), while the weight efficiency will change to 120 points for the long stroke as compared with 100 points for the short stroke. Thus it would seem to be a good thing to increase the stroke, especially if we look no further. But the increase in points on the weight efficiency scale means an increase in the actual weight of the motor of 100 per cent. This is vastly more than would obtain for double the power, if that increase were to be effected by means of an increase in bore, rather than by doubling the stroke. Indeed, double the power might result with an increase of 50 per cent in weight by changing the bore and sticking to the short stroke. Obviously, the long stroke is not so valuable, if the car is to be light, nor will the increased thermal efficiency be of such value as to make up for the fuel cost of "toting" the increased weight over the average American roadway.

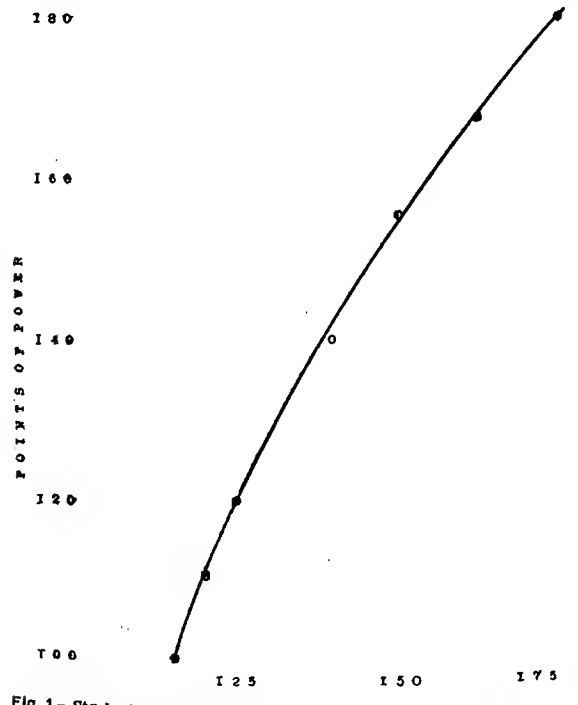

Fig. 1.—Stroke in millimeters for a four-cylinder four-cycle motor bore equals shortest stroke.

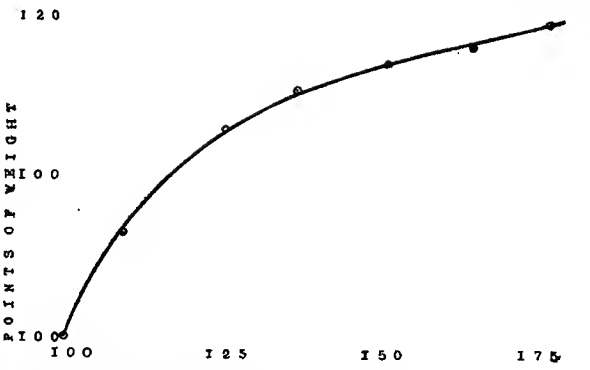

Fig. 2.—Stroke in millimeters for a four-cylinder four-cycle motor bore equals shortest stroke.

It is true that the thermal efficiency will be higher in the case of the longer stroke motor, because the scavenging is more complete, and the time per phase of each cycle is greater, the number of oscillations of the mixture in the intake is less, since for a given piston speed the number of changes in direction are reduced. But there are other conditions besides, as for illustration, the timing is more exact, the lag of the spark being considerably reduced, if the stroke is considerably longer. The valve action is sharper, more pronounced, and losses in the passageways are less noticeable. No mention has been made of the differences in mechanical losses, the inertia component of the reciprocating mass being more pronounced, if the stroke is short, the piston speed being the same for both. This latter consideration will be subject to a correction, if the long stroke motor is designed in such a way as to have massive reciprocating members; very often the case.

It cannot be claimed that the long stroke motor has an advantage on any count involving the initial compression, because it is possible to show that the short stroke motor is amenable to whatever treatment will afford benefits by way of adjusting the compression. It will avail nothing to discuss the question of increasing the piston travel in the long stroke motor, because it is the short stroke motor that best withstands such treatment. Nor is it due to the more complete expansion in the long stroke motor that the increase in power is to be expected. The increase in power is largely due to the more nearly constant compression and the more nearly "flat top" curve of torque. In the short stroke motor the "cold compression" is quite as high as in the motor of the longer stroke, and there is no reason why the initial compression should be less in one than it is in the other.

At the higher speed of the short stroke motor the torque falls off, and it is not so to the same extent in the long stroke motor. It is principally in this regard that the short stroke motor offends, and on this account more than for any other reason, increasing the stroke increases the power.

In spite of all these more or less obvious defects of the short stroke motor, it is very satisfactory in operation, and in more ways than one it has the advantage of a longer stroke. It is something to keep the weight down and more to establish a low center of gravity; it is also desirable to be able to cast the cylinders with the least number of "wasters."

(To be Continued.)

USEFUL THINGS FOR THE AUTOIST TO KNOW

OVER-HEATING of the engine, when not traced to poor circulation, is almost always caused by too much gasoline. There are, however, many possible causes of over rich mixture, some of which on the face of them might seen rather to be causes of lean mixture rather than rich. Prominent among these latter is too low a gasoline level in the float chamber due to the float valve closing too soon. The immediate effect of this is to make the mixture too lean at starting and at low speeds. Starting is therefore difficult, and if the auxiliary air valve begins to open at the usual motor speed the mixture will again be much too lean. These symptoms, however, unless properly interpreted will probably lead the owner to increase the gasoline supply, or to adjust the spring tension of the auxiliary valve so that the latter will not open until quite high speed is attained. In other words, he adjusts to give a suitable mixture at one speed and at other speeds the mixture is extravagantly over rich. It is well not to be too easily satisfied with the carbureter's performance, as it may be found that one fault such as the above has been imperfectly offset by another fault in the other direction instead of the correct adjustment being made wbere the fault really lies. A good carbureter will give a sensibly correct mixture at all speeds within the ordinary range of tbe engine. If is fails to do this the thing to do is to investigate until the trouble is found.

Keeping the Lens Mirrors Clean.

Few owners of cars, even those who drive frequently at night, appreciate the importance of keeping the lens mirrors and front glasses clean. A greasy or dingy surface such as follows one or two evenings' driving absorbs a considerable percentage of the light from tbe flame. By far the best and handiest thing to clean the lens mirrors is a mixture of equal parts alcohol and water. Denatured alcohol answers the purpose perfectly well. Pure alcohol evaporates so quickly that it leaves the greasy film pretty much as it was, whereas a 50 per cent solution evaporates more slowly and gives time to wipe the glass clean. It would be an excellent idea for every garage to keep a bottle of this solution and some clean rags always on hand. While on the subject of lamps it is worth mentioning that all gas tubing from a generator should slope either downward or away from the generator, and there should be provision for draining it at its lowest point, since there is a gradual condensation of water in the piping which, if it collects in pockets, results in objectionable flickering.

Changing Carbureter Spray Jet Size.

Occasionally a carbureter is found to be too large for the engine or to have too large a spray orifice. The advice has been given in such a case to reduce the size of the spray orifice by lightly pening the top of it with a hammer. This is counsel of doubtful value, even if the hole be afterward reamed true, since it is manifest that the burr formed in the top of the orifice cannot possibly be deep enough to be at all regular in its form. It will almost inevitably throw a jet slantwise instead of straight, and this jet failing to strike the main part of the air stream will be only partly atomized, with resulting misfiring and general bad behavior, especially at low speeds. If a new nozzle of smaller size cannot be substituted, the best thing to do in case there is no needle valve to adjust the flow of gasoline to the jet is probably to warm the ingoing air as much as possible, in order to make evaporation by temperature take the place of atomizing due to the air's velocity.

Large Oil Gun a Valuable Adjunct.

A handy appliance for the garage and even for the private owner is a large quick action oil gun, which is easily made from an old bicycle pump by plugging up the outlet and drilling and tapping the bottom plate for a nozzle. The bottom plate can be cut down to the diameter of the pump barrel in case it has an extension to be held by the foot when pumping. Autoists will find such an oil gun as the above handy in many ways, as for quick filling of lubricators and scattered oil cups. It is very convenient also for sucking out the oil from the gearcase when a fresh supply is to be put in. This oil is usually too stiff to drain out, and as it is too full of steel chips to be allowed to stay in the gearcase, it must be removed in some manner. Obviously for such use the nozzle of the oil gun should be short and fairly large to permit the thick oil to enter.

Quickly Locates a Knock.

Tracing a knock is sometimes a puzzling job. It may be in one of tbe main bearings of the engine, in the camshaft bearings, in a loose valve lifter, in a loose camshaft gear key, in a loose pump or magneto drive coupling, an unsuspected loose bolt between two parts supposed to be fast, or in any of a dozen or score of other unsuspected places. A valuable aid in locating a mysterious knock is a flexible speaking tube such as is used with phonographs. One end of such a tube can be held to the ear and the other moved about from point to point until the exact spot is found where the noise is loudest. Another aid is a light bar of iron, one end of which is pressed against the part where the knock is suspected and the other touched to the forehead or the teeth, when the sound is clearly transmitted.

Handy Piston Head Scrapers.

In most engines the piston heads can be scraped clean of carbon without removing the pistons from the cylinders by means of specially formed scrapers introduced through the opening over the valves, or through the spark plug holes when the latter are horizontal. The form and size of scraper will depend on the particular engine, but almost any suitable form may be made from 5-16-inch steel tubing about 12 inches long having the ends hammered flat and turned over at right angles in a vise. The ends are then filed straight and sharp, and the shank of the scraper may be bent to right or left, if necessary, or left straight. Frequently two scrapers will be needed in order to use both right and left hand bends. The advantage of tubing for this purpose is that no blacksmith work is necessary.

Draining Gear Box and Rear Axle.

It is a familiar fact that the gearbox requires to be periodically emptied of oil and the accumulated metal grit washed out before fresh oil is supplied. The same is true of the rear live axle casing, except that the gears in the axle do not clash and therefore do not wear out as fast as the change speed gears. At least once in a season the oil in the rear axle should be drained out, a liberal supply of kerosene introduced, and the axle jacked up while the engine is run to agitate the oil and wash out the differential, etc.

Care of the Tire Pump Leather.

The proper unguent for the cupped leather washer of the tire pump piston is vaseline. Oil is too thin and it tends to work into the rubber hose, and even into the tire itself if too much is used. Vaseline, on the other hand, clings to the leather and lasts a considerable time. If the leather becomes dry it does not hold air well and pumping to high pressures becomes impossible, while the labor of pumping even to low pressure is greatly increased.

How to Get Rid of the Squeaks.

It is very annoying to have the car rattle and squeak whenever it goes over a little irregularity in the road, and it is also bad for the car. Each squeak means friction in the spring hangers, radius rods, or brake connections, or between the spring leaves, which, if not corrected, will soon cause a permanent looseness. Liberal use of the oil can is the obvious remedy. A light-running and noiseless car is always the sign of a good driver who takes pride in his work.

MIXED FUELS FOR AUTOMOBILE ENGINES

By THOMAS L. WHITE.

IN considering the question of mixed fuels, it is well to bear in mind that there is no such thing as an ideal fuel to serve the purpose of a standard. Nor, for the matter of tbat is it altogether correct to say that any one fuel is intrinsically superior to any other. What is really implied in such a statement is that for use in the standard motor, which is an instrument designed to burn gasoline, fuels naturally grade themselves in a descending scale. On such a list crude oil would hardly find a place at all, yet given a motor designed for burning it, this fuel can hardly be surpassed. To quote from an address on "Fuels for Automobiles," recently presented by Dr. Fritz Warschauer to the Association of German Chemists at Berlin: "As the burner of a kerosene lamp is formed differently from the burner of an alcohol lamp; as the construction of a gas burner is radically different from that of an acetylene burner; so also the combustion motor must be especially adapted to the peculiar properties of the fuel used." This necessary adaptation may range all the way from the total reconstruction of the motor in its more basic features to a few easily made adjustments in the carbureter, and it may be taken that the tendency of "the attempts which are being made everywhere to produce a suitable automobile fuel" is to conserve by suitable blending the structural integrity of the automobile motor as we have it to-day.

Apart from the possibility of an increase in the fuel resources of the world due to some revolutionary discovery, the ingredients in any mixed fuel for automobile use must be confined to the following list, in which, for completeness, gasoline is included:

GASOLINE.
Averags composition, C=84, H=16.
Source, petroleum.
Boiling point, 50° to 150° Cent.
Specific gravity, .680 to .720.
Calorific value, 19,000 B. T. U.
Latent heat, small.

BENZINE.
Average composition, C=92, H=8.
Source, coal tar.
Boiling point, 80° Cent.
Freezing point, 5° Cent.
Specific gravity, .899.
Calorific value, 19,000 B. T. U.
Latent heat, small.

ALCOHOL.
Averags composition, C=32, H=8, O=35.
Source, vegetable matter, principally corn, beets, potatoes, sugar cane.
Boiling point, 70° Cent.
Specific gravity, .806.
Calorific value, 12,600 B. T. U.
Latent heat, considerable.

TAR BENZOL.
Averags composition, C=92, H=8.
Source a by-product in the manufacture of coke.
Boiling point, 80° to 120° Cent.
Specific gravity, .895.
Calorific value, 19,000 B. T. U.
Latent heat, small.

KEROSENE.
Average composition, C=85, H=15.
Source, petroleum.
Boiling point, 150° to 300° Cent.
Specific gravity, .800 to .825.
Calorific value, 19,000 B. T. U.
Latent heat, considerable.

MOTOR SPIRIT, NAPHTHA, BENZOLINE, BENZINE.
Average composition, C=85, H=15.
Source, petroleum and shale.
Boiling point, 60° to 160° Cent.
Specific gravity, .750.
Calorific value, 19,000 B. T. U.
Latent heat, appreciable.

METHYL ALCOHOL, WOOD SPIRIT, NAPHTHA.
Averags composition, C=38, H=12, O=50.
Source, the distillation of wood.
Boiling point, 66° Cent.
Specific gravity, .812.
Calorific value, 9,600 B. T. U.
Latent heat, appreciable.

ACETYLENE ETHENE.
Averags composition, C=92, H=8.
Calorific value, 25,000 B. T. U.

This last named gas is an endothermic compound, which means that, independently of its energy as a fuel, it is capable of decomposing with the evolution of heat when submitted to the action of great pressure or heat or both.

Such being the chief materials at the service of the blender, what are the principles which determine the nature of the results which we can hope to attain? The broad guide to work by is, of course, that of averages. By it the calorific value of a pound of mixed fuel can be calculated once the calorific values of its constituents and the proportions in which they are present are known. The latent heat of a blend can be figured in the same way, and within limits its behavior in passing under the action of heat from the liquid to the gaseous state. It is when we come to the actual phenomenon of combustion in the motor that the relation of what should happen to what does happen ceases to be entirely a matter of averages.

The useful work which can be extracted from a given fuel by a heat engine does not merely depend on the calorific energy of that fuel, that is, on the gross number of heat units which are liberated by the combustion of a pound of it, but also on the manner of their liberation. Thus, to take one point of importance which enters into the question of the efficiency of a motor, it makes a great deal of difference whether combustion is complete during the early part of the power stroke or is continuous during the whole expansion. Consequently, when we are considering the combustion of a given fuel in a given motor, the consumption per horsepower hour depends on two factors, one of which may be described as quantitative, and the other as functional. When two fuels are blended to make a third it is the functional quality of the mixture which evades the rules of averages. To cite an extreme illustration, although water would generally be regarded as the antithesis of a fuel, having no calorific value whatever, the addition of a small percentage to pure alcohol actually increases its thermal efficiency in the motor. And generally, when a blend is made of two fuels the effect of each on the manner in which the other liberates its energy is a factor in the thermal efficiency which cannot be calculated and which must therefore be determined empirically. This does not pretend to say that there is no room for intelligent anticipation, but simply that exact deduction is not possible.

Confusion Regarding Addition of Various Fuels.

It is a common idea that the maximum power of a motor can be increased by the addition to the fuel used of another of a higher calorific value. This belief is not borne out by facts. It is a matter of calculation, which can easily be verified, that the percentage increase in the calorific value of the blend due to the added ingredient is almost exactly in the inverse proportion of the percentage decrease of the weight of the blend which can be consumed in one stroke of the motor. Or, to put the matter another way, it appears to be a fact for all known fuels, and therefore for mixtures as well, that the calorific value of a given fuel and the amount of air necessary to burn one pound of it have a ratio which for practical purposes may be regarded as constant. There is no allowance made in this statement for variation in thermal efficiency nor for any endothermic energy which may be liberated in the motor. In the light of the fact that the specific power of a motor is thus virtually constant, it is curious to find Dr. Warschauer stating, "The addition of benzol materially increases both the inflammability and the calorific value of alcohol. The motor output, therefore, increases while the fuel consumption is reduced." If the output is larger, as stated, the increase is solely due to the functional effect of the admixture, and certainly not to the increase in calorific value.

There seems to be a general consensus that the coming fuel for the motor car will be a blend with an alcoholic base. Straight alcohol, which, owing to the unlimited quantities in which it can be produced and the tendency of the price to become lower and lower as the demand for it increases, would be the ideal substitute for gasoline were it not for the fact that for a number

of reasons it is unsuited for use in the bigh speed low compression motor. There is no necessity bere to enumerate these reasons. It is sufficient to say tbat in France and in Germany, wbere the alcobol situation is much further developed than with us, tbe problem of using alcobol in the gasoline motor has reduced itself to the problem of finding a fuel with wbich it can be satisfactorily blended.

Tbe principal shortcomings of alcobol wbich it is sougbt to remedy by blending are its comparatively low calorific value and the tardiness with wbich a mixture of alcohol vapor and air takes fire. A more vigorous ignition and a speedier inflammation are essential if the basic principle of automobile practice of seeking power in the direction of a high revolution per minute rate is to be conserved. The heavy, slow-running motor with a high compression and a large cylinder volume is tbe only alternative, and while possibly admissible for certain forms of commercial vehicle, it is otherwise too heavy and too bulky.

Seeking a Substance to Mix with Alcohol.

While it may be said tbat the admixture of any volatile bydrocarbon of tbe olefiand or aramatic series with alcohol distinctly improves its quality as a fuel, the ingredient which bas found most favor up to the present is benzol. Under tbe name of Motorine, over 2,000,000 gallons of a mixture consisting of equal parts of benzol and alcobol have been used to date by the Paris motor 'buses. It is, however, important to point out that the motors of these vehicles are specially designed to burn this blend, and their satisfactory operation cannot be taken as a proof that an alcobol-benzol mixture is a true gasoline substitute in tbe ordinary motor. As Dr. Ferhmann, the expert of the German government, puts it, "It has been proposed to mix alcohol with other fuels of high calorific value, as, for instance, benzol or ergin, and thus to increase its heating value and above all its inflammability. Witb slow motors good results have been obtained in this manner, but with high speed motors new difficulties arose as a result of the impossibility of completely burning these mixtures, so that there was a great deposit of soot in consequence of the admixture." Alcohol benzol blends bave tbe further disadvantages that the cleanly character of the natural alcohol is entirely lost, and that the exhaust from their combustion is the reverse of odorless. Also from an economic point of view, the sources from which benzol can be procured are not sufficiently extensive or elastic to allow of production on a scale which would be called for to meet a demand for alcohol-benzol mixtures.

In the address by Dr. Warschauer, from which quotation has already been made, the conclusion is arrived at that the best admixture to make alcohol more inflammable is acetylene. He says: "Probably tbe only admixture which is free from these disadvantages is gaseous acetylene. The admixture of alcohol with acetylene has been proposed by several others besides Dr. Roth. Thus, the Americans, White and Barker, bring a spray of diluted alcohol in contact with calcium carbide, thus forming an explosive vapor known as alkoethene. This fuel is therefore a mixture of alcohol vapor, air and acetylene gas. This process, which, besides in America, caused considerable discussion in France, is, however, probably not very practical, for the reason that the acetylene is generated from the carbide directly on the vehicle. Aside from the great weight from carrying along the carbide, this process involves the further objection that the acetylene is generated irregularly, especially on account of the vibration on the road." As one of the inventors responsible for this process, it will not perhaps be considered out of place for the writer to takc the opportunity here of making a brief rejoinder to Dr. Warschauer's objections.

It may be mentioned that in dealing witb the various ingredients which may be added to alcohol, Dr. Warschauer classes acetylene with picric acid, and in the opinion of the writer this association is a very happy one, inasmuch as it touches the real root of the usefulness of acetylene as a corrective for alcohol. Acetylene is not only a fuel in the accepted sense of the term. It is also an explosive. It follows that what we have called the functional action is in the case of its admixture very marked. The trouble with alcobol is its all-around slowness. In a fast-running motor it continues to burn during the entire expansion stroke, and some of it leaves the motor without being burned at all. Now, when a mixture of air, alcobol vapor, and a sufficient proportion of acetylene, wbich need not be considerable, is compressed and a spark passed, the instantaneous rise of pressure in the vicinity of the spark plug compresses the adjacent layers of gas beyond the ignition pressure of the acetylene molecules and spontaneous ignition results. Tbere is thus passed throughout the mixture an energetic explosion wave wbich travels from the spark outwards, the acetylene being progressively detonated owing to its unstable character, the alcobol in wbich it is suspended being ignited at the same time. Under such circumstances the progress of the flame cap is not by direct inflammation from molecule to molecule of the mixture, but by the adiabatic compression of successive zones of the mixture to the preignition point. Now, even on the supposition, which is of course purely imaginary, that tbe acetylene bas no fuel value, its constituent atoms remaining unburned after the liberation of its endothermic energy, the benefit to the combustion of the alcohol would still remain, for the two desiderata of a vigorous ignition and a speedy inflammation would still be realized. If it be further borne in mind that the efficiency with which a fuel can be burned in a given motor is, to take Dugald Clerk's figure, cut in two if it is burned throughout tbe stroke instead of at the beginning of the stroke, it will readily be seen that the gain due to the presence of acetylene in an alcobol-air mixture is largely independent of quantitative consideration. The answer, therefore, to tbe first objection of Dr. Warschauer is that since it is the functional action of the acetylene which is of most consequence, no very great quantity of it is required to accelerate the alcohol sufficiently, and that consequently the weigbt of carbide whicb must be carried along to generate the necessary acetylene is by no means the heavy burden which he supposes, being on the most generous estimate well under 20 per cent. of the weight of tbe alcohol in the fuel tank.

As to the second criticism, it sbould be mentioned that in making alkoethene, the air in the charge is preheated by the exhaust before passing througb tbe carbureter and the carbide chamber. The surfaces of the carbide are therefore always dry and tbe net effect of the shaking is to preserve a clean carbide surface. There results not a variable but a uniform generation of acetylene. If there were no agitation and consequently no accumulation of ash preventing the access of the vaporized dilute alcohol to the carbide with which it reacts, then an unequal flow of gas could reasonably be expected. The practice in acetylene generators of the type where the water is dropped on the carbide, of mechanically shaking the grate on which the carbide rests, may also be mentioned.

Acetylene Appears to Fill All Conditions.

Putting aside now all matters of controversional detail, it is difficult to see how the claim of acetylene as the natural corrective of the faults of alcohol can be put aside. Acetylene has the same percentage composition as benzol, and, like that compound, exerts a reducing action on any acetic acid which may be formed by the combustion of the alcohol. It has the advantage over benzol that it is cleanly; that it can be completely burned in the motor, and that it produces an odorless exhaust.

Lastly, as a commercial proposition, acetylene means carbide, and since limestone and coke, the raw materials from which carbide is manufactured, can be procured in unlimited quantities, the tendency with acetylene, as with alcohol, will be to become cheaper and cheaper as the demand for it increases. Of no other ingredient with which it has been proposed to mix alcohol can the same be said. Even if their tcchnical merits were greater, they would prove but a stopgap, and by their use the problem of finding a gasoline substitute would not be solved but merely shelved for a while. That this problem is a pressing one may be surmised from the fact that there is a standing offer by the French government of $10,000 to the discoverer of a suitable and satisfactory fuel for use in the existing motor.

LETTERS INTERESTING AND INSTRUCTIVE

HOW, WHEN AND WHY TO USE KEROSENE.

Editor THE AUTOMOBILE:

[1,559.]—Will you kindly oblige a subscriber by answering through your columns the following queries:

1. What is the consensus of opinion regarding the practice of periodically treating the cylindere with kerosene? When I first bought a car I was told to cleanee the cylinders with kerosene once a week. Now I hear it aeserted that this does more harm than good. What is one to believe?

2. If kerosene is to be used, how much and how often? Also what is the best method of procedure?

3. Will this treatment avoid the necessity of taking the cylinders down for scraping, provided of course gasoline and lubricating oil have not been used in excess?

4. How often is it well to have the engine taken down? Can the cylinders be properly scraped while in place?

5. How long does lubricating oil retain ite lubricating properties? In other worde, how often ehould the crankcase be drained?

6. "Hold-ups" by highwaymen seem to be increasing at a disagreeable rate. Doee the ordinance, in New York City, for example, against carrying concealed weapons forbid the carrying of firearms in one's automobile? A. G. D.

New York City.

1. We have never heard any objections to this practice and do not see any cause for them except laziness.

2. Many foreign chauffeurs use it after each day's run, pouring a couple of spoonfuls into each compression cock and letting it stand over night. In the morning drain off the dirty oil from the crank case and put in a fresh supply. Most owners find this too troublesome, however, and do so only once a week, or after every five hundred miles. The manufacturer of your car can give you the best advice on this subject.

3. "Provided gasoline and lubricating oil have not been used in excess," it should rarely if ever he necessary to scrape the cylinders. Otherwise, the kerosene treatment will have a very good effect.

4. Have it taken down whenever necessary; this depends on the care it has been given, as above. Whether the cylinders can be scraped while in place or not depends on the design of the motor.

5. This, too, depends on the motor. The crankcase should he drained whenever the kerosene treatment is used, and oftener, if necessary. The manufacturer can advise you best.

6. The law only applies to weapons "concealed," whether in an automohile or not; there can he no objection to carrying them openly. It would not be illegal, for example, to carry your revolver in a holster attached to the seat or the steering column.

AN OLD FRIEND IN A NEW GUISE.

Editor THE AUTOMOBILE:

[1,560.]—I have worked out a method of using up old casings which has been of considerable value to me and, I believe, would be to others. It ie to remove the clincher bead and then put the casing on another as a tread, riveting through both about every six inches on each side. I use ordinary copper rivets about 1-2 inch, with heads shaped as follows: make a mold of a piece of round iron, with the end rounded and a hole drilled for the etem of the rivet, and then putting the rivets in the mold hammer down the heads over the rounded end so as to make them slightly cup-shaped. In this shape they will not injure the tube and are not so likely to pull through. A set of old tires fixed thie way lasted me all last Winter, and a number of my friends use the same method. One might think that a casing would not go over another of the same eize, but with a little care it is easily done.

Chinook, Montana. C. F. H.

We recently printed a letter from a correspondent who had a method similar to this, hut instead of riveting merely punched holes in the old tread and laced it on with a strip of rawhide. Your method is much more workmanlike, of course, hut it is a question whether the old casings are worth so much extra trouble.

CARBONIZING AND EXCESSIVE CONSUMPTION.

Editor THE AUTOMOBILE:

[1,561.]—Will you kindly let me know in the next issue what is the cause of carbon? Have been troubled a great deal in my 1908 car. I use the best oil and do not believe there is anything wrong with the carbureter. I notice in thie particular car the people are all having a great deal of trouble, and I cannot see any cause for it outside of carbureter and oil. Would like to know if there ie any possible way of changing consumption of gasoline by changing the carbureter in any way, such as raising the float, or lowering it, or changing size of hole in jet. I am only getting six miles on a gallon and you can realize this makes expensive running. W. W.

Brooklyn, N. Y.

Carbon deposits in the cylinders are usually caused by an excess of lubricating oil, but may also come from an over-rich mixture. The best way to find out which is responsible is to examine the exhaust gases. Thick bluish-gray smoke indicates too much oil; thin black smoke, together with a very strong smell of gasoline, means that the mixture is too rich. In either case the remedy is obvious. Provision is always made for changing the consumption of gasoline. You had better not tamper with the jet, but the level of gasoline can be easily lowered by adjusting the float. On the car you mention there is also an adjustable shutter over the main air inlet; enlarging the air opening might have the desired effect. The gasoline consumption at present is certainly too large.

TROUBLES AFTER LENGTHENING WHEELBASE.

Editor THE AUTOMOBILE:

[1,562.]—Will you kindly give me your opinion on thie question in "Letters Interesting and Inetructive?" Does lengthening the wheelbase of a small runabout, by placing the rear axle about a foot further back, take off any power in the engine? Or should the loss of power be looked for in the engine? In this particular case my car, a single-cylinder Cadillac, which was a good hill-climber before the change, eeems to have hardly any power at all on a very slight grade, although it rune fine on the level. G. J.

San Francisco, Cal.

There is no reason why lengthening the wheelhase, in itself, should decrease the power in any way. The trouble is that work of this kind usually introduces complications not at first apparent. Placing the rear axle further hack makes the chain run at a considerably different angle, and this, with the added inclination when the car is on a hill, may cause it to drag on one of the axle tie-holts or a cross member of the frame. Any unusual noise would prohably be an indication of this. Again, the hrake connections may have been made to interfere somewhere in the lengthening process, causing the brakes to drag. Finally, remember that you have added at least a hundred pounds to the weight of the car, and on the hills that you are accustomed to climb this may he just the difference between high gear and low.

PROJECT FOR A TABLE OF EFFICIENCIES.

Editor THE AUTOMOBILE:

[1,563.]—As a prospective purchaser of an automobile, without more than the average knowledge posseesed by the public in general upon the subject, and believing that there is a "best" among all products, would it be poesible and agreeable for you to give the public and me through your paper a record of all gasoline makes, based upon the performance of each in competition, where regular stock cars were used. Taking every event in which each make has competed, where there were as many as, say, four cars in the event (except gymkhana contests). For hill-climbing contests figure the best time in any class as par, and the lowest as zero, and the same in races.

Reliability, economy, etc., conteste are usually figured so many pointe off from 1000. For example: "The X car" of all styles and sizes during the year September 1, 1907, to September 1, 1908, had ten cars in competition in this country, and its average for the

ten conteste was 999 pointe out of a poseible 1000. Aleo could not a table be computed on the eame baeie for five years? Price, eize and etyle are not difficult to determine, being largely a matter of individual taete and ability, but reliability, efficiency and durability seem to be the thinge impoesible to get at. M. C. CUMMINGS.

Chicago, Ill.

Such a table would be valuable indeed were it possible to make one, but consideration will show you several difficulties. In all contests the success of a car depends largely on the driver; a second-rate machine driven by an expert can often defeat a really good car with inefficient handling. There are entirely too many disturbing elements for such a table ever to be practicable. To help you out of your difficulty we can only repeat that we believe there are several hundred cars on the market which, with reasonable care, will give perfect satisfaction. If you buy a standard and well-known car from a reputable dealer you cannot go far wrong.

INFORMATION ON SEVERAL SUBJECTS.

Editor THE AUTOMOBILE:

[1,564.]—Please answer these questione through your paper:

1. What le the difference between a live type and a floating type rear axle?

2. Would it be possible, on a belt-driven motorcycle, to loosen the belt and let the motor run independent of the rear wheel?

3. Would you think a V-shaped belt, such ae used on eome of the motorcycles, would be serviceable in mountain dietricts?

4. Could you please give me the addrese of the companiee that publieh the "Motorcycle" in Chicago and "Pacific Motoring" in Loe Angeles? A SUBSCRIBER.

Newman, Cal.

1. The former includes the latter. A live axle is any axle containing parts which turn the wheels, in addition to carrying the weight of the vehicle; as distinguished from a dead axle, which only carries weight. A floating axle is a particular type of a live axle, in which the shaft which turns the wheels is independent of the axle proper, and can be removed without affecting the axle's weight-carrying capacity.

2. It would be possible to do so, by means of an idler pulley, for example, but there would be no particular advantage in such a construction for ordinary use.

3. There is no reason to the contrary, provided the belt and pulleys are of suitable proportions.

4. Motorcycle Publishing Company, 299 Broadway, New York; Pacific Motoring, 1012 South Main street, Los Angeles, Cal.

MORE ABOUT THAT 40 PER CENT. DIFFERENCE.

Editor THE AUTOMOBILE:

[1,565.]—Really you must be joking. But you have made the statement with such earneetness that I will reply. One-ninth of anything is 11 1-9 per cent. of it. One-sixteenth of the same thing is 6 1-4 per cent. of it. Subtract one of these from the other and the difference is slightly under 5 per cent. Can I say any more? Forty per cent. is a lot of difference. No, I neither smoke nor drink. An ice cream will do.

As for the public opinion, I muet stick to my statement that it provee nothing until it has been educated and agitated up to the highest point. I assume that my lawyer, my doctor, my grocer, and my tailor are epecialiets and know their business. When I wish to buy their speciality I aim to take their advice and get the benefit of their experience. If they are wise surely they will do likewise when they come to me for my epecialty.

There could be no progress if there were no leadere. Somebody muet be ahead of the masses. And since there are always leaders, the up-to-date man will keep pretty well up to them. You are not publishing a carriage journal, although carriagee are twenty times ae numerous as autoe. You devote epace to the navigation of the air although public opinion has been almost overwhelmingly against it. And if public opinion le right, I would like to know why it is that motors weighing ten to twenty pounde per horeepower are ueed on autoe in two, four and six-cylinder forms when there are five-cylinder ones to be had which weigh but three pounds to the horeepower. What ban le there on three and five-cylinder forme which the even number escapes?

And why doee the public flop eo often? Right, like truth, le immortal. If the rear-entrance tonneau met the needs of the public, as public approval indicated, why did it die out so suddenly? Simply becauee eomebody learned that eide entrances were better. And eo it goes. Public opinion is simply massed imitation. Jonee wante an auto, knowe nothing about them, so buye what he eees Smith using. Beet and only thing to do—since he will not stop to think about the subject and consider whst he wante to use it for and what it ought to be to meet his needs. And particularly since he will not take the advice of experts. But he does even worse. He eees that Smith's rig is big, so he asks for a bigger one. And many Joneeee make that eenseless thing wbich we call public opinion. The only consolation is thet Jones learne after he has owned a few autoe. CHAS. E. DURYEA.

Reading, Pa.

You have side-stepped the question entirely. The difference between one-ninth of 100 per cent. and one-sixteenth of 100 per cent. is five, or, to be exact, 4.86 per cent., as you say. But the original question was the "percentage" difference between one-ninth and one-sixteenth—something quite different.

In the last part of your letter it looks as if you were arguing against yourself. Motors weighing 10 pounds to the horsepower are used because the three-pound ones are impractical for automobile use. There is no ban on three and five-cylinder forms except their own inherent difficulties. And the public certainly showed its good sense when it adopted the side-entrance tonneau; it "flopped" only because the rear entrance had never met its requirements, and it immediately took up the first thing that did. We think the ice-creams are on you.

MORE ABOUT PERCENTAGE OF DIFFERENCE.

Editor THE AUTOMOBILE:

[1,566.]—In your lseue of September 17 I noticed Mr. Duryea's diecuseion with you ae to the difference between one-ninth and one-sixteenth. If I understand the question correctly tbe difference is only a fraction under 5 per cent. the way I figure it. I aeked another party what he figured the difference to be, and his reeult tallied with mine, although we ueed different methods. Of course figures talk, and if your figuree can talk louder tben mine. I'll take water. CINCINNATI.

Cincinnati, O.

We have answered Mr. Duryea's second letter elsewhere in this issue. You have made the same mistake of confusing the difference between two per cent.'s and the percentage difference. If you want the figures, $0.111 - 0.0625 = 0.0486$; $0.0486 \div 0.111 = 0.437$, or 43.7 per cent. You assume that by one-ninth and one-eleventh is meant one-ninth and one-eleventh of one hundred per cent., for which there is no justification whatever. The one-ninth must itself be taken as equal to one hundred per cent. This is straight arithmetic.

PROPORTIONS OF A GRINDING COMPOUND.

Editor THE AUTOMOBILE:

[1,567.]—I would be pleased to know the exact proportions to make a good valve-grinding compound. I have tried emery, but find it is apt to cut the valve. My idea is to make it up with grease eo that it will stay suspended and be ready at all times. If you could help me in this matter I will certainly appreciate it.

Syracuse, N. Y. A READER.

There are a number of ready-mixed grinding compounds on the market which give good results. If you desire to mix it yourself, the best thing to add to the emery is ordinary cylinder oil, enough to form a paste convenient to work with. The emery you have been using is probably too coarse; try a finer grade.

ARE CHAUFFEURS A DRUG ON THE MARKET?

Editor THE AUTOMOBILE:

[1,568.]—Are chauffeurs a drug on the market in New York? The Motor League of Toronto claims that it has hundreds of applicatione for jobs ae chauffeurs in that city, but no positions open. I am a carpenter by trade and get good wagee in the Summer, but am idle all Winter. I am thinking of going to New York this Fall when the works begin to be tied up to see if I could get in s first-class repair shop and learn how to handle and repair machines. Do you think this would be feasible? I have taken down en Olds 1903 runabout eeveral timee and have handled it on the road, but have no experience with other makes. PERCY N. ROWE.

Prescott, Ont.

The best answer to your question appears to be the old

saying: "There is plenty of room at the top." Chauffeurs of the engine-racing, clutch-banging, gear-smashing type are only too plentiful here, and no more are desired; but we do not think that a really good man would be long without a job. Your experience with the Olds should have taught you the principles of automobile construction, and with this you ought to be able to get a position in a repair shop. We believe that there is a better opening for the average man in the repair shop, however, than as a chauffeur.

FOR THE ATTENTION OF TAXICAB MAKERS.

Editor THE AUTOMOBILE:

[1,569.]—Will you kindly give me through your "Letters Interesting and Instructive" the following:

What are the taxicab rates for fares, etc., in New York, Philadelphia, Boston?

What is the cheapeet taxicab that can be bought and at what price; aleo what would you call the average price for American-made cabs.

Lebanon, Pa. CLARENCE S. WEIMER.

The taxicab rates in New York City are 50 cents for the first mile and 40 cents for each additional mile. For all waits the charge is 10 cents for each six minutes. We cannot give you the rates for other cities, but think that you will find the New York rates about the average. For trips outside of the city there is an additional fare, but this is dependent on the road conditions as well as the distance.

As regards the price of taxicabs, your letter will probably attract the attention of the manufacturers, who will answer this better than we could.

THE SIX-CYLINDER VERSUS FOUR AGAIN.

Editor THE AUTOMOBILE:

[1,570.]—I am undecided in my purchase of an automobile for 1909 between a six-cylinder and a four-cylinder car. Will you kindly tell me in your "Letters" the advantages or disadvantagee a six-cylinder car has over a four?

Corning, N. Y. C. W. M.

You will find material for several large volumes on this subject in the issues of this magazine during the past year, where the question has been threshed out by supporters of both types. To tell the truth, however, we believe that if you buy a car of reputable make you will never have cause to worry about the number of its cylinders.

CONCERNING THE USE OF DECARBONIZER.

Editor THE AUTOMOBILE:

[1,571.]—If my experience with the solution lately put on the market for ridding cylinders of a gas engine of carbon will assiet any of your readere, shall gladly give same. When put on the market last Spring, I secured a half-gallon and from ite continuous use, even during the hot montha, am convinced it ie a most ueeful adjunct to the proper running of an automobile. The directions given with the article call only for use as a cleanser at times, but it has been ueed right along in the cylinder oils in my car, and after any long trip would give the engine an extra cleaning with it, so that my car has not had the least engine trouble as regards over-heating, missing, eooted plugs, etc., since using the decarbonizing solution.

This method was followed: When firet applied one to two ounces were injected into each cylinder after heating up the engine and removing the spark pluge; then the plugs were put back and the engine etarted, letting it run, eay ten minutea or more, until the heavy black smoke iseuing from the exhauet would leesen up, ehowing that the solution had been used up. Then would remove the plugs again and put in each cylinder one-half gun or so of kerosene, attach plugs again, start the engine, and run as before until all the dirt and carbon were entirely blown out.

I then etopped the engine, opened the pet cocks attached to pipes, one under each cylinder, driven into the engine case, therby draining the caee of few quarte of black, sandy-like, sooty oil, which one readily could see would do no engine any special good. When all of it was removed, then I put back the normal amount neceesary for my case, two to three quarts, with eix drams, or three-quarters of an ounce of the decarbonizer eolution mixed thoroughly into a gallon of the oil. Through the oiler (tank) to the different parts of the engine fed by thie oiler, goee the eame mixture of oil and decarbonizer—3-4 ounce to the gallon—so that the engine is constantly using the decarbonizer, and the pluge from this car wnen removed are as white and clean as porcelain can be made.

I first made comparative teets from 10 ounce to the gallon down to 1-2 ounce to the gallon, and found at 3-4 ounce to the gallon the solution which kept my pluge clean. When 10 ounce to the gallon solution was used, engine heated greatly; cut thie to 5 ounce, still it heated, but not so much—plugs still white, but leae heat; then cut it to 2 1-2 ounce to the gallon, still plugs white, but lees heat; then 1 ounce to the gallon, plugs still juet as white, but no extra heating noticed at all, even on hot days; then thought I would do better by cutting to 1-2 ounce to the gallon, when I noticed plugs, when removed, were eilghtly brownish, so tried 3-4 ounce to the gallon solution, which I found the solution necessary for my particular engine. I might add that each time I changed these eolutione, the oil case was emptied with the oil gun and case filled with the mixture to he tried next; aiso the engine case drained and same strength mixture of oil and decarbonizer put back as wae being ueed in the oil case. While wasting some oil from the engine case, the experiments have well repaid me, ae I have the first trouble to occur yet from a choking engine.

In mixing the decarbonizer with the oil, better take a gallon at a time to shake it thoroughly and more easily. I have never used it in the gasoline, as I have heard reports of this manner of ueing, but should think it more economically used in the oil; aleo get to the place quickest where it is needed—in the combustion chamber. If there would he no splashing in the cylinders from the caee, then plain oil would be necessary only in the case.

To satisfy myself that the cylinders were in no way being affected, I had them off two months after ite use, and the walle of the cylindere, pietons, piston rings, etc., were juet as clean as if scraped and polished; the only place where there was carbon was on each baffle plate between base of cylinder and engine case, and thie was held there, as it could not properly get out to be blown through. The exhaust valvee had very little carbon attached, and the engine power is to-day juet as good aa after thorough overhauling.

Allentown, Pa. PALMER J. KRESS, M.D.

THE LOZIER'S MISHAP IN THE LONG ISLAND RUN.

[1,572.]—In your iseue of September 24, deecribing the incidents of the Long Ieland Mechanical Efficiency run, the etatement was made that H. M. Cashrunt'e Lozier motor broke ite differential and etripped its geare when attempting to get out of the deep sand between Amaganaett and Montauk Point. We know that thie was the common report, and you were, therefore, in a measure juetified in accepting the report ae true, but ae thie car did not break its differential and did not etrip ite geare, we believe that you will promptly make thie correction and give publicity to the following fact:

Mr. Caebrunt was an amateur driver and owner of his car, entering on his own initiative. On the first day's run, after luncheon he left the control without the authority of the committee and raced to Amagansett at a epeed of 50 to 55 milee per hour, in violation of the epeed lawe and the rules of the run. Unfamiliar with the road, he continued through the eand strip toward Montauk at racing epeed, with wheels at times up to the hubs in sand. In the eevere etrain of these conditione, the epider holding the differential geare was broken—an accident, by the way, which has never occurred before. Not a differential gear or a gear of any kind was damaged, stripped, or hroken, and when the spider was replaced, Mr. Casbrunt returned under his own power.

We have stated upon honor publicly, and repeat the statement, that there has never been a case of a broken or replaced differential or transmission gear or a broken or worn gear tooth, or one showing eufficient wear to require replacing, and we repeat this statement, and aiso the statement which we have publicly made that we do not believe that there will ever be a case of a broken gear or gear tooth in a Lozier shaft-drive car.

In view of the above facts, you can understand our wish to have thie erroneous statement corrected.

LOZIER MOTOR COMPANY,
C. A. EMISE.

MORE ABOUT MINIMUM SPEED ON HIGH GEAR.

Editor THE AUTOMOBILE:

[1,573.]—Concerning the controverey in your columne over the minimum speed of a car on high gear, probably the average driver finds that a great deal depends on the condition of the road eurface. On a perfectly smooth and level pavement I find it difficult to keep my speed down as low ae 8 or 10 miles an hour on high gear, hut where the surface is very lumpy, for example, on a bad cobble pavement, I experience no trouble in running at 3 miles an hour as shown by the speedometer. A maker's statement as to "4 to 40 miles on the high," or words to that effect, is therefore generally true enough if you put a grain of ealt in the right place.

New York City. R. M. PIERSON.

ANOTHER EXPONENT OF THE TWO-CYCLE MOTOR

ANOTHER addition to the growing ranks of the two-cycle exponents is the Bailey, manufactured by the Bailey Automobile Company, of Springfield, Mass. It is only after five years' experience with two-cycle engines that the Bailey Company has finally placed a car upon the market. It claims to have made radical improvements on all other two-cycle engines in use in automobiles, and also to have the most powerful two-cycle, four-cylinder car in the field. The Bailey is built in two models, one a three-seated speedster and the other a touring car; both are listed at $2,500.

Cylinder Casting, Showing Intake Valve.

Simplicity and sturdiness are the features of the power plant. The cylinders are cast separately, each with the upper part of its respective division of the crankcase integral. The lower half of the case forms the support of the whole motor, and has arms extending to the frame. Five long bearings of high-pressure metal carry the crankshaft and retain the pressure in the crankcases. One of the objections urged against the two-cycle engine is that wear on the crankshaft bearings will permit leakage of compression from one crankcase compartment to another, thereby reducing the power of the engine. However, as the present production of the Bailey Company shows no sign of leakage through the bearings after a very hard punishment over 6,000 miles of rough roads, this contention may be questioned. The shaft itself is made of vanadium steel with hardened and ground journals.

After a careful study of the problems involved, the Bailey Company adopted the automatic valve inlet, which is considered both simple and reliable. It admits a fresh charge to the crankcase during the entire aspiration stroke, thus causing no jerky suction on the carbureter as does the three-port system, while it has not the objectionable feature of friction in the crankcase, as in the type with rotating disc valves. The automatic valve may be seen on the base of the cylinder in the illustration; the intake manifold is clamped down over the valve. The cylinders are copper-jacketed, making a uniform jacket which can be replaced in case of accident at a very low cost.

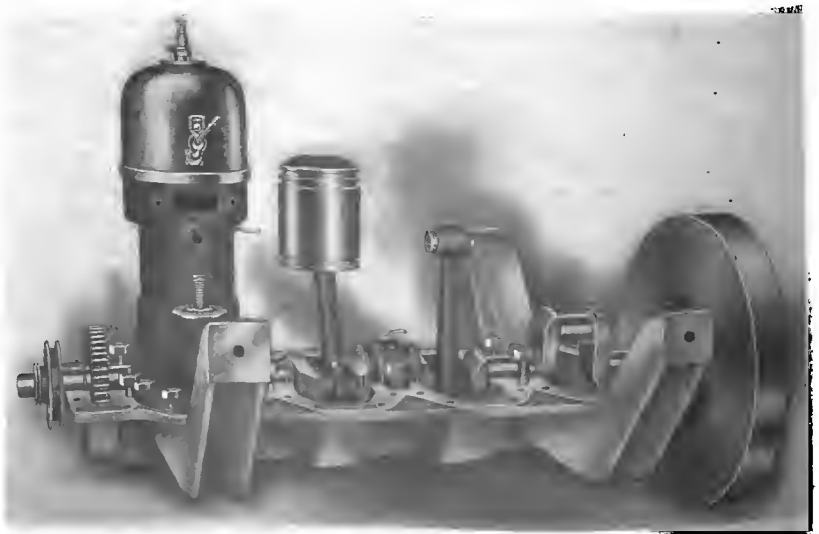
The change-gear used is the three-speed selective sliding gear type with Timken roller bearings, connected to the engine by a multiple disc clutch of the most approved type. Timken roller bearing axles are also used; the front axle is a very strong I-beam, the rear of the floating type, with bevel drive. The springs are long and easy riding. The frame is a four-inch pressed steel channel, hung very low; the wheelbase is 112 inches.

The speedster recently made a trip from New York to Springfield in four and three-quarters hours and returned in five hours, a total of 325 miles. The company is housed in a new reinforced concrete building located on Birnie avenue, and is equipped with modern machinery throughout. With these increased facilities, the output for the coming season will be considerably increased, and the Bailey will be put on the market outside of Springfield.

It is still regarded as a rather venturesome experiment for a new company to undertake to build two-cycle cars, and no doubt with reason. The automobile-buying public has only just begun to learn the advantages of this type. It has its disadvantages as well, of course, and especially for the manufacturer. The designing of a two-cycle motor is a thing not to be undertaken lightly; a few thousandths of an inch change in the placing of a baffle plate, for instance, may make all the difference between success and failure. Then, there are as yet few standards for the beginner to follow; each must depend on his own knowledge and ingenuity, and work out every new problem for himself. Considering these difficulties, it is not to be wondered at that most designers, in spite of its many alluring possibilities, have preferred to give the two-cycle a wide berth. No one can predict the outcome of the struggle between the two types; hut, in any case, the Bailey Company has the credit of being one of the pioneers who obtained for the two-cycle a fair trial.

NEW ELECTRIC WILL BE BUILT AT TOLEDO.

TOLEDO, O., Sept. 28.—The Toledo Electric Vehicle Company, which has recently been organized with $50,000 capital, will manufacture electric runabouts. An old riding academy building on Collingwood avenue has already been leased, and machinery will shortly be installed. The company is an outgrowth of the Allen & Clark Company, which operated several months at 2014 Adams street. This concern being of the nature of an experimental firm, was organized with a limited capitalization, and formed for the purpose of improving an invention of A. F. Clark whereby, it is claimed, he is able to build a battery which will, at low current, carry an electric car further than any other battery known and at a rate of about 30 miles an hour.



Bailey Motor Partly Dismounted, Illustrating Method of Mounting Cylinde

COLUMBIA MODELS ARE AGAIN TO THE FORE

By CHARLES B. HAYWARD

HARTFORD, CONN., Sept. 28.—Activity is obtrusively in evidence at the great plant of the Electric Vehicle Company these days. A day spent at the monster works of this pioneer in the country opens a visitor's eyes to the creditable accomplishments of the hustling administration of H. W. Nuckols, the receiver, and Fred Law, the chief engineer. To see between 500 and 600 men at work is to convince one of the vitality of the famous plant and its progress toward a resumption of its former position in the automobile industry. The number of men employed has reached more than 50 per cent. of normal and is being gradually increased. The decks have been cleared through the working up of the material on hand into finished cars, the last of which were sold early in August.

Lines of Columbia Mark XLVIII 29-Horsepower Car for 1909.

For the coming season, a series of 100 of the new Mark XLVIII-4 30-horsepower gasoline cars is already on its way to the assembling department and deliveries will begin by October 10. At the same time a series of 50 of the Mark LXX electric victorias is also going through. A number of the best agents has been retained, and with Receiver Nuckols acting as sales manager, in addition to his multitude of other duties, there has been no difficulty in disposing of the cars as fast as they can be turned out. A second series of 100 of the gasoline cars will be started about the end of November in order to make a stock available for show selling.

New Models Have Their Distinctive Features.

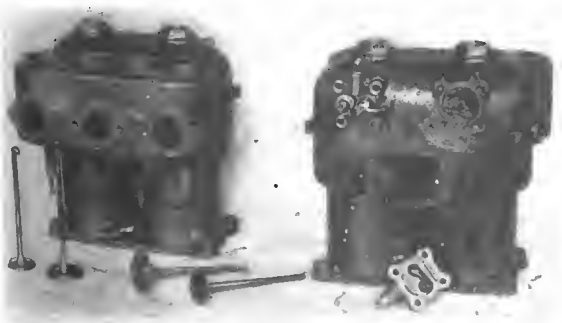
In the case of both the gasoline and the electric car, they are new models in the full sense that the word is currently employed. In other words, they are not merely replicas of the former output of the Electric Vehicle Company, but, building on these as a foundation, they have been refined and improved in not a few particulars. Where the electric car is concerned, there is naturally not a great deal of change to be noted, though both the running of the car and its mileage, as well as its service generally, have been greatly improved by the adoption of the Hess-Bright ball bearings in the running gear. Two cells have been added to the battery, bringing its voltage at the terminal up to 72, and a few other minor changes have been made, though so far as its external appearance goes, the car is the same as the many thousands of others of its kind that the company has turned out in the past, and which are now in use all over the country.

A review of the specifications of the Columbia gasoline car shows that its design has been the subject of a great deal of study on the part of Mr. Law since his return to the factory, two years ago. The price has been cut $250, now being $2,750 instead of $3,000, as formerly, but, gauging it from the standpoint of service and worth, the value of the car has been increased by more than double that amount by the improvements that have been effected concurrently with the cut of the list figures.

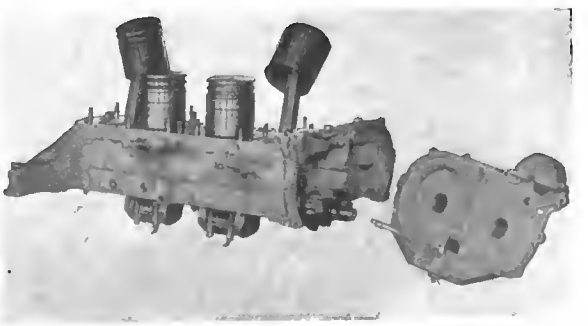
Principal Details of the Power Plant.

The motor is of the four-cylinder vertical type, with the valves on one side, but, contrary to the usual practice, the valves themselves differ in size. The inlet measures 2 1-4 inches, giving an opening 2 inches in the clear, while the exhaust is 1 13-16 inches in diameter, giving a 1 5-8-inch opening, the lift being 3-8 inch. The cylinder dimensions are 4 1-4-inch bore by 4-inch stroke, the output being 28.9 horsepower, according to the A. L. A. M. formula. The car will nominally be known as 29-horsepower, which rating is developed at a moderate normal speed, though even at the latter it shows a great deal higher figure on the brake, and, owing to its excellent valve and port design, it is capable of being speeded up to a very high r. p. m. rate at full load. One of the most noticeable features of the motor design is the H-B annular bearings on the timing shafts, so that the gears are practically supported between bearings. Bronze and nickel steel pinions are used and are protected by an oil-tight aluminum housing. Ball bearings are also employed on the forward ends of both the pump and magneto shafts.

The Electric Vehicle Company was one of the first concerns in the industry to put in a complete drop forging plant, and can probably boast as extensive a collection of dies, designed especially for automobile work, as is to be found anywhere in the



Twin Cylinders from Valve and Ignition Side.



Crankcase with Crankshaft and Piston Assembly.

Columbia Rear Axle Driving Unit Complete.

country. Drop-forgings are accordingly utilized to a liberal extent, a special grade of nickel steel being used and every part being subjected to heat treatment. Such parts as the one-piece camshaft, connecting rods, differential housing cover, and radius rod frame attachment—the last two calling for particularly intricate dies—the one-piece I-beam front axle, besides a large number of smaller parts, are all made by drop-forging. As a matter of fact, the plant is so completely equipped that everything but the wheels, tires, radiators, and side-frame members is turned out.

The chrome nickel steel crankshaft is another drop-forging of E. V. make which receives particular care. It is of the three-bearing type with an unusually liberal factor of safety in its bearing dimensions, the flywheel end bearing measuring 4-7-8 inches, while the center and front are 3 1-2 inches, the journal being 1 1-2 inches in diameter, which, together with the special grade of babbit employed, doubtless accounts for the manner in which this very essential part of the Columbia has alays stood up. The flywheel fastening is unique in design; it consists of the usual flange, but the latter carries two dowels and six studs. All are of chrome nickel steel, and the studs are provided with thimble ends which are screwed into the flange and riveted into countersunk recesses, then being finished flush. They correspond with holes in the flywheel casting which is held snug against the flange by six castellated nuts. The one-piece camshaft operates the valves by the direct thrust method, while the timing gears are of the spiral type with a 1-inch face cut at a 10 degree angle.

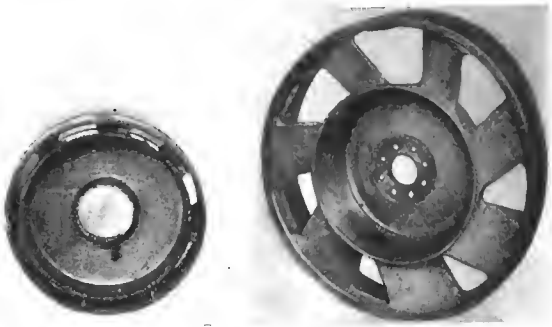
About the Motor's Accessories.

Painstaking care has been devoted to the design of the motor's accessories, the handling of the fuel and oil not alone being made as simple and efficient as possible, but likewise economical. The carbureter, which is one of Mr. Law's special designs, has a double jet, the smaller opening of which is controlled by the governor and affords speeds up to 25 miles an hour with excellent fuel efficiency. This spray jet is also controlled by the hand throttle, and is suitable for all ordinary running, giving 15 to 16 miles to the gallon of fuel. The large jet is entirely independent, and is controlled by an accelerator pedal; it is intended only for speeding. A constant circulating type of lubrication is provided, a gallon or more of oil being carried in a small cylindrical tank hung from the frame. From this it is pumped through a stand-pipe, the height of the motor, from which it is discharged to all the bearings and is then returned to the tank. A bleeder consisting of a 2-inch glass cup is located on the dash and connects with a short shunt tapped into the stand-pipe two or three inches from its return bend, so that the presence of oil in the glass is a certain indication of its circulation. The connecting rod big ends are provided with adjustable scoops to facilitate the splash, the crankcase being cast to form baffle plates to prevent excess oil finding its way into the cylinders. Ignition is by low-tension Bosch magneto, the design of the lens-bar having been considerably improved over previous models.

Some of the Drop-forgings Made in the Home Plant.

The Transmission and Running Gear.

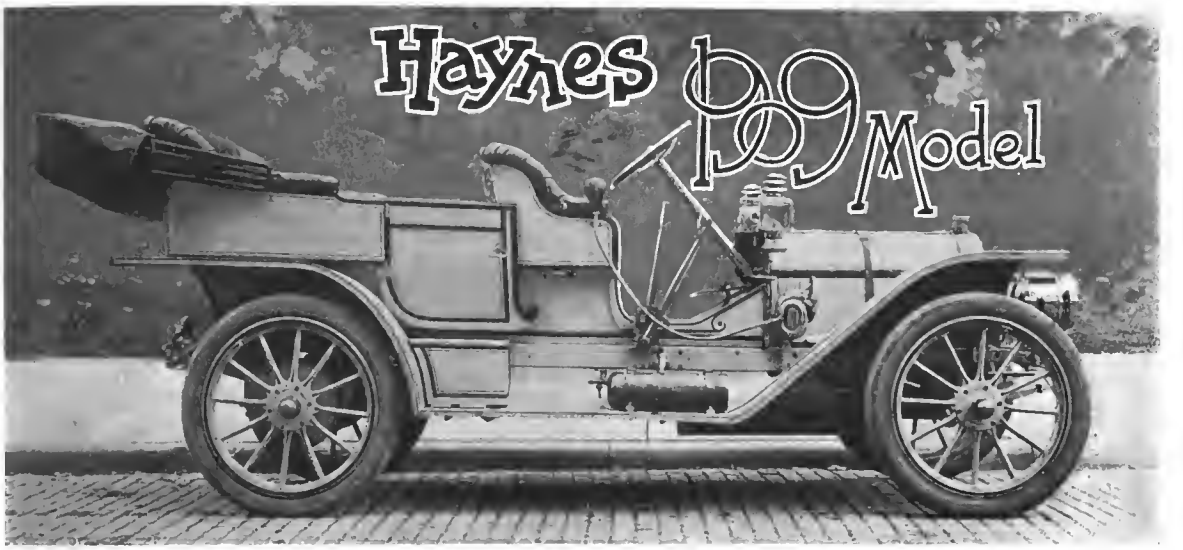
The clutch is of the plain conical leather-faced type, while between it and the propeller shaft is a three-speed selectively operated gear-set running on Hess-Bright bearings. In its control this gear-set is unique in that the hand lever, instead of picking up supplementary levers in the housing, engages with small rocking levers placed in the sector itself. Shifting laterally engages these by means of a square jaw formed on their upper ends, when the different speeds may be obtained by moving backward or forward an arrangement that works very easily and is proof against sticking. The universals used between the clutch and gear box and on the propeller shaft are of the yoke type and are turned out in the home factory, as are also both the steering gear and the entire rear axle driving unit, with the exception of its Timken bearings, which are also used in the wheels.



Fan Spoke Cooling as Applied to Flywheel and Brake Drum.

In order to make an absolutely rigid member of the rear axle, the tubes are brazed into the housing in the rough. The axle is then placed in a hydraulic press and the center pressed downward slightly. This lack of alignment is then corrected by the press rod, the turn buckles of which are permanently pinned in place, once the axle is straightened. By this means opposing stresses are set up which tend to keep the axle rigid. The entire axle is then placed in a lathe and the wheel ends turned, following which it is clamped in a jig and bored both ways, thus insuring absolute accuracy of alignment. In the case of the motor, this is accomplished by clamping the support in a jig and running long reamers through the openings for the bearings, while similar accuracy of alignment of the motor and gear-set supports on the frame is obtained by placing the latter complete in a jig with the brackets and cross braces assembled in the rough. The supports are then milled to a level face.

Another excellent feature is the assembly of the brake drums and rear wheels before boring. They are thus turned directly on the cups for the Timken bearings, which makes for absolutely true running. These drums are not only of unusually liberal dimensions, but also have an air space between the internal and external bands, with fan-shaped spokes or braces, similar to a flywheel. The front axle is a one-piece die-forging of nickel steel, specially heat-treated; suspension is by means of semi-elliptics front and rear, the dimensions not having been altered since last year, although the wheelbase has been increased to 115 inches and 34-inch wheels adopted. The Hartford rim and Hartford tires are fitted, 3 1-2-inch front and 4-inch rear, though the make is optional. A five-passenger touring body or a limousine fits this chassis interchangeably. The company is also building a car with a 5 1-2-inch "square" motor with an A. L. A. M. rating of 48-horsepower and four-speed selective gear with shaft drive, but will only turn them out as ordered.



THE Haynes Automobile Company, of Kokomo, Ind., will build only one model for 1909—a four-cylinder 40-horsepower car to be known as Model X. This is the successor of the 1908 Model W. The Haynes Company found that this model, medium in both power, size and price, appealed to by far the greatest number of purchasers, and decided that better results could be obtained by concentrating the entire factory organization on this one type. Models S and U were therefore discontinued. It has now been found possible to make many improvements on the original design without raising the price from the 1908 figure, $3,000.

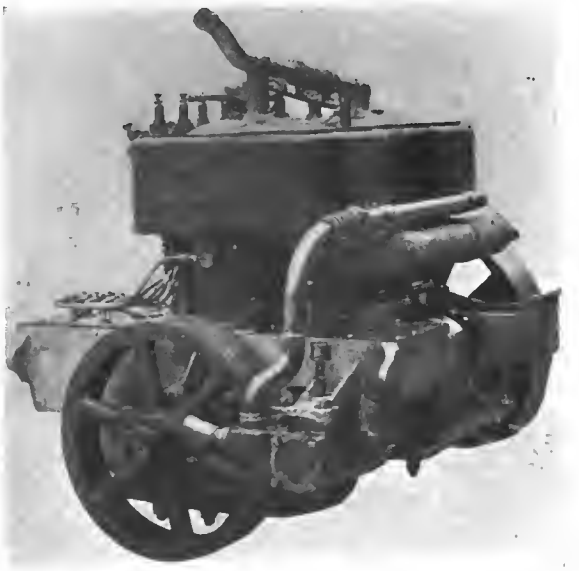
The Motor of Familiar Design.

No one in the least acquainted with former Haynes models will fail to recognize the motor. The cylinders are 4 3-4 by 5 inches bore and stroke, and are cast in pairs, with valve pockets on opposite sides. The valves are of unusual size, 2 5-8 inches in diameter; the heads are nickel steel electrically welded to the stems. Each piston has three composite rings; these consist of a heavy, plain ring, on the outside of which are two thin rings, broken at opposite sides and pinned quartering the break in the inner ring. The latter provides the expansive force, while the thin outer rings conform perfectly to the shape of the cylinder. The combination is unsurpassed for the holding of compression, and yet is very free in action. The crankshaft is turned from a heavy bar of vanadium steel, which has previously been roughly forged to shape. It runs on double sets of conical roller bearings at each end and a center bearing of Parson's white bronze.

The right-hand forward arm of the crankcase is cast in box shape, and in it is embodied the McCord oiler, gear-driven from the inlet camshaft. The corresponding arm on the opposite side is used as an oil reservoir, and is connected with the gang of pumps by a small passage in the forward part of the case. This allows an ample supply of oil to be carried for long tours. The lower section of the crankcase is divided into four separate pits for the cranks, so that the oil cannot all run to one end when on a grade. The two-to-one gear, as well as those driving the oiler on one side and the magneto and water pump on the other, are carried in a separate compartment and packed in heavy oil, thus reducing their noise to a minimum.

Two systems of ignition are provided, each entirely separate and distinct from the other. A dry-cell battery gives current for one, and a single coil with high-tension distributor completes the outfit. The other is a high-tension magneto, located on the left side of the motor. The two sets of plugs are both placed directly over the inlet valves.

The water pump is of the eccentric type, which the Haynes Company has retained after many years of experience. There are comparatively few moving parts, and their movement is very slight; it has the additional advantage of giving a positive circulation.

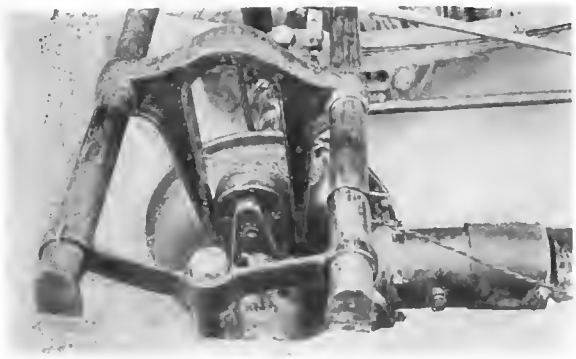


Front Quartering View of Haynes Motor with Double Flywheel.

Clutch and Master Gear.

The clutch is of the contracting band type, and is similar in action to the ordinary brake. It works on a bronze drum, which is supported in the flywheel by four arms forked at their outer ends. These forks straddle corresponding lugs on the inner side of the flywheel rim. Between each lug and the ends of the fork on either side coil springs are interposed, thus forming a shock absorber between the motor and the change-gears to eliminate strains attendant upon the sudden engagement of the clutch.

The change-gear gives three speeds forward and one reverse, controlled selectively. The master gear on the countershaft drives through a ratchet; in shifting from a higher



Haynes Improved Roller Torsion Lever.

to a lower gear, this allows the car to run ahead of the motor until it slows down to a speed corresponding to that of the latter. It is thus impossible for the momentum of the car to be exerted through the gears, and in consequence gear-stripping has been practically eliminated. The bearings of both main and countershafts are specially designed rollers, and they are carefully fitted with stuffing boxes to prevent leakage of oil.

The universal joints of the drive shaft consist of three parts—two heavy steel yokes and a square steel block. The yokes have large flat inner surfaces which bear on opposite sides of the block. Cross pins hold the block in place, but the driving strain all comes on the broad surfaces. The joints are both covered with heavy leather boots to protect them from dust and mud.

The Roller Pinion and Sprocket Drive.

The method of power transmission at the rear axle is peculiar to the Haynes, and is fully covered by patents. Instead of the usual bevel gear and pinion, a device is used which is known as a roller pinion and sprocket. The driving member consists of a shaft with two integral flanges, between which, at proper intervals, pass large steel pins. The pins in turn carry rollers, which engage the large, coarse teeth of the sprocket ring on the differential. It is, in fact, a bevel gear with roller-bearing teeth. Practically the only parts which ever show any wear are the pins and rollers, and these can be easily and cheaply replaced.

Instead of the usual torsion rod the Haynes employs a torsion roller. It is carried on a heavy arm projecting upwards from the differential easing and works in a slotted guide supported by the main frame, deep enough to allow it to move up and down with the action of the springs.

The two separate sets of brakes are both contracting and are located side by side on the rear hubs. The drums are 14 inches in diameter; the bands of the foot brakes are 1 1-4 inches wide, and those of the emergency 1 1-2 inches. The drums are hollow and may be filled with water if desired; thus they will never overheat, no matter how strenuous the service.

Choice of Body Equipment.

The touring body which is regularly provided seats five persons, but there is sufficient room in the tonneau for side seats accommodating two other passengers. The front seat is divided. All bodies are made of wood, carefully selected and seasoned. In the upholstery, nothing but the finest of hand-buffed leather and gray curled hair is used, together with the most up-to-date springs. On the runabout the seats are placed about six inches further back and are quite low; the dash is hooded. This type can be equipped with either one small rumble seat on the rear box, two small seats, or two full-sized seats.

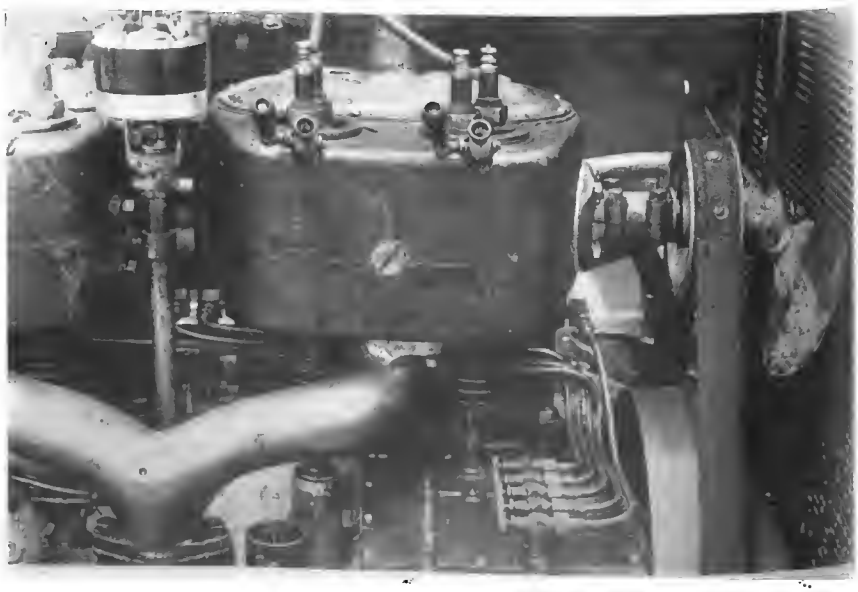
Still another type is euphoniously named the "Hiker"; it is much the same as the runabout, except that it accommodates two passengers only. The seats are set very low and tilted up about an inch and a half higher in front than in back. Behind the seats is a large cylindrical gasoline tank. Last of the line is the toy tonneau; this is simply a four-passenger touring car. The front seats are placed in the same relative position as on the runabout, thus shortening the tonneau space. The rear seat is narrowed to a width suitable for two passengers. This style of body is made to meet the demand for a light, comfortable, four-passenger body to be fitted to a regular chassis.

COOK JOINS FEDERAL RUBBER COMPANY.

CUDAHY, WIS., Sept. 28.—Otis R. Cook, who for twelve years occupied the position of general representative for the B. F. Goodrich Company in its tire department, and for the past two years held the same position with the Firestone Tire and Rubber Company, left the latter company October 1 to accept the position of general manager of the Federal Rubber Company's tire department, of this city. Mr. Cook states that this is a new departure for the Federal Rubber Company, which is a large manufacturer of mechanical and molded rubber goods, and will add to its line pneumatic automobile tires, solid motor and truck tires, solid rubber carriage tires, also a full line of bicycle tires and accessories.

Mr. Cook has associated with him Osborne S. Tweedy, who will occupy the position of sales manager, and who will look after all matters pertaining to the sales at the factory. Mr. Tweedy needs no introduction to the trade, having been connected with the Diamond Rubber Company for fifteen years as manager of that company's Chicago branch.

The Federal Rubber Company announces that it will put on the market the highest class of automobile and motor truck tire that is possible to produce and that its pneumatic auto tire will be sold to manufacturers and jobbers under special trade marks.

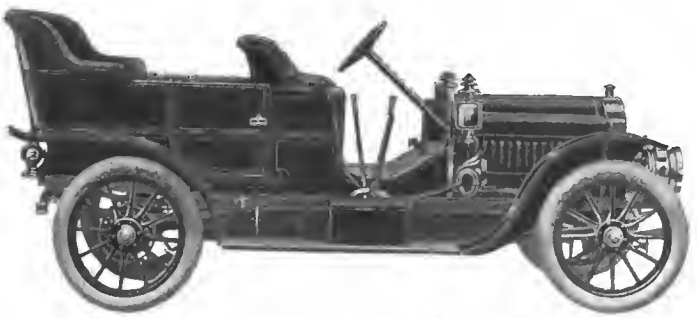


Inlet Side of Haynes Motor, Showing Oiler; Oil Tank on Opposite Side.

THE 1909 MODELS OF THE TWO-CYCLE ELMORE

ALTHOUGH numerous changes have been made both in design and mechanism, the 1909 Elmore two-cycle models will be practically a continuation of the 1908 models 30 and 40. The appearance of the cars has been considerably improved by lengthening the tonneau and raising the radiator and hood to bring them into proper proportion, and there are a number of refinements in detail.

The motor remains the same Elmore valveless two-cycle which has had such marked success in the past, with three cylinders on the 30-horsepower model and four on the 40-horsepower. The cylinders of both are 4 1-2 inches bore and 4 inches stroke. Perhaps the most radical change is the offsetting of the cylinders on the crankshaft to give a more direct downward thrust on the power stroke. The performance of the new motor shows a decided improvement over former models, both in power and steadiness. The carbureter is the regular Elmore float-feed automatic type. The lubricating system of the last two years is retained; the oil is fed into the inlet pipe, thus insuring its equal distribution in each cylinder. The side countershaft of the motor has been dispensed with, and the Atwater-Kent spark generator, which the Elmore company says has far exceeded all claims or expectations, is now driven directly.



Model 44 Four-cylinder Two-cycle Elmore for 1909.

The clutch mechanism has been considerably improved and simplified by placing the actuating spring directly behind the cone. The Brown-Lipe selective change-gear, with annular ball bearings, three speeds forward and reverse, is retained, but the support is now by integral arms, instead of from crossbars. The drive is through shaft and Spicer universal joints, which have given perfect satisfaction in the past. The front axle, of the drop forged I-beam pattern, has been modified to allow the lowering of the frame about two inches. Exhaustive tests have resulted in the retention of the rear platform springs, though a new form has been adopted that gives much softer action, regardless of the load in the car. The new springs are very finely graduated, with an increased number of leaves thinner in proportion.

The general lines of the Elmore body remain unchanged. The popular straight back, with rounded corners, is retained in the three-cylinder model. The tonneaus of both models have been lengthened, and special attention has been given to the upholstering. Mahogany dash and trim are used on the three-cylinder and Circassian walnut on the four. The height of the radiator has been increased 1 1-2 inches, not to afford larger cooling surface, but to bring the hood into better proportion with the rest of the car. Model 44, which is shown in the illustration, has a wheelbase of 112 inches, and 34-inch wheels shod with 4-inch tires. Model 33, the three-cylinder, resembles it in outline, and has a 104-inch wheelbase and 32x3 1-2 tires. An addition to the Elmore line is a landaulet mounted on the three-cylinder chassis. The roadster has been changed considerably in general style, and is furnished with two sets of rear seats, one single and one double. Thus the roadster may be called three cars in one; it may be used with flat deck, with single or with double seat.

DETROIT MAKERS ENJOY UNUSUAL PROSPERITY

DETROIT, Sept. 28.—Prosperity is being spelled in large letters these days by Detroit automobile manufacturers and makers of parts and accessories. On every hand unwonted activity prevails. Plants are running close to their capacity, and orders for next season's cars are coming in before the present year's output has all been produced in a most gratifying manner.

Within another week the working force at the Cadillac Motor Car Company's plant will be doubled, furnishing employment to 1,600 more men, and permitting the concern to work steadily day and night in order to meet the demand for its new models.

At the plant of the Ford Motor Company everything is humming, and district managers in session here a few days since gave assurance of an increase of 100 per cent in the volume of business for next season. Every energy is being directed toward completing the new factory for the Ford, at Highland Park, just north of the city, and which will, it is claimed, be the largest automobile plant in America. It is expected to be ready for occupancy by the first of the year.

The Everett-Metzger-Flanders Company, while just getting fairly started in the old plant of the Wayne, has already disposed of 6,000 cars, half of next season's anticipated output, through the Studebaker Company, and orders are coming in rapidly from other sources. Work will shortly be commenced on an immense addition to the present plant.

Of course, the Packard Motor Car Company is doing all the business it can care for the immense plant with its 3,500 employees being in full operation.

The Detroit-Chalmers is another concern enjoying its full share of the present prosperity, while the smaller concerns all report favorably on the outlook.

Parts makers are jubilant over the prospects, and the present year promises to be a successful one all the way around.

BALTIMORE TO HAVE AUTO AMBULANCES.

BALTIMORE, Sept. 28.—Motor-driven ambulances will be used by the local fire department service hereafter to convey injured firemen to hospitals, and for disabled horses of the department. On recommendation of Chief Horton, the fire commissioners have ordered two of these ambulances—one for men, one for the veterinary department.

AUTOS IN TOLEDO'S CIVIC PARADE.

TOLEDO, O., Sept. 28.—The automobilists of this city will participate largely in the civic parade to be held here the present week in connection with the annual fall festival. It is intended to make the auto division a leading feature of the procession to typify the advance of locomotion methods. The local club will add its influence, and a representative turn-out is expected.

BOOKS FOR AUTOMOBILISTS.

"The Amateur Motorist."—Max Pemberton is so well known as a writer of fiction that most readers would be apt to set his latest publication down at first glance as another addition to the long list of automobile novels of the "best sellers" class. Perhaps some will regret that it is not; for if we must have automobile novels, far better have them written by a master of the subject than by one of the type whose heroes "grasped the speed lever and the huge machine bounded forward" for twenty chapters. However, Mr. Pemberton's book is, as the name implies, simply a plain and sensible guide for the prospective automobilist.

The usual chapters are devoted to the exposition of the principles of the motor, carbureter, ignition, gears, etc., and these are written in a simple and non-technical style. Their only drawback is the constant use of English terms apt to be confusing to the average American. We are used to "tyres" and "petrol," but that "star-wheel" means a bevel gear is hardly so apparent. Following this comes some very good advice to the beginner as to the size and type of car to buy, whether or not to employ a chauffeur and, if so, how to keep tab on that gentleman, how much he should expect his car to cost for upkeep and much other useful information. Finally Mr. Pemberton catalogs all the best known English and Continental makes, giving the different models and sizes and the advantages claimed for each. Unfortunately this part, which was evidently very carefully done, will not be of much assistance to the American automobilist, as only a few of the cars described are known in this country and only one of them is of American manufacture. Chapters on motorboating and motorcycling are also included.

The volume is bound in plain and workmanlike style, as befits a text-book, and is illustrated with many full-page photographs of men and cars, as well a sdrawings explaining the text. The publishers in this country are A. C. McClurg and Company, of Chicago, and the price $2.75.

"Road Preservation and Dust Prevention," by William Pierson Judson, C. E., provides a much-needed source of information on a subject which is being brought more and more to the attention of the public. The book should be studied by the road officials of every State and city in the country. It aims to furnish the information clearly and concisely, and is easy reading for anyone interested in the question. Much needless expense can be incurred and much damage done by attempts to use oils and other road binders without sufficient knowledge of the suitability of the material for meeting local conditions. Mr. Judson is a recognized authority on the subject, and has given details of many personal experiences. The book is published by The Engineering News, 220 Broadway New York City.

A "WORLD'S TOUR" OVER JERSEY HILLS.

MADISON, N. J., Sept. 28.—There is to be another automobile "tour of the world" among the hills of Morris county, N. J., this autumn, along the lines of the motor car trips for charitable objects promoted in the past by the fashionable folk of the Oranges and Montclair. The tour is to be the joint promotion of the Y. M. C. A. branches at Morristown and Madison and the Boys' Brigade and Girls' Club of Chatham, under the corporate title of the "International Touring Company," whose president is James H. McGraw, and the general manager is Herbert Strong.

The date set is Saturday, October 18. The route laid out covers some 15 miles. The cities to be visited are: "Madrid," J. H. McGraw, Madison; "Yokohama," C. M. Decker, Madison; "Berlin," F. C. Blanchard, Morristown; "Constantinople," L. B. Tompkins; "Damascus," Homer Davenport, Morris Plains; "Pekin," J. M. Gifford, Chatham, and "Washington," C. F. Wheeler. The national capital, which will be the starting point of the tour, will show the White House, a G. A. R. post, and a booth of Puritan maidens.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows and Meetings.

Dec. 31-Jan. 7..—New York City, Grand Central Palace, Ninth Annual Automobile Show, conducted by the American Motor Car Manufacturers' Association, with Exhibits by the Importers' Automobile Salon, Inc., Alfred Reeves, General Manager, 29 West 42d St.

Jan. 16-23.....—New York City, Madison Square Garden, Ninth Annual National Show of the Association of Licensed Automobile Manufacturers. M. L. Downs, Secretary, 7 West 42d St., New York City.

Feb. 6-13.....—Chicago Coliseum and First Regiment Armory, Eighth Annual National Exhibition, National Association of Automobile Manufacturers. S. A. Miles, Manager, 7 East 42d St., New York.

Mar. 7-13.....—Buffalo, Second Annual Power Boat and Sportsman's Show, Convention Hall, Dal H. Lewis, manager, 760 Main Street, Buffalo, N. Y.

Races, Hill-Climbs, Etc.

Oct. 1-2.....—Indianapolis Two-day Reliability Run to French Lick Springs and Return, Indianapolis Automobile Trade Association.

Oct. 2-3.....—New York City, Brighton Beach Track, 24-Hour Race, Motor Racing Association.

Oct. 6-9.....—Chicago, 1,000-Mile Reliability Run, Chicago Motor Club.

Oct. 7-9.....—Cleveland, O., Three-day Reliability Run of the Cleveland Automobile Club.

Oct. 10.....—Providence, R. I., Narragansett Park, Race Meet, Rhode Island Automobile Club.

Oct. 10.....—Philadelphia, Founders' Week Stock Chassis Race, 195 Miles, Quaker City Motor Club.

Oct. 10.....—Long Island Motor Parkway Sweepstakes, Conducted by Vanderbilt Cup Commission.

Oct. 10.....—Providence, Narraganeett Park, Race Meet, Rhode Island Automobile Club.

Oct. 10.....—Morristown, Madison, Chatham, N. J., Automobile Carnival and "Tour Around the World," under Y. M. C. A. auspices.

Oct. 17.....—Hartford, Conn., Hill Climb, Automobile Club of Hartford. (Probable Course, Avon Mountain.)

Oct. 24.....—Vanderbilt Cup Race, Long Island Course, auspices of Vanderbilt Cup Commission.

Nov. 26.....—Savannah, Ga., Grand Prize Race, Savannah Automobile Club.

FOREIGN.

Shows.

Sept. 24-Oct. 4..—Bourges, France, International Exhibition for Agricultural Motors.

Oct. 11-18.....—Paris, International Congress and Public Exhibition on Roads and Road Making for Modern Locomotion, French Ministry of Public Works.

Nov. 28-Dec. 13.—Paris, Eleventh Annual Salon de l'Automobile, Grand Palais, Automobile Club of France (Pleasure Vehicles, etc.)

Dec. 20-28.....—London, Stanley Show, Agricultural Hall.

Dec. 22-29.....—Paris, Eleventh Annual Salon de l'Automobile. (Commercial Vehicles, etc.)

Jan. 16-25.....—Brussels, Show Organized by Belgian Chamber Syndicate, Palais du Cinquantenaire.

Races, Hill-Climbs, Etc.

Oct. 2.....—France, Gallion Hill Climb.

Oct. 11.....—Berlin, Germany, Gordon Bennett Balloon Race, Aeronautical Club of Berlin.

UNJUST VERDICT AGAINST AUTOIST REVERSED

HARTFORD, CONN., Sept. 28.—Judge John Coats of the Court of Common Pleas is surely not a motorphobe or anything of like nature, for he has just set aside a verdict rendered the owner of a horse outfit which got in the way of a slow-moving automobile some time ago. The verdict was in favor of the horse owner, and was for $150. Commenting on the above-mentioned verdict, Judge Coats says: "Upon a careful examination of the evidence, I cannot escape the conclusion that manifest injustice would be done to the defendant if the verdict in the case should be allowed to stand. In my opinion, the verdict is so manifestly contrary to the evidence that I cannot escape the conclusion that the jury disregarded the instruction of the court respecting the law in the case, or mistook the evidence, or were influenced by prejudice or partiality in reaching their verdict."

DETROIT ADOPTS THE PACKARD FIRE WAGON

DETROIT, Sept. 28.—The Detroit fire department has inaugurated an automobile system which is not only a departure from ordinary fire department practice, but which promises such increased efficiency that the fire chiefs of all the large cities in the country are closely watching it. The new vehicle is a Packard "Thirty" touring car chassis converted into a fire wagon with a special body and equipment, making it suitable for carrying a squad of firemen about town with the speed of the fastest touring car. The truck is now located at one of the stations, but will eventually have a separate house built for it. It has its own organization of fifteen picked men, including captain and lieutenant, forming what is locally called the flying squadron, the purpose of which is to reinforce any regular company in the city in time of need.

Packard "Thirty" Fire Wagon, Placed in Service by Detroit Fire Department.

The fire fighting forces of Detroit have been in need of enlargement for some time. Last winter the legislature passed an act authorizing an increased annual expense of about $190,000. After considerable study of the proposition, the fire commissioners decided to use automobiles and a small number of men, instead of a large number employed in the usual way. They therefore asked several automobile companies to bid on the manufacture of a special wagon which would have all of the speed and general efficiency of a high class touring car and at the same time be able to carry a normal load of twelve men. The contract was given to the Packard Motor Car Company, and last week the wagon made its début as a fire-fighting machine.

The chassis is practically standard with the exception that it has heavier springs than the touring car, in order to take care of the additional load. The twelve men are carried, two on the front seat, six on the lengthwise seats of the tonneau, two on the rear running board and one on each side running board. Special handles are provided for the men on the running boards. Provision is also made for carrying three hand fire extinguishers, two on each side and one in rear.

AN AUTO ENGINE AND HOSE WAGON COMBINED

INDIANAPOLIS, IND., Sept. 28.—The Independent Hose Company, of Frederick, Md., has recently installed a piece of apparatus manufactured in this city which differs considerably from other adaptations of the automobile for fire-fighting service. It consists of a hose wagon and fire-engine combined, and with its driver takes the place of an ordinary hose wagon, a steam fire engine, four horses, two drivers and an engineer. As a hose wagon it will carry 1200 feet of hose at a speed of from four to thirty-five miles an hour, and as a water-throwing engine it has the capacity of a third-class steamer. The chassis carries a six-cylinder automobile motor of 60-75-horsepower, connected with a six-cylinder eccentric-operated pump in such a way that the change from road-wheel drive to pump drive can be made by the movement of a lever.

At a recent test at Frederick, Md., before some of the leading mechanics and automobile experts of the State, it threw a 1 1-8 inch stream over a church steeple 150 feet high, and threw two 7-8 inch streams 180 feet and three 3-4 inch streams 160 feet. Needless to say, that fire was settled in record time.

The manufacturer, the Howe Engine Company, of Indianapolis, is now building another machine of the same type which will carry two 35-gallon engines besides regular equipment.

Howe Auto Engine and Hose Wagon, Recently Installed at Frederick, Md.

THE KIND OF EFFORT THAT COUNTS.

Such gatherings as that of the Associated Automobile Clubs of New Jersey held last week at Atlantic City, count more for the general good of automobiling than a score of high speed racers, and in this direction and similar channels the real work of the various State bodies of the American Automobile Association should be kept centered. Best of all, in the success of the good roads convention at the New Jersey seashore resort, the dominating feature was the hearty manner in which the State Grangers, freeholders, and county engineers entered into the proceedings; in fact, if anything, it was more their affair than that of the autoists, who filled the part of hosts and listeners, and obtained much instruction thereby. It was to be expected that the trade would do its share towards making the event possible, for one of the unusual things was the transporting in autos of the delegates from all parts of the State, and 'tis safe to say that not a few of the Grangers had their first autoing experiences and secured impressions not unfavorable to motor-driven travel.

First came the 1907 convention of the Automobile Club of Springfield, Mass., with its excellent motto of "Good Roads and the Sane Use of Them"; next followed, in July last, the national assemblage at Buffalo, under A. A. A. auspices, and New Jersey has kept up the right kind of work with a few improvements that deserve special notice. There was no legislative talk at Atlantic City relating to the automobile itself; but the conventioners expressed themselves as being in favor of a law that would permit the visiting of the autoists of adjoining States, as long as they had gone through the registration necessity at home. That a decidedly more harmonious feeling exists, is a fact that admitted of no doubt at Atlantic City, and the understanding reached is an indication of joint results in the future. Supporting a common cause—the building and mantenance of up-to-date roads—the farmers and the autoists can bring about a system of highways which will put into the background those famous old Roman roads, and also the roads for which Napoleon gained so much credit. And the day is near at hand when the farmer will travel over those roads in an automobile, while "Old Dobbin" eats contentedly in the back lot, unannoyed by any regrets of the days which are gone.

* * *

WHY EVERY MAN SHOULD DRIVE HIS OWN CAR.

In Turkey and in Japan, we believe, no well-conducted gentleman would permit himself to be seen waltzing about a ballroom floor. Instead, when the mood comes upon him, he sends out round the corner and hires a troupe of dancers to disport themselves on his parlor floor. He leans back among the cushions and looks on. We copy the East in many ways; among other things, some of us hire chauffeurs to drive our automobiles.

This custom may arise either from laziness or from ignorance. It is possible that if the Turkish gentleman ever experienced the delights of gliding over a polished floor to the strains of the "Merry Widow," he would renounce for all time the traditions of his country and devote his fortune to the endowment of dancing academies. Likewise, if some of those automobile owners who now are content to loll in the tonneau, once took the wheel in their own hands for a fifty-mile spin on good macadam, the chauffeur would get his week's notice before the last dust cloud had settled.

Many persons, when it is suggested that they learn to drive their own cars, allege that they have no "mechanical bent." That excuse might have passed five years ago, but not to-day. Thousands of men draw both profit and enjoyment from their machines in chauffeurless bliss, who yet have only the vaguest of ideas as to what it is that purrs so gently under hood and footboards. Not that this state of mind is to be encouraged; but it does not often last. Many and many a time has the man who deplored his lack of mechanical inclination become a crank of the deepest dye, and even those who retain their mental perspective easily pick up the knowledge necessary to drive and care for the car. Really, there are few things simpler than the driving of an automobile. In a surprisingly short time it becomes as automatic as walking, and in no way detracts from the pleasures of the ride. This does not include learning to nurse the motor up each hill on high gear, or to drive sixty miles an hour on country roads, or to do acrobatic stunts in city traffic. But somehow, when an owner, ignorant of these accomplishments, has managed the car for a few months, the repair bills show a truly remarkable shrinkage.

JERSEY GRANGERS AND AUTOISTS TALK GOOD ROADS

ATLANTIC CITY, N. J., Sept. 26.—If the other State associations of the American Automobile Association will follow the plan of the Associated Automobile Clubs of New Jersey, they will quickly discover that the differences supposed to exist between the farmers and the automobilists are easily adjusted, for the needs of the two are certainly harmonious when it comes to the subject of good roads. And when farmer and autoist discuss the problems of highway construction and maintenance, they must inevitably touch upon the use of the roads, which means that both quickly recognize the rights of the other upon the aforesaid roads.

For two days members of the New Jersey State Grange, freeholders, and county engineers, and automobilists absorbed good roads from all points of view, the final summing up being of decided benefit and a generally better understanding all around. From various parts of the State the grangers, freeholders, and engineers were brought to Atlantic City in automobiles, thanks to the co-operation of the New Jersey Automobile Trade Association, with J. H. Wood as the chairman of transportation.

President W. C. Crosby, of the Associated Automobile Clubs, who presided during the greater part of the session, fell into the clutches of a speed trap while conveying three freeholders to the city by the sea. It might be mentioned that these three freeholders agreed thoroughly with the driver of the car that the speed limit was not being fractured to any alarming extent, and, incidentally, they obtained ideas on "trapping."

President Walter E. Edge and the other members of the Atlantic City Automobile Club did much to entertain the visitors, including "A Night in the Kitchen" at the Royal Palace Hotel, which entertainment Friday night was novel and very satisfactory up to a late hour.

Owing to illness, Governor Fort was unable to attend, and, therefore, his address did not follow the remarks of welcome, supplied by Mayor Stoy. But there were speakers in plenty, including some impromptu contributors, for there were general discussions after the fixed papers had been given.

Those Who Talked the Most.

The list of speakers included G. W. F. Gaunt, master of the New Jersey State Grange; J. M. Beldon, Essex County Road Drivers' Association; Frank Bergen, Elizabeth, N. J.; J. B. R. Smith, New Jersey Commissioner of Motor Vehicles; Deputy Road Commissioner R. D. Beeman, of Pennsylvania; James E. Owen, Newark, N. J.; George C. Diehl, Erie County Engineer, Buffalo, N. Y.; Deputy State Engineer Gettman, of New York State; Calvin Tompkins, New York City, and Allerton S. Cushman, acting director Bureau Public Roads, Department of Agriculture, Washington, D. C.

The more than 200 delegates applauded loudly when Granger Gaunt, before introducing the resolutions summing up the convention, said:

"We farmers are not opposed to the motor car; we realize that it is here to stay, and welcome both the automobile and its driver. We fully realize that it will revolutionize road transportation, and that it will be an important feature in making farm life more attractive. When the motor car becomes cheaper in price through more general use, the farmer will be the first to adopt it for business and pleasure. I stand ready to promise the automobilists that the grangers of this State will co-operate with them in bettering not only the condition of the roads but the lot of motorists, who, it appears, have been legislated against too severely."

Motor Vehicle Commissioner Smith in the course of his remarks said:

"Present road regulations have been rendered entirely inadequate by the great strides in development and improvement of vehicles. But if we expend out energy in antagonism, it is a waste of time. Our duty lies not in attempting to oppose the opposition, but rather in showing them that our stand is correct and converting their opposition into support. In connection with this, it is well to remember that the power and usefulness of the great motor vehicles when used properly are only equaled by its destructiveness and uselessness when used improperly."

Mayor Linkroum, of Hackensack, was one of the supplementary speakers, and his remarks found much favor. Said he:

Farmers Will Soon Have Autos.

"The farmer of the future will have a motor vehicle to convey his product to market. When he gets this—and I don't believe it will be a question of more than five years—he can just as well live 75 miles from New York as two. Such an improvement will, therefore, enhance the value of farm lands and our farms will be worth at least $200 an acre. Every dollar that the State of New Jersey expends for roads to-day will be gotten back in increased realty values. Within ten years I believe motor vehicles will be so reduced in price that the farmer can buy one to carry several tons for $1,500. Just as soon as this is possible, the horse will go. It's a fact that you can buy a fair runabout to-day for $400, and the price is decreasing all the time."

Col. Frederick Gilkyson, New Jersey State Commissioner of Public Roads, was the honorary guest of the convention, and in the absence of Governor Fort he read a paper prepared by the chief executive, who took occasion to refer most favorably to the proposed boulevard from Atlantic Highlands to Cape May.

Dr. Cushman made a stirring address, and in it asserted that the American farmer is paying annual mud taxes of $250,000,000.

Frank Bergen, of Elizabeth, took a fall out of the present system of improving the present crooked roads instead of straightening the highways between important points.

At the concluding session of the convention representatives of various road building and dust prevention concerns were given an opportunity to set forth the merits of that which they speak for. This feature was not entirely unattractive, and might well be incorporated in future gatherings of a like character.

In making a success of the convention none worked harder than Secretary H. A. Bonnell, of the State body, while other prominent autoists on hand were: George A. Post, president of the North Jersey Automobile Club; D. R. Anthony, Automobile Club of Hudson County; Frederick H. Elliott, secretary American Automobile Association; Dr. J. H. English, ex-president New Jersey Automobile and Motor Club; Jacob Mason, of the New Jersey Automobile Trade Association, and other notables.

Resolutions That Were Adopted.

These were the resolutions, passed unaminously, summing up the sentiment of the meaty convention:

WHEREAS, It is the universal opinion, and particularly of this convention, that improved highways are a valuable asset to any State in its development and progress; and

Whereas, such highways are growing more and more to be the channels of communication and intercourse as well as of trade, be it

Resolved, That it is the opinion of this convention that the materials, so abundantly provided by nature along the various highways, be utilized, so far as is practical, in the construction of such highways and the development of such highways system.

Resolved, That this convention and the organizations represented pledge their support, moral and active, in all movements tending towards the improvement of our highways and the development of our system of highways.

All Users of Highways Should Be Courteous.

Resolved, That it is unanimous sentiment of the representatives of the various organizations here present, that not only is it right and proper, but it is also most expedient and of vital importance to the interests represented that all users of the highways, and particularly automobilists, should be extremely careful and always keen and alert to observe strictly all the courtesies and decencies

of highway travel and should make it their constant aim to persuade, or if necessary, to compel those who are inclined to abuse their privileges upon the highways to conform to those rules of fair and reasonable conduct which already govern the vast majority.

Resolved, That the State Highway Department be requested to issue in pamphlet form information as to the proper and most improved method of the care of unimproved highways.

Resolved, That it is the unanimous sentiment that a good roads convention should be held once each year in New Jersey.

Favor National Aid in Roads.

WHEREAS, The farmers of the United States, through their principal organization, the National Grange Patrons of Husbandry, favor the enactment by Congress of legislation providing for Federal appropriations for public highway improvement and maintenance; and

Whereas, the policy of national aid for road improvement is of great importance to all users of our highways and should be established by appropriate legislation at the earliest possible date; therefore be it

Resolved, That this convention endorses the proposition that a portion of the national revenues should be annually appropriated in aid of the construction and maintenance of improved public roads, and urges Congress to enact legislation for this purpose.

In Favor of Reciprocal Registration.

WHEREAS, We are convinced that New Jersey has lost much from motorists of other States, because of our refusal to allow the use of our highways without the securing of a yearly license, has affected many business interests in the State, we believe that a duly restricted reciprocal arrangement with other States would be to the best interests of all; and

Whereas, It is noticeable that considerable neglect is apparent in keeping many of the improved roads of the State in proper order, we respectfully recommend that a pamphlet be prepared by the State authorities on the proper and scientific repair and maintenance of improved roads and be distributed among the county boards of freeholders, supervisors and other interested officials.

Fees and Fines for Road Maintenance.

WHEREAS, The State has received a considerable sum of money from motorists for license fees and fines, which was supposed to revert to the repair of improved roads, but which, for various causes, has not been entirely appropriated; and

Whereas, It is understood that there is some doubt whether by existing laws such income can be so appropriated; be it

Resolved, That it is wisdom of this convention that the issue should be made very clear and that the entire income from this source should be reappropriated to the repair of State highways outside incorporated city limits.

COMMERCIAL VEHICLES IN FRENCH ARMY MANEUVERS

PARIS, Sept. 25.—Two army corps, comprising 100,000 men have been dependent on the automobile for their daily supply of bread during the period of sixteen days that the annual army maneuvers have been in progress. Two much experience has been obtained in army automobile transport service for there to have been any possibility of the troops being delayed for lack of supplies, but there is still much to be learned in the operation of large numbers of motor vehicles in convoys.

With headquarters at Vierzon, in the center of France, the seventy automobiles were divided into convoys each having a load capacity of from 40 to 50 tons of provisions per day. The routine was for all vehicles to load up at night, make a daybreak start in convoys, reach the regimental headquarters 30 to 40 miles away, and there discharge their loads into the horse wagons distributing them to regiments at the fighting line.

Unlike previous years, the officer in charge of each convoy was provided with a fast automobile, enabling him to run up and down the line and assure himself that all the vehicles maintained their distances of 30 yards, and that there were no breakdowns on the road. In previous years the officer in charge has ridden on the leading vehicle, in which position he was able to set the pace, but had no opportunity of verifying the march of the following units.

The great majority of the military wagons were loaned to the authorities by manufacturers for the duration of the maneuvers only, the drivers being mechanics who were undergoing their period of military instruction. Only about twenty vehicles of various types were supplied by the War Department. The total number of commercial vehicles used during the maneuvers was seventy, this not including the fast touring cars employed by staff officers, or the motorcycles for carrying messages.

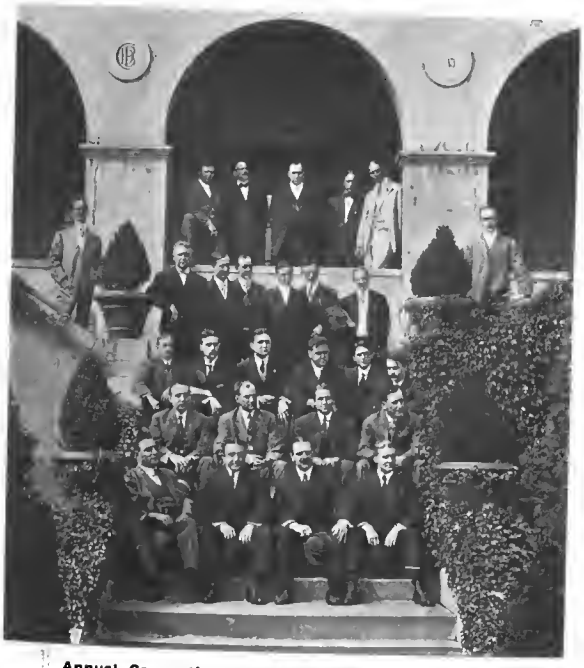
The most important units in the army automobile transport service were three Renard trains, each consisting of a tractor and three six-wheel trailers, two of them being open trucks and one a closed van. The Aries Company supplied the only other vehicles with trailers, the outfits being four-ton wagons trailing a two-wheel vehicle linked up close behind. The Empress Company of Paris put in fewer than ten trucks, varying in load carrying capacity from two to five tons. Berliet supplied five of their standard commercial vehicles, Peugeot and De Dion each had three, one of the latter being specially fitted up for the cycling brigade, and the following firms each supplied one or two vehicles: Cohandet, Latil front-drive, Panhard, Dietrich and Darracq-Serpollet.

During the time that the privately owned vehicles were under military orders they were supplied with fuel and oil, and granted an indemnity of 20 cents per horsepower per day. Each driver was entitled to an indemnity of 20 cents per day.

Commercial Vehicles Leaving Place de la Concorde, Paris, at the Start of the Recent Trials.

ANNUAL MEETING OF FORD MANAGERS.

The Ford Motor Company has made a point of annually assembling all their branch managers at the home office in order that the business of the past year may be discussed and new plans formulated. The convention of 1908 was called for September 15, 16 and 17, at which time the following members of the Ford clan answered to the roll call: H. B. White, Paris; B. M. Thornton, London; R. M. Lockwood, New York City, Foreign Department; F. R. Fox, Toronto; G. M. McGregor Walkerville; C. E. Fay, Boston; Gaston Plantiff, New York City; L. C. Block, Philadelphia; E. R. Stearns, Buffalo; M. D. Coate, Cleveland; H. Cunningham, Detroit; T. Hay, Chicago; W. C. Anderson, St. Louis; Charles Hendy, Denver; C. C. Meade, Kansas City; R. P. Rice, Seattle. The reports from all the agents were encouraging, especially about the prospects for 1909, and all managers pledged themselves to double the sales for the coming year. Besides the business meetings and time spent inspecting the new Ford product, model T touring car, each day found some form of entertainment provided which helped to make this annual gathering of the Ford interests the most successful meeting ever carried out.



Annual Convention of the Ford Branch Managers.

Top row, from left to right—John Dodge, John Anderson, Ed. Dodge, Frank Kulick, D. Gray; second row—L. A. Holmes, James C. Couzens, F. M. McGregor, F. R. Fox, Stanley Roberts, N. A. Hawkins, Henry Ford; third row—R. M. Lockwood, M. D. Coate, H. B. White, W. C. Anderson, Charles Hendy, H. B. Harper; fourth row—R. P. Rice, Thomas J. Hay, Roger Stearns, Harry Cunningham; bottom row—L. C. Block, Gaston Plantiff, C. E. Fay, C. C. Meade.

SALE OF TOLEDO POPE PLANT.

TOLEDO, O., Sept. 28.—Announcement has just been made that a deal has been practically closed whereby D. B. Apperson, Lynchburg, Va., becomes owner of the Toledo plant of Pope Syndicate, known as the Pope Motor Car Company, and, further, that arrangements have been made whereby the factory will be run to full capacity.

Mr. Apperson first tried to acquire the plant several months ago but negotiations fell through, and they have been renewed several times during the interim until now all details have been arranged. Just what settlement will be made with the creditors is unknown as yet. An offer was made of 33 1-3 per cent. some time ago, and only this week an offer was made of twice that amount, the offer coming from some Hartford, Conn., concern.

Iowa Business Men Trying Out 1909 Cadillac "Thirty."

SELLING METHODS BY A WESTERN AGENT.

All sorts of original schemes have been produced by automobile agents to get the prospective purchaser interested in the particular machine they were selling. The latest stunt in this line comes from Cedar Rapids, Ia., where the local agent for the Cadillac, G. H. Henderson, had a number of business men in line for the 1909 model Cadillac "Thirty," but had been unable to get a demonstrating car. These future owners becoming anxious to see the new product, the agent chartered a Pullman sleeper for Detroit and filled it with Cedar Rapids citizens. The next morning, on arrival in Detroit, the party was immediately taken to the Cadillac factory, where enough machines were supplied to hold all, and they were shown the city at the same time the new car was being demonstrated.

FAST TRIP OF THE AMERICAN TRAVELER.

INDIANAPOLIS, IND., Sept. 26.—A 1909 American of the "Traveler" type recently finished a remarkable 2,500-mile trip from Indianapolis to Boston and return. The trip was made under actual touring conditions, the car carrying four passengers, baggage, extra tires and complete road equipment. No attempt was made at long-distance speed records, although the car proved its ability to maintain speed remarkable for a machine weighted down as it was. Stops of a day—frequently two—were made in cities.

The route eastward led through Cincinnati, Pittsburg, Philadelphia and New York, and on the return through Albany, Buffalo and Cleveland. The trip between Johnstown, Pa., and Philadelphia—a stretch of rough mountain roads, crossing the highest ridge of the Alleghanies—was made in eleven and one-half hours, and from New York to Springfield, Mass., the distance was covered in eight hours and fifteen minutes without a stop. V. A. Longaker, president of the American Motor Car Company, and Fred I. Tave, the designer, alternated at the wheel.

Designer Tave (at wheel) and President Longaker (in rear seat) in the 1909 American Traveler.

News In General

E. W. Jordan and Party in Franklin Car on Hunting Trip in Colorado.

A Rocky Mountain Hunting Trip.—Even the humble burro is being replaced by the automobile. When E. W. Jordan, of Palisade, Colo., and a party of friends set out on a hunting trip into the heart of the Rockies they pressed into service a Franklin touring car. The run of forty-eight miles from Palisade to the hunting grounds was made with comparative ease, although over almost impassable roads, up and down steep mountainous grades; the last twelve miles led over a trail where no vehicle had ever before passed. In addition to the party of five, a complete outfit weighing about 500 pounds was taken along. A mountain lion and several wildcats and coyotes were bagged during the hunt.

Renault Trucks in America.—Paul Lacroix, general manager of the Renault Frères branch in New York, announces that the Renault trucks have met with such favor abroad that the company has decided to bring out two distinctly new types for 1909. The larger truck, with a carrying capacity of 3,500 pounds, will have a 14-20-horsepower four-cylinder engine, and the smaller truck a 10-14-horsepower two-cylinder engine of 2,000 pounds. The first American order has been placed with the New York *Herald* for seven of the larger type and one of the smaller, to use in their delivery service around the city.

Useful Advertising Signs.—During the summer a Chicago man while touring through New England lost his way one night near Springfield, Mass., and happening to notice some advertising signs near the road found that they had been put up by the Fisk Rubber Company, at Chicopee Falls, just out of Springfield. The tourist concluded that these signs would lead him into the city, which they did, as they are placed at frequent intervals on the trees and fences. This instance goes to show that such signs are not always as objectionable as some people think.

Studebaker Company Well Equipped.—The Studebaker Company has just completed a successful test with their new auto buggy and feel that with this added to their already large variety of motor vehicles, they are about the largest manufacturers of automobiles in the country. Dr. E. Ford, of the Studebaker Company, does not see how the product for the present can be improved upon, as they are now building everything in the gasoline line from the auto buggy to the finest of limousines; and in the electric field everything from the small runabout to the heaviest trucks. He seems to think that the only way to enlarge will be for the company to go into the airship business and bring out a complete line of dirigible balloons and aeroplanes. "However," says Dr. Ford, "until the demand for airships is more urgent than at the present time, we will probably concentrate on automobiles, but don't for a moment think that should the demand arise we will not be perfectly ready to build as complete a line of airships as we now have in automobiles."

Autos in Waterway Convention.—Ira M. Cobe, president of the Chicago Automobile Club, has sent out a call for 1,000 automobiles to be used on the afternoon of October 9 to show the waterway convention delegates around the city. The club sent out return postal cards to all the members, asking for the loan of their machines, and half the required number have already been promised. During the convention the Chicago Association of Commerce will have as its guests both William H. Taft and William J. Bryan.

Again the Farmer.—Word comes from Manchester, Conn., that a farmer in that vicinity has been showing his neighbors that to farm it in these times one should own an automobile. This individual acquired an old touring car which he was able to fix up in shape to do all that he demanded of it and this year when the potato crop was gathered the other farmers carted them to cellars for storage, while he went them one better and hauled his to Hartford in about the same time they were spending storing theirs away.

New Los Angeles-San Diego Record.—On September 23 L. D. Harvey, of the San Francisco branch of Thomas B. Jeffery & Company, lowered the record for the round trip of 335 miles between Los Angeles and San Diego by one hour and six minutes, making the distance in 11 hours and 22 minutes. Harvey used the same car, a Rambler model 34-A, that he used in his attempted record run between San Francisco and Los Angeles when he was held up for violating the speed laws.

Firestone Company's Clever Plan.—All sorts of methods have been resorted to by the tire manufacturers to produce a tire that would not skid, but it has been left to the Firestone Tire & Rubber Company, of Akron, O., to make use of a very clever scheme which they claim makes the nearest approach to a non-skid tire on the market. This new tire has the name "Firestone Non-skid" placed in raised letters around the body of the casing so that the name itself tends to prevent skidding.

New Continental List.—The Continental Caoutchouc Company has issued a booklet announcing a new schedule of prices, with considerable reductions from the former figures, which went into effect September 21. It also contains instructions for the use of "Ready-Flated" tires and the handling of the removable rims. The Continental motto is still "The greatest amount of mileage at the least tire expense."

Still Another Use for a Car.—With a view to economy of a great deal of time, the head gardener, Charles E. Murray, at Washington University, St. Louis, purchased a Ford roadster to take the place of a horse which he had been using for mowing the lawn. Hitching the mower on behind the machine he now does the work of mowing the 130 acres in a few hours, while the horse took at least two days.

Oakland Joins A. M. C. M. A.—The latest recruit to the membership of the American Motor Car Manufacturers' Association is the Oakland Motor Car Company, of Pontiac, Mich., makers of the Brush runabout. The officers of this company are: President, E. M. Murphy; vice-president, A. P. Brush, and sales manager J. B. Ecclestone, of Buffalo.

Continental Tires in India.—During the past three months a Stella car fitted with Continentals made a 5,000 mile tour in India, Malay Peninsula, China, and Java, over roads that had never been attempted before in an automobile. During the entire trip the tires were not touched once, rather a remarkable experience under any conditions.

Louisville Will Have Taxies.—The success of the taxicab in many of the large cities has led John Roche, W. E. Coldway and L. K. Delph to organize a company which will maintain a service in Louisville. The new firm, the Louisville Taxicab Company, has been incorporated with a capital stock of $5,000.

Auto Service to Briarcliff.—An automobile coach service has been inaugurated between the Manhattan Hotel, New York City, and Briarcliff Lodge, in Westchester County. It is intended that the service will be maintained throughout the Fall, two cars a day being run each way.

IN AND ABOUT THE AGENCIES.

Oldsmobile, Philadelphia.—The Olds Motor Works, heretofore represented by the Motor Shop, 317-319 North Broad street, Philadelphia, has established a branch house, which was put into operation October 1. A portion of the newly built structure at 231-233 North Broad street has been secured, and "Billy" Taylor, former factory representative of the Oldsmobile in the Philadelphia territory, has been appointed manager. This territory will include, besides Eastern Pennsylvania, all of Delaware, Maryland, Virginia, the District of Columbia, and the southern half of New Jersey. Manager Taylor has announced that it is the policy of his company to open sub-branches and agencies in all the principal cities of this territory, and that within a short time a regular factory branch will be established in Pittsburgh.

Pope-Hartford, New York.—The sale of Pope-Hartfords in New York City is now in new hands. The Pope Manufacturing Company has given the metropolitan agency for its product to the Pope-Hartford Auto Company. The new agency has leased and is now in possession of the former quarters of the Wayne, at 1853 Broadway, near Sixty-first street. At the head of the concern is B. E. Holt, a gentleman of wide commercial experience, though not, however, previously associated with the automobile business. His associates, B. E. Fincke and C. A. Dickson, respectively treasurer and secretary, are well known to the industry through prominent connection with the local trade at Newark, N. J.

G. & J.—The newly organized Berrodin Rubber Company has purchased the Philadelphia Auto Tire & Rubber Company and its Buffalo branch, and will continue the G. & J. agencies in both cities. The Berrodin Company is about to be incorporated.

"E. M. F.," Philadelphia.—Foss & Hughes, northeast corner of Broad and Race streets, have acquired the Philadelphia agency for the E. M. F.

PERSONAL TRADE MENTION.

W. J. Smith ("Rambler Bill," so-called from his long connection with Rambler interests in Philadelphia) startled the Quaker City "Automobile Row" last week by announcing his resignation as manager of the local branch of Thomas B. Jeffery & Co. He had been identified with that company for nearly fourteen years. Mr. Smith has signed a contract with the Maxwell-Briscoe Motor Company as district sales manager, with a distributing branch in Philadelphia and territory including Pennsylvania, Southern New Jersey, Delaware, Maryland, Virginia, West Virginia, Eastern Ohio, North Carolina, and the District of Columbia.

Martin Gillet Gill, Sr., one of the most prominent automobile dealers in Baltimore, Md., recently died of heart failure at his home on Ridgewood avenue, Roland Park. He was a member of the Motor Car Company, of which his son, Howard Gill, is the president. Mr. Gill was the owner of the first practical automobile to be brought to and operated in Baltimore. He also built and conducted the first auto garage in Baltimore, which was located on the site of the present motor car company at Maryland and Mount Royal avenues.

C. R. Mabley, who last year was manager of the importers' show at Madison Square Garden, and for many years identified with the automobile industry, is now associated with the American Motor Car Manufacturers' Association in connection with the show which opens in Grand Central Palace, New York City, on New Year's eve.

Richard Bacon, Jr., who, as manager of the Cleveland branch in Chicago, became well known to the trade, has been appointed sales manager of the Haynes Automobile Company, with headquarters at Kokomo, Ind. Mr. Bacon succeeds C. B. Warren who is now representing Stearns interests in Western territory.

Guy Vaughan, the well-known racing driver and mechanical expert of Wyckoff, Church & Partridge, New York City, will marry this week Miss Helen Knapp, a daughter of Mr. and Mrs. John A. Knapp, of New Rochelle.

A. N. Jervis, familiar to the trade as a writer of automobile topics, has again been appointed press agent of the automobile show to be held in Madison Square Garden under the auspices of the Licensed Association in January.

J. E. Garnett, of the Monarch Motor Car Company, who has been in charge of Wichita, Kan., branch, has been transferred to Kansas City, Mo., and R. R. Hayes appointed as his successor.

E. Percy Noel and Temple Emery, Jr., formerly engaged in automobile and trade journalism, have joined forces in the establishment of the Motor Press Bureau at 304 N. Fourth street, St. Louis, Mo.

C. F. Kimball, of C. P. Kimball & Co., Chicago, the well-known body-builders, is rapidly recovering from the recent illness which overtook him in Paris. He sailed for home September 26.

John Dorr, formerly with the Buick New York agency, is now assistant manager of the New York branch of the Everitt-Metzger-Flanders Company.

F. L. Thomas, who has been acting manager of the Franklin Company branch at 1450 Michigan avenue, Chicago, has been made permanent branch manager.

OMAHA HOUSE IN AUTO TRADE.

OMAHA, NEB., Sept. 28.—The Baum Iron Company, of this city, one of the largest and oldest concerns in the West engaged in the heavy hardware and carriage supply trade, has entered the automobile industry. It has just added to its business a new department, devoted exclusively to automobile supplies and accessories. At the head of the department is Eugene De Prez. Mr. De Prez is widely known to the motor car industry as the former secretary and manager of the Neustadt Automobile and Supply Company, of St. Louis.

The Baum Iron Company will give to its new department the advantage of branches in several cities and of a force of some 25 traveling salesmen, who will push the goods handled by the new department.

NEW TRADE PUBLICATIONS.

The Willard Storage Battery Company, Cleveland, O.—Electricity has occasionally been used for automobile headlights and sidelights, but hitherto always with carbon filament bulbs. The advent of the tungsten lamp now makes it possible to electrically light an automobile very economically, as this type consumes less than one-half the energy of the usual carbon lamp—that is, about 1 1-4 watts per candle-power to 3 to 3 1-2 watts for the carbon type. The filament in the low-voltage tungsten lamp is very strong and its shape is well adapted for use in automobile lamps; being made of heavy metal wire it will stand vibration without injury. Five sizes of tungsten lamp bulbs, ranging from 4 to 25 candle-power, are listed in the Willard Storage Battery Company's booklet, as well as two sizes of lighting batteries, three sizes for ignition, and a [illegible] wire, switches, etc.

Niles-Bement-Pond Company, New York City.—The results of fifty years' experience in the building of boring mills is shown in this catalogue, which describes the product of the Niles Tool Works, Hamilton, O. A dozen sizes of mills are listed, from the comparatively modest 30-inch size to monsters of 20-foot swing. The latter, of course, are hardly applicable to automobile construction. The small sizes are specially adapted to heavy chucking work and offer many advantages for the rapid production of duplicate parts. Many conveniences, such as quick-change positive gear feeds, automatic feed stops and quickly operating back gearing, have been provided for in the design. All parts have been proportioned to take full advantage of high-speed tool steels. The catalogue is illustrated by a large number of photographs of the various sizes and types of mills, and is a handsome piece of work.

The Winkley Company, Detroit, Mich.—Winkley oil hole covers and grease cups are known wherever automobiles are used and need no recommendation. A novelty, however, appears in the line of pressed metal grease cups. Many advantages are claimed for these over the ordinary types, as sheet metal permits lightness in construction with much greater strength. Castings are frequently spongy and are subject to flaws and sand holes. Pressed metal produces a perfect thread, both for the cap and for the stem. In placing them in position there is no danger of twisting off the stems and later no danger of their being broken off by accident while in use. The latest Winkley catalogue describes and lists these cups as well as the old lines of oiling devices.

F. A. Brownell Motor Company, Rochester, N. Y.—The Brownell automobile, marine and stationary motors are made in ten sizes of from 14 to 150 horse-power, with four, six and eight cylinders. There are two models, known as "plain top" and "overhead." The former has all valves in the head, actuated by push rods and walking beams from a camshaft in the usual position; but on the "overhead" type the camshaft is carried on the cylinder heads and actuates the valves directly. The Brownell catalogue describes and illustrates the various sizes and also gives a table of dimensions—a convenience many catalogue makers omit. The motors all appear to be solidly constructed and well adapted for heavy service.

Anderson Forge & Machine Company.—This company has just brought out a new catalogue containing over 500 detail drawings of forgings which are used in the automobile trade. They feel that this will help many manufacturers in their designing rooms and be a great time saver in making rough estimates for new work. A copy of this catalogue will be mailed to any manufacturer on request to the company in Detroit, Mich., or the National Sales Corporation, 296 Broadway, New York City.

Gram-Logan Motor Car Company, Bowling Green, O.—This company's folder gives advance information of three models of commercial cars—a three-ton truck, a one and one-half-ton truck and a delivery wagon. The large car is equipped with a 40-horse-power water-cooled motor and the two small cars with a 20-horsepower air-cooled one. Bodies are interchangeable, and several styles are carried in stock to select from.

National Brake and Clutch Company.—A new booklet has just been put out by the National Brake & Clutch Company, illustrating the many uses of the cork insert. They show cuts of fifty different ways in which the cork insert has been applied by them, and of special interest to the automobile user are their cork inserts for brakes and clutches as applied to the automobile.

New Goodrich Price List.—The B. F. Goodrich Company has issued its new price list of tires and rims for the year ending July 15, 1909. The company is also sending out with this new list a pamphlet, "The Light of the Glidden Tour," giving some of the experiences of the tourists who used Goodrich tires.

H. H. Franklin Mfg. Co.—This company has just issued its advance catalogue describing its 1909 models, the features including the auxiliary exhaust, concentric valves, spring suspension and transmission.

William F. Wright, Springfield, Mass.

The well-known vice-president of the Knox Automobile Company is an ardent autoist, and a driver of national reputation, having participated in several A. A. A. Tours for the Glidden Trophy.

INFORMATION FOR AUTO USERS

Auto and Yacht Fire Extinguisher.—Many occurrences are on record of serious damage being done to automobiles and yachts because of fires which might have been greatly reduced if the owners had had the use of some good chemical fire extinguisher. The Syracuse Chemical Fire Extinguisher Co., of Syracuse, N. Y., is selling a hand chemical extinguisher which it claims will instantly put out a gasoline or any other fire around an automobile. It has been designed especially for use on cars or yachts so that neither water nor rough roads can render it useless. Fig 1 shows the bottle holder which makes it unnecessary to run the risk of burning the hands while recharging, and takes less time. This company claims to have eliminated in this new model all of the unreliable and impractical features which many chemical extinguishers possessed. There is no loose stopper to become corroded, no bottle to break, or plunger to operate; any of which might render the extinguisher unreliable. The holder, shown in Fig. 2, being adjustable, can be readily fitted to any car or yacht.

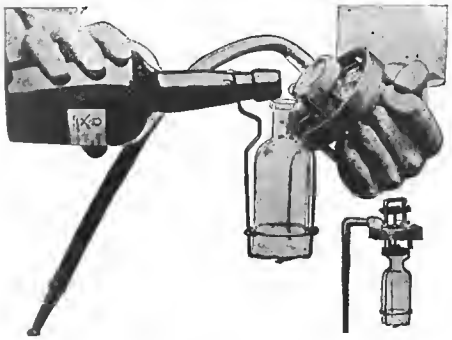


FIG. 1—SHOWING METHOD OF FILLING.

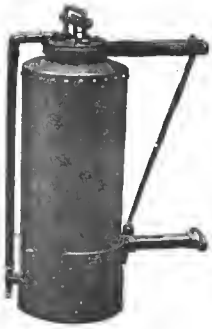

FIG. 2—EXTINGUISHER AND BRACKET.

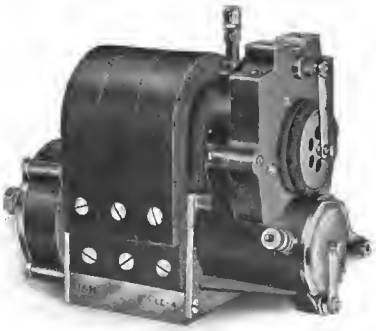
New Gasolene Can.—The Dover Stamping & Manufacturing Company, of Cambridge, Mass., has brought out an extra heavy galvanized can especially made for gasoline, which it claims has features making it very adaptable to the use of automobile owners. The distinctive point about this can is the facility with which the gasoline may be poured without spilling, as the spout is made purposely very large. A tight screw cap is not only provided on the top of the can, but one is fitted on the end of the spout to prevent evaporation.

NEW DOVER CAN.

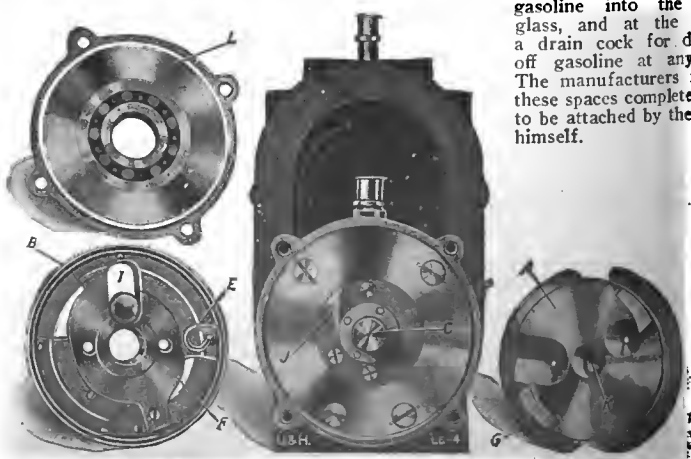
Unterberg and Helme Magneto.—The magneto shown herewith, manufactured by Unterberg and Helme, Durlach, Germany, is distinguished by a unique starting device which appears to obviate the difficulties often experienced in using a magneto without an accessory battery system. With this device, the speed of rotation for the necessary half-turn of the starting crank has no effect whatever upon the quality of the spark produced, and back-firing is made impossible by an automatic retard of the timing.

The illustration shows the starting device disassembled. *L* is the cover plate.



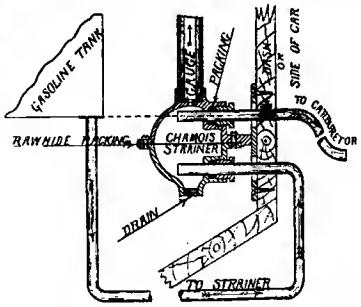
U. & H. MAGNETO COMPLETE.

A, the steel driving disc, has been slipped off of the armature shaft *C*, on which it is normally free to turn; the bronze disc *B*, secured to the armature shaft, has also been dismounted. This disc *B* carries a coil spring around its circumference, one end being attached to *B* and the other to a pin on *A*; thus *B* and the armature are forced to follow *A*. The steel ball *H* is loose in the slot *I*. This ball projects behind *B*, and, as *B* rotates, strikes the fixed cam *J*. The other side of the ball is held up firmly against the obstruction by the disc *A*, so that *B* is blocked and cannot turn further. *A*, however, continues to rotate, putting the connecting spring under an increased tension, until the radial depression in *A* comes opposite the steel ball. The ball immediately drops into the depression, freeing *B*, which turns with a sudden jerk until it catches up with *A* again. Of course, the armature is arranged so that the short, swift movement of *B* carries it over the sparking point, and generates as strong a current as if the magneto was turning at its maximum speed. The arrangement is also such that this sparking point is past the dead center of the crank. When the motor reaches a speed of 60 r. p. m., the ball is held by centrifugal force in the outer part of the slot *I*, and no longer engages the cam *J*. The drive is then direct and constant. The magneto itself is of the usual type with double armature winding, generating a high-tension current without the use of a separate spark coil. The timer, condenser and distributor are mounted on the rear end, and, with a few exceptions, follow the standard design. The "U. & H." magneto is handled in this country by the J. S. Bretz Company, Times Building, New York.



STARTING DEVICE OF UNTERBERG & HELME MAGNETO, DISASSEMBLED.

Gauge and Strainer Combined.—The Central Brass and Fixture Company, of Springfield, O., has placed on the market the Puritan combined gasoline gauge and strainer, which should be useful to owners of automobiles as a means of keeping their gasoline supply to the carbureter free from dirt and water, besides showing the driver at all times the amount of gasoline left in the tank. The gauge glass has a red ball which floats on the top of the column of gasoline showing the height in the tank at a glance, as the length of the gauge is made according to the depth of the tank on each car. In the sectional drawing is shown a general arrangement with gasoline connections made. This clearly shows the route of the gasoline from the tank, through the chamois strainer, and on to the carbureter. At the top of the strainer compartment is a small opening for the gasoline into the gauge glass, and at the bottom a drain cock for drawing off gasoline at any time. The manufacturers furnish these spaces complete, ready to be attached by the owner himself.



PURITAN GAUGE AND STRAINER.

VOL. XIX NEW YORK—THURSDAY, OCTOBER 8, 1908—CHICAGO No. 15

THE AUTOMOBILE

BRITAIN'S 4-INCH RACE WON BY NAPIER-BUILT CAR

DOUGLAS, ISLE OF MAN, Sept. 24.—The "four-inch" race, run off here to-day, was won by Watson on a Hutton car—a product of the Napier factory. Second and third places were taken by Darracqs, driven respectively by Lee Guiness and George. The three leaders all finished within five minutes.

This race was the fourth of the Tourist Trophy contests and is also, in all probability, the last road racing event to be held in the United Kingdom. Its name was derived from the fact that the cylinder bore was limited to 4 inches for a four-cylinder engine, and all the competing cars, save a touring Rover entered by its owner, have their cylinders bored out to the limit.

As might be expected, there is big variation in the lengths of stroke adopted; the smallest, 4¾ inches, being found on the Calthorpes, while the longest known stroke is the 7⅛ inches of the Darracqs. The reason for uncertainty in this last respect is that the stroke of the winning Hutton is not publicly known, but it is said to be between 7 and 8 inches. Curiously enough, the winning car was not considered to stand as good a chance as its two stable companions, which had several special features.

The winner's time was 6 hrs. 43 min. 5 sec. for the 340 miles, an average of 50¼ miles per hour. This may seem disappointingly low in view of the fact that some of the cars, and particularly the Huttons, have shown themselves capable of almost 90 miles per hour on a straight run, but it must be remembered that the Isle of Man circuit is not at all adapted for fast work and that its 38 miles includes 10 miles of climbing, 4 miles of which averages 1 in 10.

The dangers of the course for high speed work were well shown up in practice spins. Of the more serious mishaps, some five days ago the Coventry Humber ran off the road at a corner and the resulting damage was not fully repaired in time, thus preventing the realization of the excellent performance expected from this car. Similarly, much disappointment was caused by the overturning of Cupper's Metallurgique car on Monday last. The mechanic was badly hurt, but both Cupper and the car were patched up to run in the race. These Metallurgique cars, three of which were entered, are admittedly the most powerful in the race, and reliable power tests at the factory showed that the

One of the Most Picturesque Parts of the Isle of Man Course, Ballig Bridge, on the Way to Glen Helen.

Weighing-in the Arrol-Johnson, Driven by Resta.

maximum output touched 100 horsepower at 2,200 revolutions—surely an extraordinary power for so small an engine.

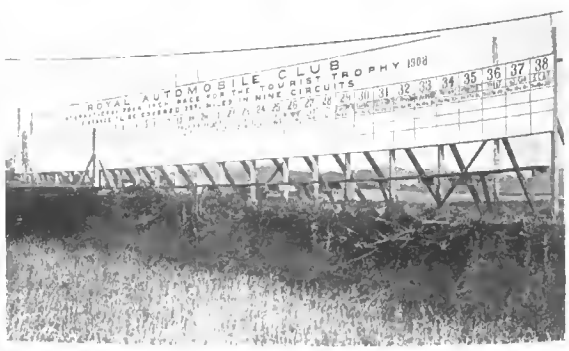
The weather to-day has been as good as could be desired, and the recent rains effectually laid all dust. Of the forty cars originally entered, the two special Rovers could not be completed in time, and the better of the two Thornycrofts was smashed up at Ramsey late last night. The two Berliets failed to materialize this morning, and hence but thirty-five cars faced the starter at Willaston at 9 o'clock. Of these cars, fifteen were foreign built and the remainder British. No American car was entered; in fact, the sole American entries in all four races were the two Whites which ran in the 1905 event.

Although numbered "2," Watson's victorious Hutton was the first to be sent off, for the touring Rover, which had been allotted first place, was by kind consent of its owner relegated to the tail end of the procession—so that it might cause as little obstruction as possible. At half-minute intervals the remainder were sent off, after which the big crowd settled down to watch for the first arrival.

Victorious Hutton Not Fastest on First Round.

Forty-five minutes after the start Watson came past, followed closely by the Arrol-Johnston, driven by Roberts, and Guiness'

General View of the Start and Finish.



Big Score Board of the Four-inch Race.

No. 20 Metallurgique Leading Past Hillsbury.

Darracq, the order of starting being maintained. The fastest time for this lap was made by George, whose Darracq averaged just 50 miles an hour. Subsequent laps showed an all-round increase of speed and the winner's average for the whole distance showed better than the fastest performance for lap one.

Of the unfortunates, Stirling quickly ran his Hutton into a wall at Ballacraine, luckily without personal injury; and in similar manner the Picard Pictet tried conclusions with the Quarter bridge. Fortunately this car was, like the majority of its fellow competitors, fitted with Rudge-Whitworth detachable wire wheels, and by fitting two new wheels and repairing a front spring, it was soon on the road again.

At the end of the second and third rounds Watson still held his own, but on the fourth lap both the Arrol-Johnston and George's Darracq finally managed to pass him after so long a struggle. The other two Arrol-Johnstons had both dropped out, one through engine trouble, and the second, driven by Resta,

with a seized-up clutch. Warwick Wright's Metallurgique was also withdrawn.

The end of the fifth lap showed that Watson had dropped back again to fourth place, Tuck's Beeston Humber taking third position. Seeing how matters stood, the Liverpool man did his utmost, and at the end of the sixth circuit had won back to second place, coming between Guiness and George on the so-consistent Darracqs.

Meanwhile the list of troubles had increased. Lewis's Deasy broke its crankshaft, but a new one was refitted on the road—though surely a crankshaft is rather an unusual "spare" to carry in a race. The De Dion made rather a bad début, and a seized-up clutch caused Stocks to give up at Ramsey. Both Beeston Humbers also withdrew.

No. 7 Metallurgique Pursued by No. 15 Hutton, the Winning Car.

At the commencement of the eighth lap Watson led, with the two Darracqs not half a minute behind. These three cars continually passed and repassed until, as the final round was commenced, it was seen, with great excitement, that George was two minutes ahead of Watson, who, in turn, had two minutes' advantage over Guiness.

At 3:44 a car was signaled and quickly Watson drew up at the finishing line—not yet certain of victory. The minutes passed and Guiness' Darracq arrived, nearly five minutes behind Watson.

George was still absent when the elapsed time had run out and Watson was declared the winner. Just as the result was posted up the missing Darracq roared up, taking second place, two minutes behind the winning car. It appears that at Glen Helen George found his carbureter on fire, and six valuable minutes were lost in repairing the damage done.

Although record time was made from this point to the finish, it was impossible for the Darracq to win back so much, and so, for a fourth time, a British car has been victorious in the Tourist Trophy race.

Truly George deserves to be called unlucky, for in the race of two years ago his Argyll finished second but was disqualified through loss of ballast on road.

The fourth to finish was the Calthorpe, driven by Porter—the lowest-powered car in the race—at an average of 46 miles an hour. The only others to complete before the time limit were the second Thornycroft and the Vinot.

THE AUTO CYCLE RACE.

DOUGLAS, I. O. M., Sept. 22.—The third annual race held by the Auto Cycle Club of Great Britain for a miniature of the Tourist Trophy, was won today by Marshall on a 3 1-2-horsepower Triumph. The competitors were divided into two sections, the single-cylinder class having 15 starters, and the multicylinder class 20 starters. A 16-mile course was covered 10 times. The winner's time was 4 hours, 4 minutes and 50 seconds, an average of 38 1-2 miles per hour. The race was singularly devoid of accidents. It is interesting to note that all the competing machines except three were fitted with high-tension magneto systems.

BRITISH TRADE TIRED OF RACING.

DOUGLAS, I. O. M., Sept. 23.—Two interesting races were on the program for to-day: the contest for the Henry Edmunds trophy over a 4-mile climb up Snaefell, and the Graphic trophy straightaway race of 5 miles near Foxdale. Both of these events were open to standard touring cars of power not exceeding 40 horsepower by R. A. C. rating, but as only four entries were received for each race the R. A. C. decided to cancel them.

The opinion, both of the general public and of the representative trade bodies, is entirely against the continuance of road events, whether in the form of races or of timed hill climbs, and hence it is extremely probable that to-morrow's Tourist trophy contest will be the last of its kind to be held.

Down This Homestretch Past the Paddock to the Finish the Drivers Made Their Grandstand Plays.

SIMPLEX SCORES IN BRIGHTON'S BRUTAL "24" HOUR

AFTER one of the fiereest fought struggles in the whole history of long-distance track racing, and most destructive to men and machines as well, a 50-hoursepower, four-cylinder Simplex, entered by the Palmer & Singer Manufacturing Company, and driven by George Robertson and Frank Leseault, evolved as winner of the 24-hour race promoted by the Motor Racing Association at the Brighton Beach mile course last Friday and Saturday. A 50-horsepower, six-cylinder Lozier, nominated by Harry A. Lozier and piloted by Michener, Mulford and Cobe, which won the 24-hour race run a fortnight before over the same course, was second. A 72-horsepower, six-cylinder Thomas Flyer, named by Harry S. Houpt Company, with Roberts, Salzman and Winters for its crew, finished third.

The three first cars all beat the previous world's record for a mile track of 1,107 miles, set up by Mulford and Cobe and the Lozier "six" in the former race—the Simplex, with a score of 1,177 miles and an average of 49 miles an hour; the Lozier, with 1,125 miles and 46.83 average, and the Thomas with 46.45 average. The following cars showed hour scores of 50 miles and over: Simplex, 57; Stearns, 57; Renault, 55; Lozier, 54; Zust, 53; Thomas "Six," 52; Fiat, 52; Cleveland, 50; Allen-Kingston, 50.

A 45-horsepower Renault, entered by Paul LaCroix and driven by Louis Strang and Charles Basle, the latter a racing pilot several years ago for H. L. Bowden's then famous Mercedes, figured prominently in the race for 17 hours, but was forced to retire the next hour owing to a broken connecting rod. It evolved as the one imminently serious disputant of the premiership of the Simplex in the race. It led, in fact, from the third to the twelfth hour, both inclusive, and incidentally took unto itself new records at all these points. At the end of the hour previous to its withdrawal it had a score of 851 miles, as against the previous record of 705 miles in 17 hours, with an average per hour of 50 miles.

In the battle of the tires, the Michelin carried off first honors, second place falling to the Continental, and the third car having for its equipment the Diamond.

Among those who like to see the honors of the racing game well distributed and perseverance receive at last its reward, the victory of the Simplex was a popular one. Charles A. Singer, its entrant, was warmly congratulated. He has been a liberal supporter of racing, but until this race had not landed the winner of an important event. The Simplex was originally the creation of Smith & Mabley. It has participated in one or more Vanderbilt Cup contests, and was a contender in the Briarcliff. Not a little of the ill-luck of the game, heretofore, has been its lot and kept from it a noteworthy victory. Its performance in the present race was most impressive. It ran like clockwork and seemed to have no end of speed.

Robertson and Simplex.

The performances of Louis Strang and George Robertson, who are to have prominent mounts in the Vanderbilt, the former on Paul LaCroix's Renault and the latter at the wheel of A. L. Riker's Locomobile, were closely watched. Strang lost none of the reputation he made as winner of the Savannah and Briarcliff cups by his consistent work, and Robertson displayed, in addition to his determined fighting qualities, a continence that he has not shown before and is highly encouraging for his future success at the wheel. George Salzman and Charles Basle, too, other Vanderbilt drivers, piloted their mounts in heady fashion. It was more than once remarked by those that witnessed Montague Roberts' magnificent stern chase of the Lozier that the Vanderbilt would be a gainer were he once more to be at the wheel of one of its cars. By way of a pardonable grandstand play, Barney Oldfield was at the wheel of the luckless Stearns for an hour or two. Barney, however, had done some long-distance driving before in the Briarcliff.

One fatality in the killing of a special policeman in the pursuit of his duty on the track and an unusual number of rather serious accidents to the drivers, marred the sport. In the third hour of the race, T. F. Fickett, a special policeman employed by the promoters, started to cross the track from the field stand to the paddock, some say in pursuit of some boys encroaching on the track. Four cars were approaching almost abreast from around the turn at the head of the homestretch. According to Robertson's immediate report of the affair to the officials, Fickett was first struck by him, then by the Stearns, and then by the Cleveland. He was taken to the hospital tent, where it was found that he had both arms and the right leg fractured, four ribs broken, and concussion of the brain. He died the next afternoon at the Coney Island Reception Hospital. Upon his death Robertson was placed under technical arrest, though not put in custody.

In trying to dodge Fickett, the Simplex swerved into the Stearns and broke the left front frame member. Pieces were sent for to New York and inserted so that the

patched-up car appeared again on the track early the next morning. The frame was further patched up to enable Oldfield to drive it for an hour or two on Saturday evening. The car had been making a good showing, holding fourth place in both the first and second hours, with scores of 50 and 100 miles.

Smashing of Machines Began Early.

The smashing of machines had begun, however, before the race had even started. At dusk following the afternoon sprints, several cars came out on the course for trial spins. The Garford had forced its way on the track against rules, so says Tom Moore, and was ordered by him back into the paddock. It turned and ran up the course toward the camp's entrance gate. Just then Michener, who was rounding the turn with the four-cylinder Lozier at full speed, ran into the Garford. The results of the collision made it impossible for either car to start in the races. The frame and rear axle of the Lozier were sprung and its left rear wheel torn off. Two wheels were smashed on the Garford and its frame was put out of commission.

A long list of mishaps followed to other cars and men that will bear detailing at once that the story of the race itself may be reached and told without such unpleasant interpolations. The accidents must be told, however, since they account for practically only half of the 12 starters in reality surviving the struggle to the end.

At the 190th mile, the Lozier with Harry Cobe at its wheel, was hit in the rear by a pursuing car. The collision turned the Lozier around and headed it for the fence; one beam broke the steering wheel, while another beam went between Cobe's legs, and through the cushion, dented the gas tank and bent the frame in front. In a couple of minutes Cobe was again under way, driving with but two spindles in his steering wheel.

Between 2 and 3 o'clock on Saturday morning there was a perfect holocaust of disasters. At 2:35 o'clock Renault, No. 14, with Julian Bloch at the wheel, at the first turn had a tire blowout, which hurled the car into the fence and upset it. The upset and a fire that resulted made of the car almost a heap of junk. Bloch was rather badly burned about the face in attempting to quell the flames. Five minutes later the Zust in trying to avoid the Renault wreck blew out a tire and ran into the fence opposite. It was so badly battered that a new front axle, a new wheel and a new radiator had to be put in. When it was thought to be ready to run, the magneto was found to be wrong, and the motor could not be timed.

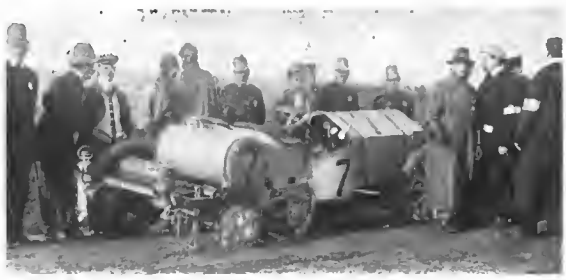
About this time the Cleveland also hit the fence 25 feet beyond. The fence rail passed through the radiator and the rear twin cylinders were so badly injured that a new motor and radiator had to be inserted. Then, after running for three miles, trouble developed in the transmission. A new one was put in.

The Fiat had to retire at 3:30 A. M., owing to the connecting rod breaking, through lack of oil. Practically the same cause put the Strang Renault out of the race, also with a broken connecting rod. The temptation to run without replenishing fuel proved fatal, it will be remembered, in the last race to the Allen-Kingston and the Simplex. Mr. LaCroix, however, says that the Renault's oil feed broke.

At 7:15 A. M. the Acme, at the upper turn, had a right rear tire blow out and skidded in the sand into the fence. It smashed a wheel and so deranged the motor that the car was withdrawn. At 8:15 A. M. the six-cylinder Thomas's right rear tire blew out and turned the car through the hole in the fence made by the Lozier. Though the post was cut off, the machine was not injured. Roberts jumped to the seat and relieved Salzman.

On Saturday afternoon the Garford, having replaced the entire rear construction broken in its collision with the Lozier before the race started, returned for a run to the finish, but soon had to retire owing to its clutch having burned out.

Toward the close of the race the hiatus of accidents was brought to an end by the Zust, whose pilot was T. W. Post, formerly connected with the automobile tire industry and known to the old cycle contingent as cycling editor of the Brooklyn *Eagle*. It ran into the fence on the backstretch. Charles Brown, the



Acme After Its Drive Through the Fence.

mechanic, was thrown out and had his arm broken. Mechanics and drivers of other cars, which dove through the fence, received scratches, cuts, and bruises that do not need cataloguing.

The race, though far bigger, finer, and more filled with thrills than the first one, was not the money winner that the initial meet was. The attendance at the curtain-raising sprints on Friday afternoon and during the early afternoon of Saturday suffered badly by comparison with that at the last meet. Nor was the opening night attendance nearly so large. The weather, however, had much to do with the latter, for an icy wind that chilled all hands to the marrow swept across the field from the north. Still there was a good, big crowd of six or seven thousand well wrapped in coats, sweaters, and furs on hand. On

Down and Out Renault Looked Forlorn.

Some of the Faces the Flashlight Revealed.

Robertson and Boys That Helped Him Win.

Saturday the weather moderated and a crowd of perhaps 12,000 saw the wind up.

The M. R. A. made noteworthy improvements in the excellent arrangements of the meet. There was much added lighting. A praiseworthy taximeter scoring system was installed that showed the standing of the cars at all times. Each car had its own board and scorer, the figures being changed by "spools." More beds than before were installed in the dormitory. It is respectfully suggested, however, to the management that in future admission badges to the "sleeping" room be confined to the officials and newspaper men, for whose comfort the dormitory was arranged at considerable expense, and that its privileges be denied to scorers and minor officials, made up largely of young men preferring a noisy night of fun to the sleep sought by the tired judges, timers, and scribes, rendered impossible by the noisy antics of the effervescent youths aforesaid.

On the pretense of awaiting repairs to the Garford that would make it possible for Mr. Hurlbert's car to compete, the start of the 24-hour race was delayed until 8:45 o'clock. At the shriek of the signaling horn, George Robertson made a quick jump and had sneaked across to the pole on the first turn with the Simplex before the other pilots knew just what had happened. He raced down the backstretch in the lead, followed by "Monty" Roberts in the Thomas "Six" and Laurent in the Stearns. This trio not only finished the first lap in this order, but kept it for 5 miles. Then Roberts sprinted to the fore and led at 10 miles in 11:32. In the early sprinting, however, the Simplex had been showing miles in 58 seconds. Roberts led at 20 miles, also in 22:23. Then Robertson went to the head and got a firm grip on the lead, and in the meanwhile Strang had worked through the ruck into second place. The simplex made 25 miles in 27:33 and 50 miles in 54:31.

Order at End of First Hour

The order at the end of the first hours was: Simplex, Strang, Lozier, Stearns, Roberts, Fiat. The same order exactly ruled at the end of the second hour. There was a gap of 12 miles between the leaders and the pursuing bunch. Thus early the chaff had been winnowed from the wheat, and the likely leaders separated from those with but one or two exceptions with any chances of figuring otherwise than as mere "also rans" in such fast company as this pacemaking sixtette.

The promises of a knockout pace that should dispose of the weaker brethren early in the struggle were, indeed, being fulfilled. Robertson set a terrific clip with the Simplex, 55 miles the first hour and 107 the second, as against 52 and 101, the former figures. All this time Strang was hanging on like grim death with the Renault, with the record-holding and victorious Lozier chasing swiftly at their heels.

In the third hour Strang went to the fore, and the Lozier got by the Simplex also. The next hour, however, the Simplex became the runner up and "Monty" Roberts supplanted Mulford as pursuer. It was a stubborn all night and early morning struggle with the Renault setting the pace for the Simplex, and the Lozier and Thomas alternating as pursuers. In the fifth hour the Fiat had forced itself into third place, and was beginning to look dangerous, when its connecting-rod calamity came and put it out of the running.

The thirteenth hour proved a luckless one for Strang, for while the Renault was in camp, the Simplex secured the lead that it never lost to the finish. From that point on the French car got no nearer the American machine than 3 miles; was at times 10 miles behind, but, as a rule, but five measly little miles to the bad that a stop for a tire or oil could wipe out.

The excitement of the race between Renault and Simplex and Strang and Robertson was at its height, when the Renault, in the eighteenth hour, turned into the paddock and word came that its connecting rod had broken and that it was out of the race altogether. The disappointment of the crowd was keen and the sympathy for the popular French sportsman was general. Then attention was turned to an equally stubborn duel that was in progress between Michener and Mulford in the Lozier and Roberts and Winter in the Thomas for second and third money, for Robertson had an hour margin and only had to keep up a

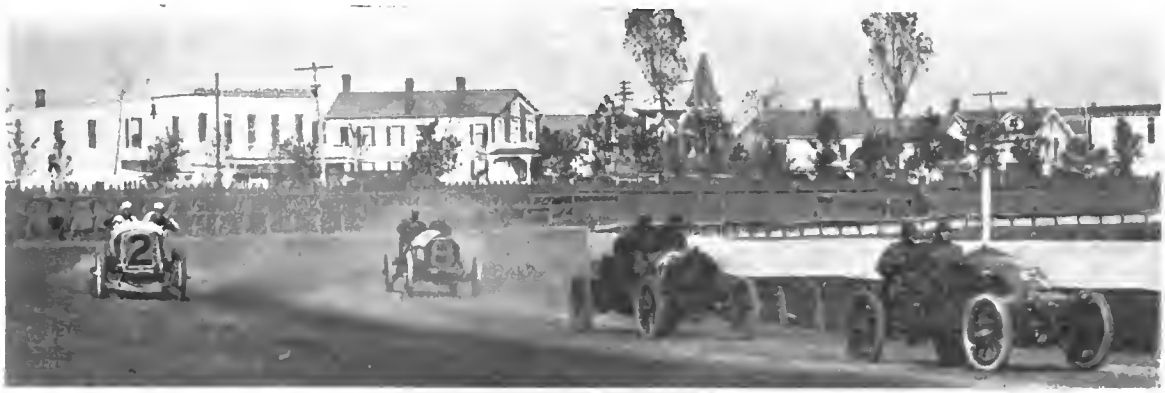
Taximeter Boards Showed Each



Renault Leading Simplex Into Homestretch Pursued by Thomas on the Pole and Lozier Outside.

fairly fast clip and take no chances to win out comparatively easy. This he did, but with the exit of the Renault and the slowing down of the Simplex all hopes of a 1,200 miles score and a 50 miles an hour average were abandoned. Up to the withdrawal of the Renault the pace set had been a bit faster than a half century an hour.

Roberts in endeavoring to close the 10-mile gap that separated the Thomas from the Lozier furnished the excitement of the wind up. His game chase made him a favorite with the crowd. Roberts got as close as four miles to Michener in the twenty-third hour. It was this desperate sprinting to catch up, however, that put him ahead of the old figures and in the trio of record breakers. A half an hour before the finish the referee ordered the Stearns and Zust off the course under the rule permitting the barring of contestants that had no chance to win and might interfere with or endanger the other contestants.

"Barn-Stormers" Won Short Events.

The feature race of Friday afternoon's curtain raising program was the 50-mile free-for-all. It had for starters the Barney Oldfield-Charley Soules combination, driving six and four-cylinder Stearns stock cars, respectively; Harry Kirkpatrick, Hotchkiss; Harry Roux, Mercedes; Steinwitz, Mercedes, and Ray Howard, Palmer & Singer. It was an easy one-two win for the "barn-stormers" and the Stearns, Barney winning in the excellent time of 50:42, with Soules second in 51:34 4-5; Roux third in 52:06, and the Palmer & Singer fourth in 54:46.

That Oldfield had lost none of his popularity with New Yorkers was evidenced by his cordial greeting when he appeared with a linen duster, the inevitable cigar, and his Stearns "six" to face the starter for the five miles for six-cylinder cars. He greatly pleased the grandstand by making a runaway of it by a quarter of a mile in 5:20 2-5, despite the fact that he mistook the checkered last lap banner for the finish flag and had to be told to go on when he slowed down. His time for four miles was 3:52. Harry Kirkpatrick in a Hotchkiss stock car was second, and Ray Howard in a Palmer & Singer third.

The Fiat pair had a try against Christie's mile track record of 54 seconds. George Robertson, in the Tornado, scored 58 seconds and Ralph De Palma succeeded on the Cyclone with a mile in 52 2-5 seconds. In a match between these two at 10 miles, the Cyclone was cut loose and won in 9:45, the Tornado having stopped in the fourth mile owing to a broken gasoline lead.

PENALIZATIONS FIRST DAY OF CHICAGO RUN.

CHICAGO, Oct. 6.—The 1,000 miles four-day reliability test of the Chicago Motor Club started this morning, and at the close of the first day's run of 262 miles over the Kenosha-Janesville-Rochelle circuit thirteen of the seventeen contesting cars still had perfect scores. Of the four that were penalized, the Maxwell two-cylinder touring car experienced cabureter trouble, water getting into the mixture, which cost 24 points to correct. The No. 3 Mason was penalized 66 points for oiler trouble, while the Studebaker touring car lost a pin out of its differential, causing it to be laid up at Janesville. Its penalty has not as yet been announced, but it is the intention to start again to-morrow. The Reliable Dayton buggy had not reported at a late hour to-night. The other thirteen cars have perfect scores as follows: No. 4 Mason, Apperson Model O, Midland, Pierce Arrow roadster, Haynes roadster, Premier roadster, Rainier, the two Whites, Franklin, Haynes touring car, Marmon, and Pierce Arrow big six touring car.

Two of the entrants were scratched, the Knox because of not having a driver and the Premier touring car because it did not arrive in time from Kansas City.

BAY STATE ENDURANCE TIE FINALLY CALLED A DRAW

BOSTON, Oct. 3.—The endurance test of the Bay State Automobile Association, which started as a twenty-four hour endurance run, but which developed into a contest of over 1,600 miles and the hardest test ever given motor cars in this country, was concluded Thursday evening when the three cars, which for eight days had survived every task set for them and had retained perfect scores to the end, were withdrawn by their owners with the consent of the committee.

These cars are the Franklin and Studebaker tourers and the Shawmut runabout. The Franklin was driven by Carris of Transcontinental and Glidden tour fame, and Burns; the Studebaker by W. G. Jones, and the Shawmut by Harold Church. When they were withdrawn they had covered 1,607 miles without an adjustment, repair, or replacement, and had made every control on time, their scheduled running time being about ninety hours and their actual running time considerably less. Having given this demonstration of reliability, the owners of the cars, the Franklin Automobile Company, Studebaker Automobile Company, and Shawmut Motor Company, respectively, felt that it was useless to continue the contest, as the cars were in first-class shape and apparently could keep on indefinitely. The committee had already set up the running schedule to the limit allowed by law and had selected as bad roads as it was possible to find, including mountain grades, sandy and rough going; the cars had been driven in blinding dust and in thick mud, and there seemed nothing more within reason that they could be called upon to accomplish.

Of the twenty-one cars that started, sixteen were penalized, but the penalties in only five cases can be chargable to structural or mechanical trouble. In the other cases such things as dust clogging the carbureter, gasoline failing to feed on a long hill or owing to the position of the cars caused motors to stall and points to be scored against the machines. Two cars were put out by broken wheels, one of the Overlands suffering this misfortune near the end of the original run, and F. E. Wing's Glidden tour Marmon being put out by this mishap in Monday's run-off to Portland and return. The Stevens-Duryea went down because of a leaky gasoline connection, and the Chalmers-Detroit had transmission trouble. The Oldsmobile broke a spring in the first run-off. The Pierce and the Fosdick Lancia were eliminated by failure of the gasoline to supply the carbureter owing to the angle at which the cars happened to be standing, and the Hilliard Lancia and the Rambler were penalized for stalled engines due to dust in the carhureter. Two Overlands and a Buick did not finish the first day's run, and another Buick was put out of business by a collision with a horse. The Cadillac and the Corbin were late at controls and lost points in this way, the lateness being caused by the drivers losing their way in the dark. The Shawmut touring car was also scored against for lateness, the car having been stuck in sand. The Buick and Reo runabouts, which finished perfect in the original run, did not participate in the run-off.

The trophy has not yet been awarded, and ways and means are now under consideration for properly recognizing the merit of the three machines which went through with perfect scores.

Preparations are complete for the great balloon race for the Gordon Bennett trophy, which will be held in Berlin, Germany, October 11, under the auspices of the Berlin Aero Society. It is expected Emperor William and the Crown Prince will be present.

HORSE-POWER RATINGS OF AUTOMOBILE MOTORS*

By THOS. J. FAY, President Society of Automobile Engineers.

IN finishing cylinders, if the stroke is great, the bore will be conical, since finishing to a considerable depth in a blind hole evolves conical results. Many claim to be able to finish to a fraction of a thousandth, even if the stroke is very long; doubtless they can, but not at a cost allowable in practice. There are a large number of parts in an automobile, and the cost of the finished product must be very low in comparison. The design of each part must be such that the work can be done by men available in the open market. Leakage is more of a detriment in the long stroke motor, because there is more time in which the mixture may escape. If the long stroke motor is more difficult to finish, the chances of leakage are greater. It follows, therefore, that the initial (apparent) advantage is, to some extent, at any rate, a theory. It is not the purpose here to make predictions, but to call attention to the two sides of the matters to be considered by the designer before he commits himself, especially in view of the fact that once the design of a motor is crystallized, it is then too late to make any substantial change.

Regarding Torque vs. Speed.

For a given horsepower, the motor in which the torque is a maximum should prove the most attractive, for reasons as follows:

(a) It will then be the more difficult to "stall" the motor.

(b) The motor will run slower without "laboring."

(c) The motor will start with a greater load at a slower speed.

(d) The motor will be more capable of extracting the car out of high resistance portions of the roadways.

Torque is the product of piston area times mean effective pressure; horsepower is the product of torque and speed. It is plain then that piston area is of the greatest importance, under such conditions, and even if the stroke is short, the torque will not diminish until the speed is quite high, whereas the advantages enumerated are all with the lower range of speeds where the effect of diminishing torque will not be noticed.

As between a short-stroke motor with a considerable piston area and a long-stroke motor with a diminished piston area, the short-stroke motor is the superior of the two in automobile work from these points of view, at any rate. For the same power, the short-stroke motor must be of the greatest piston diameter, hence of the maximum torque (at the lower speed range). If the bore of the short-stroke motor is greater for a given power, then the valves can be of greater area and the mixture losses will be a minimum.

The result is, all things considered, that the long-stroke motor shows its disadvantages only where the bore is the same for both, and the author is not in a position to make the k values in his formula differ, in view of a difference in stroke, on a basis as shown in the curve, Fig. 1, since designers are not compelled to accept the conditions there set down, i. e., the same bore for both the long- and the short-stroke motors, considering a given horsepower rating. One point more: torque is not limited by speed, as we are accustomed to regard it, unintentionally perhaps, although the torque does diminish as the speed increases. It is the tortuous passages and the obstruction offered by the valves that does more to suppress the torque than any other influence. Were the valves of the same area as the pistons, and the manifolds so short and straight as to offer no appreciable resistance to the flow of the gases, the torque would remain nearly constant at all speeds. On the other hand, it is the automobile that makes the least noise, that is the most desirable. If the valves are quite large, have strong springs, and the compression is good, speed and noise are then companions. Noise, in itself, is rather a bad phenomenon, for the very good reason that the mechanical losses in machinery are indicated by heat and noise.

There is a limit to the sizes of the valves then, hence the torque will fall off at the higher speeds, not because of the speed *per se*, but for reasons incident to the construction of the valves. On the other hand, there are limits of speed, one of which is the diminishing torque, another being the ills of the inertia component. Were it possible to so design a motor as to eliminate the weight of the moving parts, there would be no limit to the speed on that account. The speed would still be limited, however, by the falling torque, due to the inability of the explosive mixture to follow quickly receding pistons. The largest valve diameter found in practice is one-half the diameter of the piston, while the smallest equal one-quarter the piston diameter. This is a vast difference in practice, if we but take into account the fact that the area varies as the square of the diameter.

Influence of the Valve Lift.

If a valve lifts the equivalent of one-quarter of its own diameter (flat seat), the area of the opening will be approximately equal to the area of the valve, while if the valve is half the piston diameter, its area will be equal to one-quarter the piston area. But valves do not lift the equivalent of their own diameter, nor are most of them flat-seated. The actual lift is seldom more than ⅛-inch, at the most. The larger the valves, the more the lift is diminished to obviate noise, so it would seem the available space through which the mixture must "sift" is but small, indeed. Fortunately, the mixture is under pressure, or impelled by a vacuum, which amounts to the same thing. The exhaust is under pressure (terminal pressure) and in the four-cycle motor the piston sweeps the gases out. These are matters that influence the torque, hence the horsepower rating, and, it is more to the point to give them close attention than it is to browse over formulæ, with a view to predicting the probable commercial rating of a motor; it is the motor that must deliver the power rather than the formula. The time the valves are open is also of the greatest importance, no less than the relations of opening and closing to the travel of the piston. If the valves are small in proportion, and the lift limited, to afford the best possible results, the time of actual opening is the only remaining loop hole through which the designer can mount to success. An inlet valve, for illustration, should open at the beginning of the suction stroke, and should remain open until the piston compresses the mixture sufficiently to render the sum of the opposing pressures equal to zero. On the other hand, the exhaust valve should open toward the end of the expansion stroke (not at the end), at the point where to be rid of the exhaust gases is of greater importance than the balance of the work represented

*Continued from page 467 of "The Automobile," October 1.

CORRECTION.—On page 430, issue of THE AUTOMOBILE, September 24, the last bracketed part for the horsepower formula, reads:

$$\left(\frac{H.P. \times 33{,}000}{2\pi R P}\right)$$

It should read:

$$\left(\frac{H.P. \times 33{,}000}{2\pi R S}\right)$$

The equals sign in the formula for R is incomplete. As printed it reads minus.

On page 465, issue of THE AUTOMOBILE, October 1, the horsepower formula (Prony brake) reads thus:

$$H.P. = \frac{2RSP}{33{,}000}$$

It should read:

$$H.P. = \frac{2\pi RSP}{33{,}000}$$

T. J. F.

by the terminal pressure. The exhaust valve should stay open as long as possible, which is up to the time of the inlet's opening.

Few, indeed, are the motors in which this question is so thoroughly disposed of as to require no further attention. The timing of the spark is also open to investigation. As the speed increases, the spark must be advanced, else the propagation of the flame will be ill timed, the mean effective pressure will be lowered, and the power of the motor will be reduced, as indicated by a falling off of the torque.

Fig. 3 shows the phenomenon due to late spark, in which it will be observed the pressure not only fell off, but the flame propogation was delayed. This decreases the power, in that the torque will be much diminished. When this condition obtains in a motor, it is persistent, and, as a rule, due to defective equipment, so that the operator is rarely able to so "tune up" as to eliminate the defect; the sparking equipment is more likely not what it ought to be.

Harmonizing the Car and Its Motor.

There are two conditions to be satisfied as respects the motor in conjunction with the car. The motor must be equal to the occasion when the car is running at its maximum speed, and it must have sufficient flexibility to enable the operator to run the car at speeds below the maximum Involving the maximum

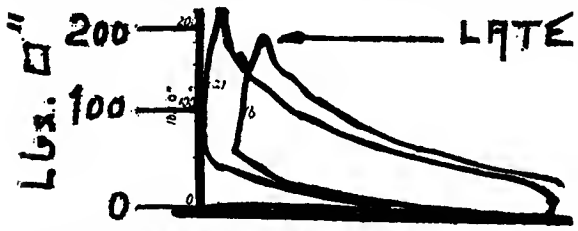

Fig. 3—Showing a late spark resulting in a reduction of torque, hence of power as well. (This drawing was originally the work of W. Watson, presented in a paper before the Royal Automobile Club of Great Britain, February 21, 1907.)

speed, the gear ratio must be that which will end in a zero equation, if the power of the motor is indicated, plus the resistance of the car. This is not always so, and the result is the motor is not allowed to do as well as it really could under better conditions.

If the — horsepower of the car equals the + horsepower of the motor, the gear ratio will be the ratio of the crankshaft to the driven wheels of the car when the car is moving as fast as it can impelled by the motor delivering its highest power. Taking this as a statement of fact, it is easy enough to devise a formula to satisfy the conditions of a zero equation.

If we say $-\text{H.P.} = \dfrac{2\pi R' S\left(\left(\frac{33{,}000}{88}\right)\left(\frac{H.P.'}{Q}\right)\right)}{M \quad 33{,}000}$, in which:

$-H.P.$ = the resistance offered by the car in horsepower.
R' = the radius of the driven wheel in feet.
S = the speed in r.p.m. of the driven wheels.
Q = the mechanical efficiency of the transmission system.
M = the speed of the car in miles per hour.
*$H.P.'$ = (in brackets of the formula) the horsepower as measured at the contact of the tires and road bed.

The (plus) horsepower of the motor must equal the requirement as above set down, and for convenience, it will be well to distort the same formula, with a view to deriving the horsepower of the motor, thus:

$$+H.P. = \frac{2\pi RSP}{33{,}000}, \text{ in which}$$

$H.P.$ = the actual delivered horsepower of the motor.
R = the radius in feet = unity.
S = the angular velocity of the crankshaft in r.p.m.
P = torque.

*H.P.' includes wind resistance. This horsepower, plus the loss in transmission, must equal the horsepower of the motor, as measured by a dynamometer.

By way of an example, it will be something to set down the known values before arranging them, thus: $\frac{33{,}000}{88} = 375$

$Q = 80$ per cent; it may be higher or lower in different cars, but the value taken will serve in general.
$2\pi = 6.28$.
$R' = 1.5$; R' depends on the sizes of wheels used on cars; in this case 36-inch wheels will be taken.
$S = 560.5$ revolutions per minute, for 60 miles per hour.
$H.P.' = 36$.

With the known values thus available, it will be an easy matter to insert them in the formula and solve for horsepower thus:

$$H.P. = \frac{6.28 \times 1.5 \times 560 \times \left(\frac{375 \times \left(\frac{36}{80}\right)}{60}\right)}{33{,}000} = 45.$$

For the motor we would have:

$$+H.P. = \frac{2\pi RSP}{33{,}000} = 45 \text{ horsepower, in which}$$

$2 = 6.28$.
R = unity = 1 foot.
$S = 1{,}120$.

$$P = \frac{45 \times 33{,}000}{6.28 \times 1{,}120} = 206.8 +$$

The gear ratio would have to be as 560 : 1,120, or as 1 : 2, in order to permit the motor to run at its best speed with the car making 60 miles per hour. Any other gear ratio would defeat the plan, whether up or down, since there would be only one speed at which the motor would deliver its maximum power, which it would have to do to equal horsepower = 45.

The second condition to be satisfied takes into account the flexibility of the motor, in order that the car may run at less than the highest speed the motor is capable of dictating, under conditions of a correct gear ratio. This second condition is rarely, if ever, satisfied in practice, for if it were there would only have to be one set (couple) of gears in the transmission. In practice it is considered the highest attainment if the motor will enable the driver to negotiate all road conditions on the high gear. The maximum flexibility of the motor would then be in evidence and this would be a condition, induced by a motor characteristic showing increasing torque with decreasing speed.

Some General Motor Considerations.

Here is evidence of the desirability of a motor of maximum bore and minimum stroke. The torque would tend to hold in proportion to the square of the bore and would recede with the speed, after a certain speed is attained. Of course, on the boulevards, flexibility would be assured, irrespective of the shape of the torque curve, since the torque would not be lower at the lower speeds than that of the highest power speed. The car takes power greater than in direct proportion to speed on a given level road and this fact would assure flexibility on good level roads. It is when it becomes necessary to go slower in bad roads that the higher torque is a necessity and it is the motor with the maximum bore for the power that will be the most likely to favor this road condition.

Thus far it has not been necessary to specifically consider the number of cylinders best suited to the problem. Indeed, it is a fact that the abstract question is independent of the number of cylinders. In practice, however, it has been found that the weight efficiency is influenced by the number of cylinders. It is purely a matter of weight efficiency then that influences the cylinder question, barring the matter of the space available plus style and trade considerations. As a purely engineering proposition, the number of cylinders to use will be the number that will afford the highest weight efficiency, coupled with a practical thermal efficiency. There is no chance of any motor, of any number of cylinders, being superior merely because it has so and so many cylinders. The "I-saw-it-first" idea is not an engineering proposition at all, nor can it have any bearing on the situation in the long run.

If a single-cylinder will suffice for the purpose, it is the best to adopt, but if it will not, then to use two cylinders would be the natural sequence. Should the situation demand more than two cylinders, it is to four that one should look, then to six, and finally to eight. With a single-cylinder motor must be included a flywheel of a weight capable of completing the cycle, and when the excess of flywheel weight amounts to more than the second cylinder, it is the two-cylinder motor that is wanted. Likewise, as the power requirement is advanced, the conditions naturally indicate more cylinders.

As the number of cylinders increase, the torque impulses are multiplied, and as they spread around the circle, the need of flywheel effect gradually recedes until with enough cylinders the flywheel ceases to be of value, except while the motor is being started, during which time the flywheel serves a useful purpose, since the initial effort, in the absence of any flywheel effect, would be beyond the average motorist. To entirely do away with the flywheel, neglecting the question of cranking, is a matter not worth discussing, because more than eight cylinders would be required and the author is willing to go on record as responsible for the prediction against the chances of any one ever wanting a greater number.

The argument in favor of a plurality of cylinders is as simple as can be. A ship will make headway in a steady wind that cannot be made in a series of gusts of wind. It will stand up under all the air that goes to make a hurricane if delivered at a steady rate, but not otherwise. Likewise, the mastery of the energy stored in the fuel is best managed in small increments, multiplying the number of impulses to the maximum, bearing in mind that complicated mechanisms are to be avoided, when possible to do so. It would be vain to jump to the conclusion that this simple way of viewing the matter argues for multiple cylinders at once and for all. The facts are quite opposite. If in a multiple cylinder motor certain sizes of cylinders will serve the purpose well, any less number of cylinders of the same size will serve the purpose equally well if power requirement is reduced in direct proportion to reduction in number of cylinders.

As the number of cylinders is reduced, the flywheel effect must be increased, and the proper guide is the weight efficiency on roads such as America affords; in lands where fuel is high and road making has been advanced, it is the thermal efficiency that should remain uppermost in the mind's eye of the designer. It might be said a single cylinder could be so large as to preclude the chance of rendering the motion steady, which would be quite true in the absence of enough flywheel effect to complete the cycle within the limits of "speed fluctuation," called steady when referring to a motor with a plurality of cylinders.

There is no device available that will so readily and so evenly part with its energy as a rotating mass in the form of a flywheel. Overlapping impulses, as in a multiple cylinder motor, is a crude device in comparison with flywheel effect. The disadvantage of the flywheel lies in the weight required to do the work, and weight efficiency is of such great moment as to preclude the use of sufficient mass to render it feasible to use cylinders large in bore and small in number beyond certain limits.

Some single-cylinder cars are not as steady as cars with multiple cylinders, but only because the flywheel effect is inadequate for the purpose. In such cars, the flywheel weight is stinted, and properly so, since the cars are heavy enough as they are. They merely emphasize the question of the desirability of weight efficiency.

[In later issues, the influence of the carbureter, the fuel, and the electrical problems entering into the subject will be separately discussed.]

S. A. E. TO MAINTAIN EMPLOYMENT BUREAU

AMONG numerous other activities, the Society of Automobile Engineers will henceforth maintain an information bureau for the mutual benefit of members seeking positions and of the manufacturers in need of additions to their technical staffs. As a matter of fact, American automobile manufacturers are now very largely represented in the membership, so that the innovation will result in benefiting members both ways. The names and qualifications of those seeking new positions will be kept on file, as will also the needs of makers desirous of filling vacancies in their engineering departments, or of employing additional men, and both will in future be published in the quarterly transactions of the Society.

In view of the peculiar status of the automobile industry where a supply of competent technical help is concerned, due to the extremely rapid growth of automobile manufacturing in this country, there is little doubt that this move on the part of the Society should meet with the approval and support of the industry as a whole. With the active co-operation of manufacturers, whether members of the Society or not, and of those members who are interested in this, there appears to be no reason why it cannot be put on a practical working basis in a very short space of time, and the results will undoubtedly be of a nature to benefit all concerned, as well as to increase the already rapidly growing influence of the Society of Automobile Engineers.

AUSTRIA'S AUTOMOBILE TRADE FIGURES.

The Austrian Chamber of Commerce has just published the statistics for the first six months of 1908, which show a general improvement, both in the import and export trade, the former being especially on the increase. The figures for the period stated are 5,575,180 kroners this year, as against the same time in 1907, when the value of goods imported came to 3,260,400 kroners. Germany leads the way in cars de luxe, commercial vehicles and engines, supplying 141 of the cars to France's 90 and Italy's 64. The remaining 22 are divided between the United States, England and Switzerland. The German Empire imported 14 commercial vehicles and 74 motor cycles into Austria.

The export trade shows figures to the extent of 1,930,750 kroners, a rise of 242,650 kroners in comparison with the first half of 1907. No business was done with the United States as far as cars are concerned, Germany again being the best customer, but four motor cycles were forwarded to America. The motor cycle export shows an astonishingly small total, only 80 in all, and yet cycle building is one of Austria's strong points.

SPECIAL LOCOMOBILE FIRE FIGHTERS.

BRIDGEPORT, Conn., Oct. 5.—They are now building at the Locomobile factory no less than three special fire-fighting automobiles for service in various New England towns. One of these is a hose-wagon for the town of Waterbury, Conn., designed to have a capacity of 1,000 feet of 3-inch hose beside its crew, and a second is to be a combination chemical extinguisher, ordered for service in New Bedford, Mass. Both are being built on the regular 40-horsepower Locomobile chassis with special bodies designed to fit the requirements of fire-fighting service. A most unusual feature to be found on them is the fitting of 40 by 6-inch Fisk tires on the rear, and 40 by 5½-inch tires on the front wheels, the equipment being the same in each case. The third car is being built for the city of Bridgeport, which already has several cars of the same make in its fire department.

As the Austrian Emperor has just given his sanction, the Austrian motor liability law will come into force November 1. This measure will have a grave bearing on the home industry.

USEFUL THINGS FOR THE AUTOIST TO KNOW

A LOW-TENSION magneto of early type may frequently be considerably improved by rewinding the armature with fine wire to give a higher voltage when cranking. The following directions will apply to such a case, and also to rewinding when the armature coil becomes damaged. In case it is desired to wind with

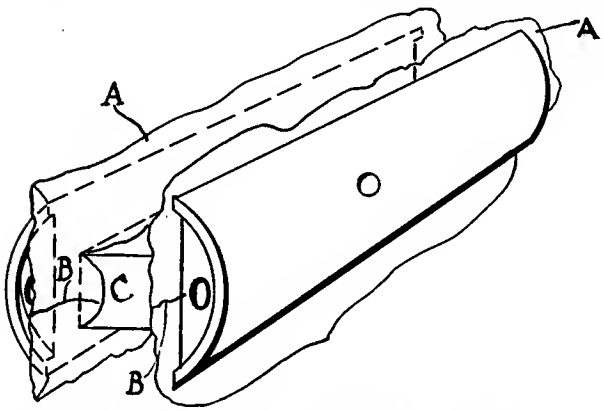

Fig. 1.—Showing the first step in insulating A A, pieces of muslin, cut to B B to enable them to be slipped over core. C, central body of core.

smaller wire, the wire already on the armature should be stripped clean of insulation and calipered with a micrometer to determine its size. If it is an even size—28 or 30—it is probable that the next smaller even size will be suitable. The new wire should not be less than half the sectional area of the old, and about two-thirds more will probably be right. After the old wire has been stripped off, new insulation will be necessary next to the core. Fig. 1 shows the first step in insulating. First the inner end of the wire is soldered to the core, and then pieces of muslin, A A, are slipped over the core, being cut at one point, B B, to enable this to be done. Three such pieces are put next to each pole, with the cuts B coming alternately at opposite ends. Next a strip of muslin slightly wider than the core is wound tightly three or four times around the central body C of the core. After binding it with thread all the muslin is shellacked.

The winding process is best done in a lathe; see Fig. 2, in which the dotted lines indicate the dead center. The core is rotated backward, by crossing the lathe belt if necessary, and the wire is wound as smoothly as practicable, like thread on a

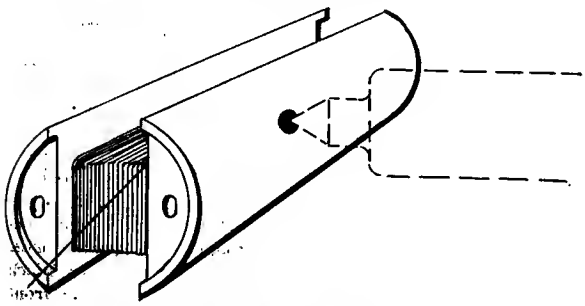

Fig. 2.—Showing the winding process with use of lathe. Dotted line indicates the dead center.

spool. To hold the wire while it is being wound on, take a piece of cloth folded three or four times around the four fingers of the hand, and give the wire a loose turn around the cloth. If the armature is unprovided with centers these can easily be supplied. At intervals stop winding and hammer the partly completed coil flat by a block of wood and a light hammer. When the coil is completed twist the outer end two or three times around the next turn to prevent it from flying downward by centrifugal force—see Fig. 3. Next the whole coil is bound with thin, hard brass wire wound into the shallow groove turned in the armature poles for that purpose. Under this wire binding, next to the coil, is an insulating strip of mica A, Fig. 3, and a thin strip of copper—commutator copper is best—B is slipped under the binding wire and its ends doubled over to prevent the brass wire from spreading. The piece B and the wire binding are soldered at several points, and particular care is taken to solder the ends of the binding wire fast. When this has been done the final operation is to saturate the coil thoroughly with shellac, giving it all it will take, and baking it for several hours in an oven.

It is essential that the binding wires be drawn as tight as possible. This is best accomplished by replacing the armature shafts and centering them in a lathe, after which tension may be put on the binding wire as it is wound on by running it between two fibre blocks squeezed together in the tool post.

Strong Spark for Carbureter Adjustment.

When a new carbureter has been put on an engine it is sometimes difficult to get the mixture near enough right to start the engine, which is obviously the first step in obtaining correct adjustment. This may be particularly the case when ignition is by an old-style magneto, since these frequently do not generate a sufficient spark unless the motor is cranked quite smartly. If the ignition is by make-and-break it is easy to disconnect the

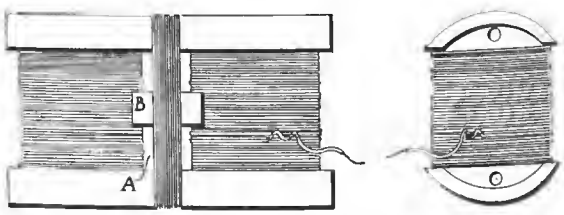

Fig. 3.—Showing method of fastening wire to prevent flying downward by centrifugal force.

magneto and substitute a battery and gas lighting coil. It is only necessary to disconnect the wire from the switch to the bus bar to which the ignitors are connected, and connect the battery wire in its place. Six or eight fresh dry cells and a coil will give a hot enough spark to ignite almost anything. The negative terminal of the battery is, of course, to be grounded. It does not take much running to exhaust the battery, therefore the magneto should be switched in as soon as the engine starts.

Possible Cause of Knocking.

Knocking, which occurs once per revolution or every other revolution in an engine whose bearings are known to be tight, may be traced to the magneto, or more probably to the coupling through which the magneto is driven. Knocking at this point can generally be felt by touching the magneto bearing and the bearing of the magneto driving gear. Occasionally it may be found that the driving end of the armature shaft is loose in the bronze disc which is screwed to the armature core. Such looseness may easily be remedied by rocking the shaft when it can be removed from the engine. Nothing is more jarring to the well-trained mechanical ear than a persistent noise emanating from the motor, and it is frequently the case that it is all out of proportion to the seriousness of its cause, which may be utterly trivial, though the result is such as to make the experienced driver fear that a disaster may be imminent. A loose accessory often causes suspicion to be cast on the motor.

THE LIMITATIONS OF THE UNIVERSAL JOINT

By H. VANDERBEEK.

ALTHOUGH the universal joint, originally known as Hooke's coupling, has been widely used for feed mechanisms on machine tools, for driving drill spindles, and in agricultural machinery, it was not generally employed for the transmission of considerable powers until the advent of the bevel-gear-driven-rear-axle automobile. Fundamentally, the universal joint is a device for the transmission of rotary motion between two shafts

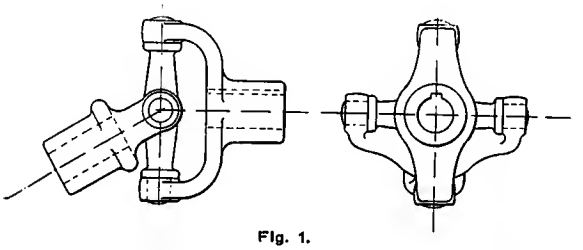

Fig. 1.

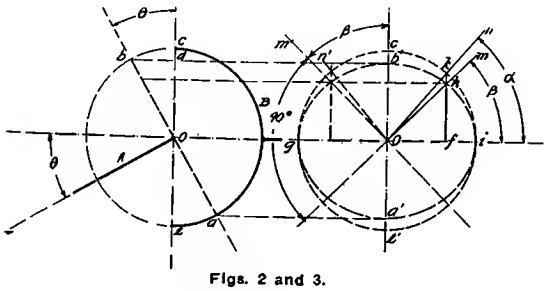
whose axes intersect in a point, with varying angles with each other; and although modified forms of the device are made which allow for lateral displacement of the axes, it is the purpose of the writer to analyze the operation, and determine the peculiarities and limitations of the universal joint in its true form; the modifications must necessarily be considered as individual cases, and are outside the scope of this article.

In its simple form, the universal joint consists of two shaft-ends terminating in forks and connected to each other by a cross member having two bearing axes at right angles to each other and which engage with corresponding journal bearings in the forks. This arrangement is shown in Fig. 1, and although joints



Figs. 2 and 3.

are made which differ in constructional details, the principles of this fundamental form apply in most cases. We will now proceed to the analysis of the movements of the several parts of the mechanism, when in operation, and for the sake of clearness, we will construct the diagrammatic view Fig 2, of the parts in the same position as in Fig. 1, and also the side projection Fig. 3.

Assuming that the joint has a position as shown in Fig. 1, where the fork B lies with its shaft axis and its cross axis both in the plane of the drawing and the fork A with its shaft axis in the plane of the drawing, and making an angle of θ with the axis of B, then the cross axis will have a position perpendicular to the plane of the drawing. It is evident that in rotation the extremities of the fork B will always move in the line c-e, Fig. 2, and in the circle c'-g-e'-i, Fig. 3, while the extremities of the fork A will describe the line b-a, Fig. 2, and the projection of this trace, in Fig. 3, will be the ellipse, i-b'-g-a'. Starting from the position, c'-e', as shown in Fig. 3, the fork B being at c' and e' and the fork A at i and g, we turn fork B through some angle β, then the trace of the point i, of the fork A will be along the ellipse and its location will be determined by the point of intersection of the ellipse and the line o-m, which is drawn at right angles to o-m', since the projection of the cross axes must always be at right angles to each other, because the axes are themselves perpendicular to each other and one of them lies in the plane of the projection, Fig. 3.

We have then determined the projection, in Fig. 3, of the cross axis of A in its new position, but since this line in its true position lies in the plane b-o-a, it is necessary, in order to determine its actual position, to swing the plane b-o-a into the plane of Fig. 3, and we then find that the point h travels to k, and that o-k is the true position of the cross axis of A in relation to its shaft axis, and that the member A has moved through an angle α, while the member B, has moved through an angle β.

It is now necessary to determine the dimensions of the angle α in terms of the angles β and Θ.

From the properties of the ellipse we know,

$$fk : fh :: oi : ob'$$

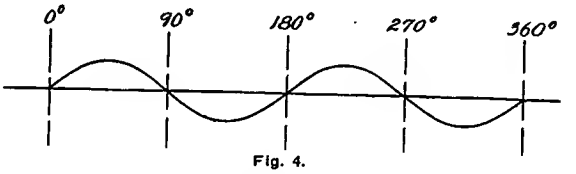


Fig. 4.

where oi is the semi-major axis and o-b' is the semi-minor axis. and from Fig. 3, we see that,

$$fk : fh :: \tan\alpha : \tan\beta$$

therefore,

$$\tan\alpha : \tan\beta :: oi : ob'$$

but,

$$oi = ob \text{ and } ob' = ob\cos\Theta$$

therefore,

$$\tan\alpha : \tan\beta :: ob : ob\cos\Theta$$

or,

$$\tan\alpha = \frac{\tan\beta}{\cos\Theta}$$

which is the algebraic expression for the angle moved through by B, in terms of the inclination of the shaft axes and the angle moved through by A. It will be noted that when $\alpha = \Theta$. $B = O$ and also that when $\alpha = 90$ degrees $\beta = 90$ degrees, or in other words, that four times in every revolution, the two forks stand

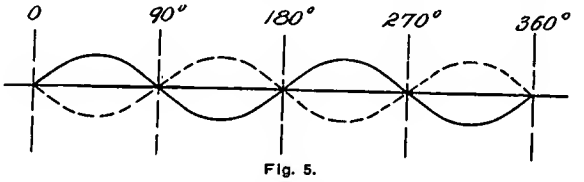

Fig. 5.

at 90 degrees with each other, and it is also evident that the maximum variation will occur midway between these positions.

Referring again to Fig. 3, and continuing the rotation of B for 90 degrees, we see that o-n of A will be at o-n' and is behind the member A an angular difference equal to the amount it was in advance in the former position, or in other words, its angular position is now negative while it was positive before. (The angular position must not here be confused with the angular velocity.) From what we have seen we may conclude that this

*Paper read at the Third Quarterly Meeting of the Society of Automobile Engineers, Cleveland, O., September 18-19, 1908.

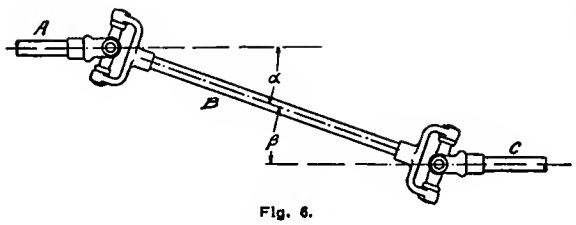

Fig. 6.

same angular relation is repeated in the two remaining quadrants of the cycle, and we may plot these relative positions; Fig. 4.

In practical application of the above, the maximum angular variation between the two members is probably of more interest than the angular velocity ratio, and in order to present this variation in concrete form, the following table will be of value.

Angle θ between shaft axes.	Maximum angular variation.	Length of arc, of circle of 3" diameter.
5°	6.57′	.00286 inches
10°	26.35′	.01149 "
15°	59.60′	.0260 "
20°	1°46.90′	.0466 "

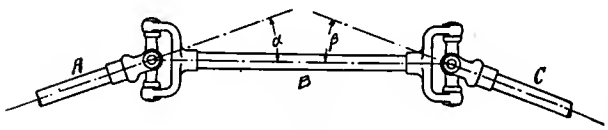

Fig. 7.

The angular variation and the length of the arc in the above are given as the numerical difference, which occurs both positively and negatively, twice in every revolution.

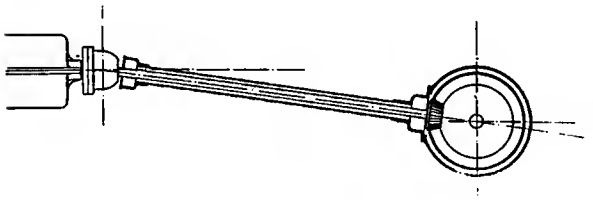

Fig. 8.

Recognizing this defect in the operation of a universal joint, it is customary, where smooth running between driver and driven parts is desired, to use them in pairs; the effect of this arrangement is to correct the variation of one joint by the complementary variation of the other. The graphical illustration of the effect of using joints in pairs, may be shown by referring to Fig. 4, and superimposing on this curve, that of another joint, in phase with the first but of opposite sign, as shown in Fig. 5.

The conditions, however, which must be met in order to give this result, are: That the fork axes of the stems of the intermediate shaft *B*, must lie in the same plane, and that the angle between both extreme shafts and the intermediate shaft shall be the same; this may be either as shown in Fig. 6, or as in Fig. 7, so long as the angle α equals the angle β. Evidently, the intermediate shaft, *B*, will have a varying angular velocity, but as this member is of small diameter and of light weight its non-uniform motion will cause no trouble in ordinary cases. It must be borne in mind, however, that we deal here only with that condition in which the axes of the driving and driven shafts, *A* and *C*, lie in some common plane; an analysis of the case where these shafts lie in different planes is more complex and is beyond the scope of this article. In the application of the universal joint to the main drive of automobiles, designers have commonly chosen one of the arrangements shown; Figs. 8, 9, and 10.

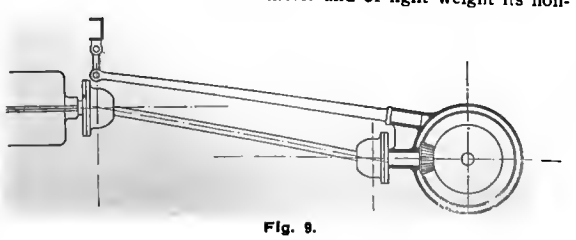

Fig. 9.

The construction as shown in Fig. 8, includes only one universal joint, and the torsion resisting member is concentric with the extension of the pinion shaft. In Fig. 9, one universal joint is used at the forward end of the propeller shaft, and the connection with the pinion shaft is by means of a semi-universal or more properly, a flexible coupling, which is universal only to a small extent and its function is to allow for discrepancies in alignment and end motion and it normally works in practically a straight line. Fig. 10 shows the use of two full universals; the torsion member being independent, as is the case in Fig. 9.

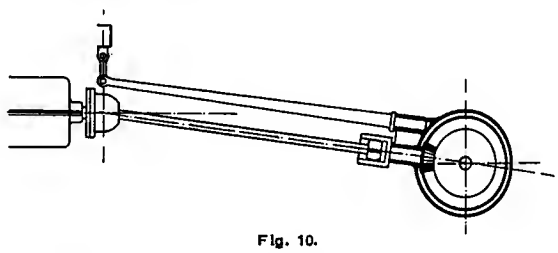

Fig. 10.

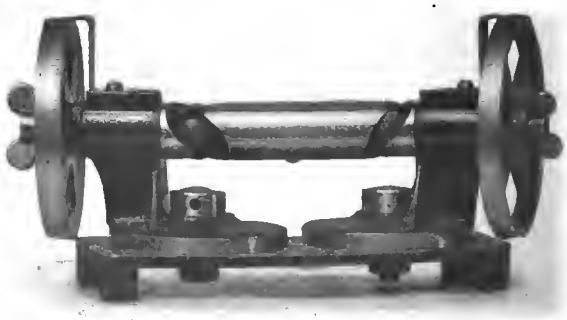
It will be noted that in the construction, Fig. 8, the driving pinion will have the varying angular velocity of a single universal joint, and the amount will depend on the angle at which the joint operates. The effect of the arrangement Fig. 9 is the same as that of the arrangement Fig. 8, but in Fig. 10, it is possible by means of the double joint to eliminate the variation.

By referring to the table given above, we may note directly the approximate variation from normal, at the pitch line of the driving pinion, for conditions such as shown in Figs. 8 and 9; the amount given being calculated on the basis of a 3-inch pinion.

The foregoing calculations are not intended to discredit any one type of construction, but rather to indicate the laws which determine the practical limitations of this particular type of mechanism. In conclusion, it may properly be said, that familiarity with the universal joint breeds respect, and although it seems to be called into service only as a last resort, the generous wearing surfaces, low rubbing speeds and smooth operation of a well designed universal must appeal as having mechanical virtues worthy of consideration. Given the same amount of time and thought in development which has been expended on the theory, design and manufacturing methods of bevel gears, it can easily be imagined that the universal joint would, in many cases, give a better performance than its accepted rivals.



Model Constructed by the Author to Prove His Theories.

PRACTICAL HINTS ON HANDLING A CAR

By ARTHUR H. DENISON.

IT would be hard to find two drivers who would handle a car alike. This is due to the experience the drivers have had, and their knowledge of the theory and principles of automobile driving and control. The owner of a new car will find that he cannot get as much out of it as the demonstrator for some little time, or till he is thoroughly accustomed to the car and knows how to handle it, whether traveling up hill or on the level.

Given suitable conditions, the gas engine will run indefinitely. A very slight fault will often cause an enormous amount of trouble, the symptoms of which may not be plain enough to enable the trouble to be located directly, and the whole system must be gone over sometimes before it is located. It is, therefore, necessary to know just what is happening under the bonnet, and just when some things should happen, that reasonable satisfaction may be derived from the car. There is no car that can be expected to be free from trouble, for even the best workmanship and material may give way sometimes.

Difficulties Met with in Starting Motor.

If a motor does not start on the first turn of the crank there is nothing radically wrong. On the first turn, or first piston passing over compression, the resistance due to compression may be felt, but the vapor compressed may not be a combustible mixture. It may be necessary to throw all four pistons over, and this will allow all four cylinders to be filled with a fresh charge of gas. The motor will then usually start on the next turn. While the modern carburetter is very sensitive, the height of the gasoline in the stand pipes, as controlled by the float, may be adjusted so low that the suction from the motor, when turned over by hand, is not sufficient to raise any gasoline, yet when running will work perfectly. There is, what may be termed, a critical adjustment to all types of carburetters and each has a corresponding throttle opening that has a great deal to do with the labor necessary to start the motor. This adjustment is not alike on any two carburetters and may range from a throttle opening of two or three notches to half or three-quarters on the control quadrant. If the throttle is open *too* much, and the motor being turned over by hand, the inlet valve is open for an appreciable length of time, and the piston is traveling at a very slow rate of speed in comparison to that when running. Under these conditions the rate of speed of the air currents flowing through the carburetter is so low that gasoline is not drawn from the spray nozzle, and though a certain amount of vapor is lifted by the column of air passing over the gasoline, the quantity is not sufficient to make a mixture that will ignite. On the other hand, if the throttle is not open enough the motor will choke itself, drawing too much gasoline. The suction is strong enough to draw the gasoline, probably in the form of fine drops, into the cylinder, where it is vaporized under the heat of compression and will either provide a mixture too rich to ignite or one that will burn so slowly that sufficient power is not developed to carry the motor over the following compression. Many motors will not run satisfactory till thoroughly warmed up and the warm-air inlet or hot-water jacket to the carburetter cannot furnish their necessary quota of heat until the motor has been running for some little time.

Handling of the Spark—Jump Spark Ignition.

The position of the spark lever when starting is important. If the car is provided with jump spark ignition, the system is usually arranged to permit starting on the spark. To allow this the full retard must be arranged so that the cylinder, whose piston is on its firing stroke, will allow ignition to take place with the piston half way down. Here the tension of the gas in the cylinder is very much less than that when on the dead center. If the motor has been standing and is cool, the tension of the gas falls to atmospheric pressure on account of the leakage and giving up of its heat. For this reason the term "starting on compression" is not correct. The motor will not retain a charge of gas at a pressure above that of the atmosphere for any length of time because of leakage through the piston rings, etc. To prove that it is not compression but merely the expansive action of the gas ignited at atmospheric pressure, which causes motor to start, the spark plugs may be taken out and replaced, and if the mixture remaining in the cylinder has the proper proportions of air and gasoline the motor will start when the spark is switched on. When the plug is out there would be an open passage from the compression space to the atmosphere, and according to the laws of air and gas, any pressure in the cylinder above that of the surrounding atmosphere would be immediately dissipated. This may be proved also by merely opening the petcock of the cylinder on compression. If the spark lever is fully retarded and the current switched on, igniting the gas, the resistance due to inertia must be overcome. The piston, already half way through its stroke, will only travel an inch or so further before the exhaust valve will open and the remaining energy developed by the charge will be directed out through the open port. Unless enough energy is stored in the flywheel to carry the motor over the following compression the motor will stop. This may happen whether an attempt is made to start on the spark or by turning it over with the starting crank. In either case one explosion may be heard and then the motor stops. This trouble is rather mysterious, but can be readily overcome by advancing the spark lever the distance of an inch to an inch and a half along the circumference of its quadrant, thus securing the initial impulse taking place just after the piston has commenced the power stroke. One quick jerk, throwing the piston over compression will do more good than five minutes' slow cranking. The manufacturer should set the starting crank so that the maximum compression should be felt when the crank is about 10 degrees past the horizontal. If the motor starts readily on the spark, and it will if the carbureter adjustment is such that the mixture is a trifle rich, the usual practice is to throw the control lever to full retard to secure the initial impulse and then advance it to normal running position.

Handling of the Spark—Make and Break.

A motor equipped with make-and-break ignition usually has the igniters set fully retarded, i. e., to fire a fraction of an inch past dead center. On a motor of this type a back-fire is very liable to occur if the spark lever is advanced only a few notches. In order to escape the serious consequences that may follow this (many arms and wrists have been broken) a good habit to cultivate is that of returning the spark advance and throttle levers to the proper position for cranking the motor before leaving the car, or immediately on stopping the motor. When on the road the best results are usually obtained by advancing the spark lever as far as possible without the motors pounding. With the make-and-brake system it is customary to advance the igniters to a fixed point and control the speed of the car with the throttle. Rules for handling the spark lever cannot be laid down, as conditions vary with the kinds of roads being traveled, difference in motors, etc., but a good driver will not allow the motors to pound.

One Frequent Cause of Inlet Valves Leaking.

A good feature on an American car is an adjustment that will allow the operator to throttle his motor to as low a speed as desired when the load is off. The connection is placed on the dash. The general practice among drivers, when wishing to keep the motors running slowly, is to retard both spark and throttle levers as much as possible, the adjustments being usually set to allow the motors to just keep running under these conditions. This practice is responsible for the need of grinding in valves at short intervals. With the spark lever retarded, the gas is ignited so late in the stroke that the exhaust valve opens before the

charge is burnt, consequently the gas at a very high temperature is passing between the valve and its seat, heating both to an unnecessary extent. The cool gas, coming in on the suction stroke, will help the water-cooling system to keep the valve cool, but even with this help it will not withstand the heat very long and is soon warped, allowing leakage during the compression stroke. The remedy is to adjust the throttle so that the motor may be run as slow as desired with the spark advanced so that ignition is taking place nearer dead center.

Proper Care and Operation of Clutch.

Successful operation of the clutch cannot be expected unless the clutch, the pedal connections and universal joints between the clutcb and gear box are cared for. Clutches employing leather as one of the friction surfaces, such as the cone and expanding types, need pretty regular attention. To insure the best results the leather should be kept soft and pliable as a razor strop. The multiple-disc clutch usually runs in oil and gives little trouble. As the oil has to be squeezed out before the clutch can take hold, this type of clutch is easier on the car and less liable to be injured by careless handling. It is by no means rare to see the rear wheels of a car jump off the ground when a "fierce" clutch takes hold. This racks the car a great deal, and is very destructive on tires. Castor oil or neatsfoot oil make an excellent dressing for clutch leathers.

Handling of Gears Sure Test of Driver's Ability.

Skillful handling of the gear-shifting lever on a sliding-gear system can only be obtained by practice. One of the best tests of a driver's skill is to notice the way be handles his gears. A skillful man, accustomed to a car, will pass through all speeds, either up or down, noiselessly, unless for the click caused by the lever bringing up against the quadrant. There are two systems in general use, and they are termed the Progressive and Selective. In the progressive, the different gears are meshed by a lever working in a single path, either forward or backward. In general practice it is arranged with three speeds forward and reverse, occasionally four speeds forward. It was brought out by the Panhard Company, who still use it.

The Selective system originated with the Mercedes Company and has many advantages over the Progressive. The name—Selective—indicates that the neutral position of tbe lever is so arranged that any gear combination may be engaged, and the lever may pass from any gear directly to neutral without passing through any other gear, something impossible with the Progressive system.

With the Progressive gear the system is usually arranged so that reverse is in mesh witb the lever at the extreme rear and high speed at the forward end of the quadrant, the intermediate speeds proportioned in between. The lever usually has a button on top, controlling a latch that locks it in place at any desired speed by fitting into a slot cut in the quadrant. The easiest method of securing the proper amount of travel, from one speed to another, is the following: Press the button or finger clasp that releases the latch from its slot, and while holding it released move the lever far enough to prevent its slipping back into the slot when the button is released. The latch will now be pressing against the quadrant bar, and the lever can be moved until the desired gear is properly meshed, where the influence of the spring will pull the latch into the slot and lock the lever. If the latch is held released the result may be that the lever be carried too far into the following neutral. If this occurs the best thing to do is to stop and come back to first speed again.

The Progressive gear, as worked out by the Packard Company, does not have a locking device on the lever, the same result being obtained by a device in the gear box. When shifting from first to second, or from third back to second, the lever should be carried rapidly forward or backward until the gears are felt to engage. The locking device, though not automatic, will check the travel of the lever, and if the gears are properly in mesh will provide sufficient resistance to the movement of the lever to assure the operator that the gears are correctly in mesh.

Drivers handling the Selective system have two things to remember. The first is to keep it well oiled that the lever may slide freely sideways. The second is to keep their hands off the button unless it is desired to enter reverse. The lever works in an H slot, the cross bar of which represents the neutral path. Reverse is reached by providing a third path outside, and to prevent the lever entering it accidentally a projection is cast on the plate. Tbe lever is provided with a latch, controlled by the usual buttou on top, and when the button is pressed the latch is thrown to clear this projection. The lever will then pass freely to engage with the reverse sbifting rod. To mesh the gear it is moved backward or forward in the usual way.

Some cars have appeared on the market with the speeds arranged like this R 2 4. If on a bill and conditions demand a
1 3
change to a lower gear, say, third back to second, if the driver handles the lever without touching the button, he will have no trouble. If he does, he is almost sure to enter reverse, with possibly serious consequences.

The clutch should be thrown as far forward as possible before any attempt is made to engage the gears. (Some cars have appeared with only one pedal so arranged that the clutch was first released and furtber travel of the pedal applied the running brakes.) The different types of clutches in use and the care bestowed on them has much to do with the ease with which the gears may be engaged. The cone clutch, with its comparatively large diameter, is likely to spin longer than the multiple disc. Any attempt to mesh the gears while the clutch is spinning will result in the gears growling, possibly chipping the teeth. Few types of clutch can be depended on to stop spinning as soon as the clutch pedal is pressed, and it is advisable to wait a moment or two before attempting to engage the gears. Occasionally the shaft will stop so that the teeth of one gear will strike the teeth of the other and prevent them meshing. When this occurs engage the clutch again for an instant, thus letting the clutch shaft spin, and after giving them time to stop spinning try to mesh the gears again. After the car has started and it is desired to shift from first to second, etc., speed the engine for a moment, close the throttle, then release the clutch and shift tbe gears. If the engine has not reached too high a speed this will allow the gears to engage quietly.

Never attempt to force the gears into mesh. If they will not engage without being forced, there is something wrong and jamming down hard on the lever is only liable to aggravate the trouble or spring the shifting arm or lever. The noise or growl so frequently heard is caused by the attempt to force the gears together while they are traveling at different rates of speed. This serves to grind and chip the edges, occasionally breaking the teeth. Judging from the condition of the gears from the majority of cars in the repair shop, the only conclusion is that the average driver seldom waits long enough before attempting to engage first speed. In some instances careless handling has resulted in allowing the clutch to take hold when only half the teeth were in mesh and the teeth were half ground away.

Handling a Car on the Road.

Very little can be said about handling the car on the road. The operator must handle each separate case as he meets it. New York has policemen whose sole duty is to regulate traffic. On a country road the farmer will either give the motorist the whole road or won't move until he has to. He isn't a bit particular whether he turns to the right or left. Similarly when following and trying to overtake another automobile on the road, the driver of the leading machine may try to prevent the other car from passing him, or may take that side of the road that looks best to him regardless of rules or laws. Wben passing little breaks in the road caused by water running off and carrying the road material with it, holes in pavement, etc., the shock of striking the edges is rather severe on tires and may be lessened by releasing the clutch for the moment and allowing the car to coast, always taking "waterbreaks" and similar rough spots straight on, so as not to strain the car unnecessarily.

LETTERS INTERESTING AND INSTRUCTIVE

HIGH AND LOW TENSION MAGNETOS.

Editor THE AUTOMOBILE:

[1,574.]—Will you kindly explain through "Letters Intereeting and Instructive" the difference between high and low tenelon magnetos? I mean the difference in working parts and the eystems with which they are used. I think a great many people would be interested in an explanation of this, because, for some reaeon or other, literature on this subject seems very scarce and uninforming. I have been told that low tension magnetos can only be used with make-and-break ignition. Is this correct?

Ludington, Mich. M. E. CARTIER.

There is considerable vagueness and inaccuracy, at least from a strictly electrical standpoint, in the description of automobile magnetos, and this is no doubt responsible for much of the popular confusion. The simplest form of magneto is the low-tension, which consists of a number of permanent horseshoe magnets and an armature rotating between their poles.. As the armature cuts the "lines of force" of the magnets an electrical current is set up in its coils, and this is collected by a suitable brush. In this form the magneto is generally used with make-and-break ignition, but it could be used with jump-spark also, in connection with a timer and spark-coils, or a timer, single coil and high-tension distributor. As a rule, however, when this type is used with jump-spark, the timer and distributor are mounted on the magneto, and it is then usually called a "high-tension" magneto. As mentioned above, this name is electrically incorrect, for the magneto generates only a low-tension current, which is then transformed by a separate spark-coil. About half of the so-called "high-tension" magnetos on the market are of this type.

A true high-tension magneto, on the other hand, has a second winding on its armature which takes the place of the spark-coil, so that its current when collected for distribution is already high-tension. There is little difference in the external appearance of the two types, and the only sure way for the layman to distinguish between them is to look for the separate spark-coil.

QUESTIONS ON IGNITION SYSTEMS.

Editor THE AUTOMOBILE:

[1,575.]—In your "Lettere Interesting and Instructive" will you please give me the following information:

1. What is the best voltage for ignition with the make and break system (low voltage interchangeable with dry cells)?
2. Can a make and break system be ueed without an induction coil?
3. Is it practicable to use an Apple dynamo on a make and break system without the coil, and if not, why?
4. What is the advantage of using water with the gasoline mixture?
5. Can water be utilized to the same advantage with alcohol?
6. In testing dry cells to get at the comparative life of different makes of batteries, how long should they operate constantly on a coil requiring one ampere (not on a machine)?

Manila, P. I. F. H. THOMPSON.

1. The low-tension magnetos used for this purpose usually generate about 100 volts at their maximum speed; with dry cells an induction coil must be used.

2. With a magneto, yes; but with dry cells the coil is necessary. The coil used need not be as powerful as the regular jump spark coil. Most manufacturers of electrical goods have a special type for make-and-break ignition.

3. No, because the Apple dynamo has only about the same voltage as a set of dry cells.

4. There is no advantage we know of; in fact, a little water in the gasoline will usually stop the motor entirely.

5. A small amount of water in alcohol makes no difference.

6. The cells should last as many hours on a one-ampere coil as the number of ampere-hours of their rating, which depends on their size. It is not fair to the batteries, however, to run them constantly, as they give much better results when used only intermittently, as for ignition on a gasoline engine.

LARGE WHEELS AND LONG WHEELBASE.

Editor THE AUTOMOBILE:

[1,576.]—I have a suggestion to make with reference to tires for the "ideal car." I have owned two machines already and know how tired one gets of punctured tires. We must use pneumatic tires on wheels between 30 and 40 inches in diameter on American roads. But would not eolid tires on 50-inch wheels give as smooth running as pneumatic tires on 36-inch wheele? I belleve they would. A larger wheelbase would alao help the riding qualitiee. Wheels and frames would both have to be stronger and frames would have to be dropped in order to retain the same center of gravity for the entire car. But I believe that the advantages of 50-inch eolid tiree and 160 inches wheelbase for seven-passenger cars and 44-inch solid tiree and 136 inches wheelbase for runabouts (high-power cars only being considered) would far exceed the disadvantages.

La Fayette, Ind. A. L. SHERIDAN.

There can be no doubt that the sizes of tires and wheelbase which you suggest would give sufficiently easy riding, but the key to the situation is in the last sentence. Would the advantages exceed the disadvantages? Most manufacturers seem to think that they would not. The weight of the car would be enormously increased, and the steering would be very awkward, requiring a 10-acre lot to turn around in. The larger the wheels, the smaller is the maximum angle through which they can be turned for steering, without striking the frame; and the longer the wheelbase, the greater is the steering angle required for turning in a given radius. Thus you are increasing your difficulties in two ways at once.

AN IDEAL CAR OF IMPOSING DIMENSIONS.

Editor THE AUTOMOBILE:

[1,577.]—Under your very expreselvely and accurately named heading, "Lettere Interesting and Instructive," will you kindly furnieh the following information?

1. For a man who does not want to go shopping, marketing or on exhibition through city streets, but who wants to get out in the country close to Nature and divide this luxurious experience with hie family and a few friende, and yet who has to go over roads (not pikes), is not a 60-horsepower, 7-passenger, 168-inch wheelbase, 60-inch tread the ideai car?
2. With the above wheelbase and tread would not a car having 44-inch wheele be as free from skidding as present sizes?
3. Are not the majority of bodiee for seven passengers too short for comfortable riding for more than an hour or two?
4. If spark is advanced until the mixture ie fired before the crankshaft has passed dead center does it have any appreciable effect on heating the cylinders? LEARNER.

Birmingham, Ala.

1. Your "ideal" is entirely too large for any practical use; on the roads you speak of you would find it about as manageable as a small locomotive. Half the power and two-thirds the wheelbase would serve you much better.

2. The only way to find out would be to build such a car and make experiments.

3. Not necessarily; they are usually very well designed.

4. No, advancing the spark prevents heating, owing to the rapid firing and exhaust of the charge, while retarding the spark causes the motor to heat, but there is a limit to the advance.

OVERCOMING THE CARBURETER "POPPING."

Editor THE AUTOMOBILE:

[1,578.]—I own a Mitchell (1908) touring car on which is a Holley carbureter. This carbureter has worked perfectly until a month or so ago, when on cranking the engine it would "pop" several timee before settling down to work. It has been getting worse and worse until now it is all I can do to start the engine. It will "pop" maybe for fifteen minutes before I can go; after that it goee as well as it ever did. After the motor has stopped sometimes only fifteen or twenty minutes, it is very hard to start it again, no matter how hot the cylinders are or how warm the day. I have taken the carbureter all apart, but can find no dirt or anything in it, or no parts worn or broken. I know it is adjusted right, although now I cannot start on the epark immediatsly after stopping the engine. The valves are in good condition, too. I know the gasoline to be all right, and the pipes leading to the carbureter to be clear.

If you could suggest anything to overcome the trouble, I would be very greatly obliged. W. N. HUTCHINGS.

Mooelc, Pa.

You do not state whether the Holley carbureter you have on your machine is of the new Venturi tube type, more familiarly known as the "puddle" type, or of the spray nozzle variety, although, as a matter of fact, "popping" usually proceeds from a similar cause regardless of the type of carbureter. It is set up by the fact that the mixture is either too rich or too weak and on that account continues to burn, not only throughout the length of the stroke, but after the exhaust valve has closed. This maintains considerable excess pressure in the cylinder, which naturally escapes through the inlet valve the moment the latter opens; it is the release of this pressure through the inlet valve that constitutes what is familiarly known as "carbureter popping," and it can usually be remedied by making the proper air and fuel adjustments at the carbureter.

The fact that in your case it occurred at first only at starting was an indication that the carbureter adjustment was more nearly correct for the engine requirements at the higher speeds, and as soon as the motor speeded up a bit, it ceased. We very much fear that your "I know it is adjusted right" may not be entirely based upon fact, and if you will overcome this fault you will probably find that there is nothing else the matter. If you will carefully read H. L. Towle's "Getting Acquainted with a Carbureter," which appeared in THE AUTOMOBILE of September 24, we think you will find a great many more pointers than could well be put in a reply to your letter in these columns.

ADVANTAGES OF A FIXED POINT OF IGNITION.

Editor THE AUTOMOBILE:

[1,579.]—Will you kindly describe in "Letters Interesting and Instructive" the advantagee and disadvantages of a fixed poInt of firing for machines depending upon a magneto for ignition.

Alameda, Cal. HENRY M. POND, M.D.

To begin at the tail end, we do not know of any particular disadvantages arising from the use of a fixed point of firing the charge where both the magneto and the rest of the system have been properly designed. Of 30 representative French motors, probably 40 per cent. were found to be equipped in this manner. On the other hand, its advantages are that the motor is always run with a uniform firing point, which should not only tend to increase its average efficiency, but also to lengthen its life. As the magneto is not subject to the various factors of "lag" that are present in the coil and battery system, there is not the same necessity for providing a wide range of advance. It is customary to provide means for retarding the magneto for starting, but as the latter does not generate as efficiently at the lower speed of cranking, as it does with the motor running, this is but slight. The magneto's voltage increases with its speed and, in consequence, it automatically takes care of the slight amount of extra advance required over that at which it is set. Practice is tending slowly in this direction and doubtless the fixed point of ignition will, sooner or later, become general.

SEASON FOR NON-FREEZING SOLUTIONS OPENS.

Editor THE AUTOMOBILE:

[1,580.]—Will you kindly advise me how low a degree of temperature a solution of one-half alcohol and one-half water, put in my radiator, will stand before freezing. Will you also advise ms if wood alcohol will serve as well as grain alcohol in this case. Is there anything better that I could use for this purpose?

Ansonia, Conn. LUCIUS B. TERRELL.

A 25 per cent. solution of alcohol and water will resist freezing down to zero Fehrenheit, so that a 50 per cent. solution such as you mention would doubtless be capable of resisting any temperatures prevailing here in the East. Wood alcohol will serve as well as grain alcohol, but neither carries with it a very strong recommendation for the purpose, owing to the instability of the solution, i. e., its constant loss by evaporation, and as the alcohol boils at a much lower temperature than the water, the former will pass off much more rapidly, constantly decreasing the ability of the solution as a whole to withstand freezing. The wood alcohol also attacks the rubber hose connections. A better non-freezing solution may be obtained by using calcium chloride; a 25 per cent. solution will withstand a zero temperature, and below that will only become mushy and not freeze solid enough to do any damage, unless the cold were of a severity seldom known in this part of the country. Increasing the proportions will naturally increase its non-freezing properties.

ON THE SPARE-WHEEL BALL-BEARING QUESTION.

Editor THE AUTOMOBILE:

[1,581.]—In relation to the criticism by Henry Hess, publisbed in "The Automobile" of September 17, page 401, involving the use of a spare wheel (in an emergency) ae advocated and sold by the Spare Motor Wheel Company of America, Ltd. (Stspney Spare Wheel), I desire to say, the placing of the extra wheel outside of the regular wheel and fastened thereto, but utilizing the regular wheel hub (and, ae a consequence, the ball-bearings in the regular hub), must, as Mr. Hess states, transfer the plans of the load. Thus is one bearing relieved of some of ite burden, and if it is weak, it must accordingly congratulate itself, as it were. But if Peter is thus deprived of hie burden, Paul muet tote it for a while. If Peter ie so weak as to rejoice at the loss of the burden, Paul must also be a little off of the top as well, since Peter and Paul ars botb in the eame boat. (Two bearings in one wheel hub.)

There was a time in the history of ball bearings when their life was short, even with no great load. Time wrought changes, and in time a factor of safety crept into the zone, now dominated by ball bearings. This factor of safety is cialmed to be very large when purchases of ball bearinge are made, and experience has proven that the goods are generally delivered on a basis far more reliable than can be claimed for the dslivery of coal.

Builders of care have great respect for the advice of ths maker of ball bearings, which respect is shown in a most satiefactory way, in that the bearings are (I might say) invariably larger than the makere of ball bearings are wont to recommend.

Under the circumstances, then, it does seem ae if the Stepney spare wheel, or any other devlce of the kind, will scarcely disturb the obvious serenity of the ball bearings in the wheel hub.

No man would be justified in riding in an automobile if hs was skating on the thin Ice portrayed in the condition that is represented by the possible failure of the ball bearings in the wheel bubs, merely because the plane of the load has been traneferred a distance equal to the section diameter of a tire.

As Mr. Hess says, limit the time of the use of the epare wbeel to the time during which it serves its obvious purpose, but who would want to keep ths epare wheel on any longer? On ths other hand, the spare wheel will not level the road inequalities, and these inequalities certainly strese ball bearings more than any spare wheel possibly can.

It le perfectly reasonable to aesume that an autoist wbo has to apply the spars wheel will be a little more careful over considerable road inequalitiee than he would ordinarily be, and this difference will surely amount to more than that resultant of ths small transfer of the plan of the plane of the load, due to the use of s spare wheel.

Automobiliets who are not sharps, when it comes to mschanical hair splitting, might think that ball bearings are weaklings, so easily disruptsd that the mere application of a spare wbsel would do the trick. Were they to reach euch a point in a scheme of reasoning, more inertia would impel them further, and they would (according to the law of probabilities) reach the final conclusion that a mile a minute in a car fitted with wheele that would surely come off if the ball bearinge were to go to piecss is too near heaven. THOMAS J. FAY.

Brooklyn, N. Y.

ABOUT DELAGE'S "MONO" IN THE GRAND PRIX.

Editor THE AUTOMOBILE:

[1,582.]—I notice in Mr. Ricker's letter in your last issue—September 24—a slight error regarding the Delage Voiturettş, winner of the Dieppe race of last July, which I should like to correct. All of the Delage cars were single cylinder 100 m.m. bore by 160 m.m. stroke. Guyot's motor was designed by Delage and built at the Ds Dion works, and the other motors were De Dions specially built for the race. Guyot's motor was one of the most beautifully balanced ones that I have ever seen. Of couree I am referring to "one lungers" only, or "mono'e," as we call them over there. When the motor was cranked, the chassis would vibrate vertically; there was no side rocking as in the other cars. Aside from ths motors, the care were mads up entirely of stock parts. Delage is a friend of mine, and I was with him at Londinieres.

New York City. SANFORD POMEROY.

HOW TO ATTACK THE ROADS' DUST PROBLEM

WASHINGTON, D. C., Oct. 5.—Excerpts from a report on dust preventives prepared for the Department of Agriculture by Prevost Hubbard, assistant chemist in the Office of Public Roads, and just issued for general distribution, are of more than passing interest to automobilists. The report says:

"The suppression of dust on roads is a problem which has become prominent only within recent years, but its importance is rapidly increasing, as it involves the saving of much money and the comfort and convenience of the public at large, as well as of road users. In arriving at a complete understanding of a subject of this kind it is essential that as broad a view of it as possible be obtained, and, in order to achieve this result, one must look at the matter from at least three different standpoints—that of the engineer, the chemist, and the layman. The direct solution of the problem depends to a great extent, of course, upon the efforts of the road engineer, but the aid of the chemist and road user will eventually prove to be important factors which cannot be overlooked. The subject is one which also deserves the attention of the general public, as it has a very direct bearing upon matters which are of universal interest.

A Moon Among the Colorado Mountains.
Fred C. Merry and family of Kansas City, Mo., who toured from Kansas City to Denver in their Moon automobile. The picture is interesting as showing the kind of country tourists can traverse nowadays.

"In considering the cause, or rather the causes, of dust formation a few general remarks may not be out of place. The term 'wear,' when applied to solid substances, undoubtedly expresses the fundamental cause of such formation, although other factors which make wear possible and which tend to remove and distribute the dust formed play important parts. All forces which tend to disintegrate or destroy will of necessity produce wear, and these forces, when considered in connection with roads, may be conveniently classed under three heads—chemical, physical and mechanical.

"The automobile is, perhaps, the most potent factor which at the present time operates to produce dust and destroy roads. When moving at a high rate of speed its broad rubber tires exert a pulling or lifting effect upon all loose material on the road surface and a cloud of dust is sucked up and carried along behind each vehicle. The slightest current of air then carries the dust cloud over the surrounding country. The enormous increase in the last few years of fast motor traffic along public highways has aroused general interest in the subject of dust prevention.

"The coincidence of the appearance of the automobile with the aroused interest in the dust nuisance has led to the impression that the former is the sole cause of the trouble. It will be remembered, however, that the dust nuisance on a somewhat smaller scale existed long before the coming of the motor car. If the automobile has resulted in an awakened interest in this problem, it will have served a valuable purpose, but besides this it has undoubtedly exerted a beneficial influence in arousing the public at large to the knowledge that good roads are necessary to the country's welfare.

"The dust problem as it stands to-day seems to be open to two methods of attack: (1) by applying materials to the road which will hold down the dust formed, or (2) by methods of construction designed to reduce the formation of dust, and therefore the wear of the road, to a minimum. Dust prevention has so far been mainly confined to the treatment of old macadam.

24 COUNTRIES SEND DELEGATES TO ROAD CONGRESS

PARIS, Oct. 4.—Twenty-four countries, including the United States, Brazil, Mexico, Chile, India and Japan, will be officially represented at the first International Road Congress, which opens its official sessions at the Tuilleries October 12. The scope of the work of the congress is very bread and great good is expected from the exchange of opinions which will take place. A glance at the numerous papers which will be read before the congress and which will have already been translated so that their contents may be available for all, emphasizes how far America is behind in the matter of roads, compared with Europe.

This is not, of course, to be wondered at considering that every country in Europe, even the most backward, has for centuries possessed the foundations of magnificent roads built for military purposes. Nevertheless, it is starting to read, for instance, that of the 2,151,570 miles of public road in the United States only 7.14 per cent., or 153,662 miles, are improved. The mileage of improved roads in the United States, therefore, is only equal to the mileage of the magnificent French National and departmental roads, which average between 24 and 25 feet in width.

A large proportion of the work of the congress is to be devoted to the consideration of the effect upon roads of new means of transport, especially automobiles, and an attempt will be made to approximate the best method of constructing the ideal road of the future. The papers of the experts agree that the essential feature of a good road is a hard core, preferably of armored concrete making an unyielding incompressible foundation with the material perfectly bound together, and the surface properly metaled and tarred to prevent dust or mud. Methods and materials suggested vary greatly, but all agree that tar up to the present time has proved most efficacious against water and the prevention of dust.

The general American delegates are L. W. Page, director of the Public Roads Bureau of the Agricultural Department; Clifford Richardson, of New York, and Col. Charles S. Bromwell, superintendent of Public Buildings and Grounds of the District of Columbia. In addition, Massachusetts sends Harold Parker,

chairman of the Highway Commission, and A. B. Fletcher; Mississippi has named Charles Scott. Bishop Galloway and Representative John Sharp Williams; Washington, Samuel Hill, and New Mexico, Numa Reymond.

NOTABLE EXPERIMENTS IN ROADMAKING.

The problem of building durable and at the same time dustless roads has become such a momentous one that men all over the country are bending their efforts towards a speedy and successful solution. The State roads, as at present constructed, have not only proved to be unsuited to the constantly increasing travel, but they are an enormous expense. With this question of expense in view, the men who are spending the most time on the problem, are working not only to find a combination of materials which will withstand any reasonable demands being made of it, but they are after a combination which will cost less.

For the last few years the scientists in the office of the public roads of the United States Department of Agriculture have been working along these lines. So far they have spent most of their time in the attempt to make use of the enormous quantity of slag which is to be found near all blast furnaces. The slag is being used to take the place of the broken stone, and combinations have been made up with both tar and asphalt. One stretch of experimental road is being constructed out of the slag asphalt combination near Chicago, under the supervision of Chief Engineer Pierce, of the Federal Bureau. Another stretch made out of the slag-tar combination is under way at Birmingham, Ala., under the direction of Assistant Engineer Heidel. These stretches will be watched with interest during the next year to see how this new class of road is going to stand the wear.

A more novel experiment is being tried near Newton, Mass., with an entirely different substance—molasses—which is almost a useless by-product of the great sugar refineries in the South and West. A half-mile stretch is being prepared where the molasses is going to be tried as a binder.

MAINE'S ADVANCE IN ROAD BUILDING.

PORTLAND, ME., Oct. 5.—On every hand there is evidence that a great advance has been made this year in plans for the construction of State roads. The many meetings held througbout Maine by State Highway Commissioner Paul D. Sargent bave borne fruit, with the result that many towns have already commenced the construction of better roads, taking advantage of the opportunity to secure money from the State, or are about to begin work.

One of the longest pieces of State road being constructed in Maine this season is in the town of Rumford Falls, where about 21-4 miles of road is nearly finished. The road in question is being constructed of macadam, with a width of 15 feet, and a special feature in connection with the work is the construction of about 3,000 feet of side sub-drain, as the road lies mostly on the side of a hill from which a large amount of subsoil water has in the past found its way into the road. The work also includes the construction of 22 culverts.

Announcement is made by Commissioner Sargent that there are 16 cities and towns in the State in which State road work has been advertised and work begun or nearly begun. These places are: Brunswick, South Berwick, Houlton, Ellsworth, Caribou, Eden, Gardiner, Madison, Fort Fairfield, Westbrook, Presque Isle, York, Rumford, Kennebunk, Sanford and Portland.

In discussing the work with a representative of THE AUTOMOBILE, Commissioner Sargent said:

"It is the aim of this department to have one good highway across the State. With that end in view, the sections of the road constructed each year are so laid out that they will join previous sections. In this way, as each town constructs a section of road, the aim of having a good highway for automobiles and all vehicles right across the State from Kittery to Calais is being gradually realized and it will be but a few years before this is completed."

SOME DANGER POINTS IN AUTOMOBILE USE

BY A. D. HARD, M. D.

SOMETIMES a very small matter leads to results of great importance. A steering gear that is not sensitive to the touch, or one that from lack of lubrication has become sticky and does not so easily respond to the force usually applied by the accustomed driver, will so hamper the control of the car that, when skidding occurs in sand or wet, the car may go over an embankment or into a ditch. The writer has investigated this matter and found that three fatal accidents which he had the opportunity to carefully examine, were due alone to this cause. When a steering gear is composed of a worm gear sliding a large nut up and down to convey motion to the steering arm, there is great danger of the nut becoming dry and working with much greater resistance to the hand on the wheel than it sbould. It is an objectionable form of steering mechanism for this reason.

Another source of danger in the steering mechanism is the slack which is so common in some cars, even when recently out of the factory. Some engineers claim that this is a good feature instead of a bad one, but I think that any experienced driver will agree with me in saying that there should be but very little slack in the motion of the steering wheel. An instantaneous response to the guiding touch is the feature we want, to guard against undue deviations when the car is going at high speed. The actual time required to deviate enough to run off a grade, or into a ditch, or into an obstruction near the roadway, is so very small that none should be wasted in turning the steering wheel to take up slack. In my opinion as an experienced driver, the steering gear mechanism of the modern car has not had as much careful attention as it deserves.

As we all know, skidding is a source of much danger to both car and occupants, as well as to other vehicles that the car may be passing. The cause of skidding is found in the action of the differential. When one wheel slips the other drive wheel loses its guiding and propelling force, and the car is deviated from side to side by the uneven traction of the wheels. Racing car drivers have found that with no differential they are much surer of their footing in bursts of speed. If we could have a differential mechanism, which only acted when the front wheel were deviated a certain distance from straightaway, and the driving axle acted as a unit under other conditions, we should have all the advantages of a differential when it was needed, and the advantages of its absence when it was not needed. Another suggestion is to have a means of locking the differential at will. Another suggestion is to employ adjustable friction disc clutches between each drive wheel and the driving axle, with an automatic release for the inside wheel when turning corners.

Guarding Against Crossing Accidents.

The large number of fatal accidents due to crossing railway tracks at the wrong time has suggested all kinds of remedies. The warning noises of an approaching train are so similar to the usual noise of the automobile that they cannot be depended upon for the safety which the horse-drawn vehicle may have, and the speed of approach is so much greater that the car driver is furtber handicapped. There is one way which seems both safe and simple. The car should be driven up to within a few feet of the track and stopped, then prospects of danger can be hardly overlooked, and the car can proceed across the track or wait for the train to pass before doing so. In some parts of the country the signs at railroad crossings read: "STOP—LOOK—LISTEN." No better warning can be devised for automobilists in crossing railroad tracks. The Irishman was right when he said: "Niver cross before a train, before the train has passed."

NEW W. & S. MAGNETO OF THE INDUCTOR TYPE

IN addition to their line of carbureters, Wheeler & Schebler, Indianapolis, will market for next year an inductor type of low-tension alternating-current magneto which takes the place of a storage cell in the ignition system of a car. The magneto is friction driven from the flywheel or belt driven from any

Fig. 1.—W. & S. Inductor Magneto.

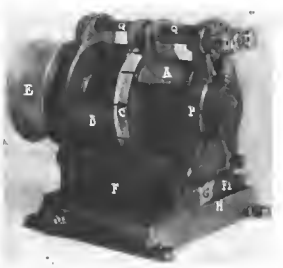


Fig. 2.—Minus the Field Magnets.

other part of the car and is made to rotate three or four times as fast as the motor crankshaft, giving a current of 5 amperes at 12 volts. For car work this inductor magneto can be used in connection with a set of dry cells, the same four-unit coil and timer being used for each and one set of plugs sufficing. Producing as it does an alternating current, it cannot be used for charging storage cells, but simply takes their place on a car.

Fig. 1 is the magneto complete with three permanent horseshoe magnets, although a double set of three is employed in all of the latest ones manufactured. At the end appears the aluminum belt pulley. In Fig. 2 the magnets and a brass case between them are removed, exposing every part of the apparatus, consisting of a rotating shaft carrying a three-pointed inductor *A* and another *B* with a coarsely wound coil *C* of flat copper ribbon between them. The ends of the copper ribbon connect directly with the binding posts *D* and *D1*, which completes the magneto. The winding *C* is stationary and nothing revolves but the two inductors *A* and *B*, which are pinned to the shaft which carries the friction wheel *E*, and which shaft revolves on a pair of F. &

Fig. 3.—The Strip Copper Winding and the Inductors.

S. ball bearings, one appearing in Fig. 5 at *M1*, carried in the end piece *P* of the magneto. In Fig. 4 appears an end view of the magneto, showing in detail one of the star-shaped inductors with its three arms 1, 2 and 3, regularly spaced at 120 degrees, and each arm consisting of twenty-seven laminations of high-frequency transformer iron pressed together and secured by soft iron rivets. The arms of the other inductor *A* (Fig. 3) are alternated with those of inductor *B*, and in this illustration is shown the copper ribbon winding *C* with the ribbon terminals at *D* and *D1*. The copper winding is given a white effect because of the layers of paper for insulation between the copper. The coil has seventy-two turns. In Fig. 4 *F* and *F1* are the pole pieces against which the ends of the magnets bear, and *G* is a separator of aluminum between them.

The generation of current in an inductor magneto of this type is briefly as follows: In Fig. 6 appears a diagram of an end view with *A1*, *A2* and *A3* representing the arms of one inductor and *B1*, *B2* and *B3* of the other, the coil *C* as before being the copper ribbon. When arm *A1* is in contact with the pole piece *F1* and arm *B1* of the other inductor contacts with the opposite pole piece *F*, then the lines of force between the north and south poles *N* and *S* of the magnets pass as indicated by the line *L* through the pole piece *F1*, through the arm *A1*, through the arm *B1* and through the pole piece *F* to the south pole *S*, thus setting up current in the coil *C*. As the inductors rotate arm *A1* breaks away from pole piece *F1* and arm *B1* from pole piece *F*, and while *A1* passes over the aluminum separator *G* between the pole pieces there is no current flowing. Immediately, however, that arm *A1* comes in contact with pole piece *F* the arm *B2* has reached the pole piece *F1*, and the lines of force pass once again between the poles *N* and *S*, but from the arm *B2* to arm *A1*, thus setting up in the coil *C* a current in the opposite direction to the first impulse. In this manner as the respective arms of the star inductors contact with the pole pieces there is set up current first in one direction and then in the other. As there are three arms

Fig. 4.—End View of Inductor and Poles.

Fig. 5.—One of the F. & S. Bearings.

to each inductor and the arms alternate, the magneto gives six pulls per revolution or, in other words, six alternations or current impulses for each complete turn of the shaft.

In wiring a car with an inductor magneto of this type and a set of dry cells, the magneto and dry cell wires go direct to the switch on the coil box, thence to the primaries of the coil and thence to the timer. The magneto cannot be used with a non-vibrating coil and distributor in that no provision is made for changing the timing by altering the relation of the inductors with reference to the magneto poles while rotating, but it affords an extremely compact and reliable source of current on a car, the inductor magneto lending itself to this purpose particularly, owing to its great simplicity, whether considered from an electrical or a mechanical point of view, which adapts it to the roughest kind of service.

Seeing Europe From the Rear Seat

By Frederick K. Stearns

Near Freiburg, Germany

Wayside Shrines – Tyrol

A Road in the Tyrol

IF you would see Europe properly, view it from an automobile. Also take your own car over, likewise your chauffeur. To the seasoned autoist on the Continent this suggestion may appear superfluous, but it is my advice to the novice in European travel, based on experience gained during three extended trips. True, there are drawbacks to such a plan, but they are more than offset by the advantages, particularly if one owns a good American car. The value of having your own chauffeur is most important. Of course, he is in a measure handicapped if unable to speak the language of the countries through which he drives, but even this is far better than employing an unknown native linguist as driver, however highly he may be recommended. I have had experiences in both directions, and know whereof I speak.

The car we hired in Italy, pending the arrival of my own Packard, had as chauffeur a clever fellow, but possessed of an irresistible desire to run over everything in the animal line he could reach and travel at breakneck speed through villages. Talking had no effect on him, and even more drastic measures proved unavailing.

The chauffeur who drove us around the Italian lakes was better, but he stood in with the garage that rented us the machine, and as a result we were charged fifty per cent. more than we contracted to pay.

The French driver we engaged early in the season to do the château trip had a seemingly unquenchable thirst, taking a drink whenever opportunity presented itself, and celebrating our arrival at Blois by taking our courier with him and getting gloriously drunk.

Nor were our troubles with the chauffeurs alone, but also with the people from whom we rented the cars. With a single exception, out of the half-dozen I contracted with each attempted to deal unfairly.

The first arrangement we made was a certain sum for the car, everything to be furnished. The trouble with this was that if we wanted to go a few miles out of our way to visit a certain point the chauffeur claimed it was not in the agreement and declined to go unless tipped liberally.

The next bargain made was at so much a day for the car and so much a mile for the distance traveled. This acted exactly the opposite to the first, for the driver would keep going all day, and far into the night if we had permitted him, and took us to places we did not care for, simply to make the distance greater and his bill higher.

Another arrangement we made was to pay so much a day for the car, we to pay for the gasoline, oil, keep of chauffeur, etc. This was the most satisfactory of all, but it was difficult to keep track of the supplies used, and we had to take it for granted that the bill rendered was right.

Take Your Own American Car.

Therefore, for the one who wants the full enjoyment of a European trip extending over several months, I should advise taking your own car, if you have a good one, and your own chauffeur. For, after all, the pleasure of motoring depends more than anything else upon the man who drives, and a good, intelligent American chauffeur who does not drink is a treasure without price. You cannot value him too highly when abroad.

With this detail disposed of, Europe, with its wonderful roads and its countless points of interest, furnishes a rich field for the tourist. True, much of it has been done to death, but there are still spots off the beaten path.

One of these is the Austrian Tyrol, a district where motorists have not been seen until within recent years, owing to the fact that it is not as well known for touring as Switzerland, and the difficulty of getting in on account of the high duty exacted.

Join the Touring Club of France.

If you are traveling through Europe in an automobile you should belong to the Touring Club of France. This gives the advantage of depositing the duty money on your car for each country you may desire to visit in Paris, a *triptych* being issued therefor and the money refunded on your return. This enables one to avoid all trouble at the customs in passing from one country to another. Austria, however, was the one country which refused to co-operate with the French club, and not until the middle of this year did she come into the fold. My *triptych* for Austria was about the fourth one issued

and our car was the very first to take advantage of the new working arrangement.

In driving from Munich to Innsbruck, when we presented our papers to the Austrian official at the frontier, he at first refused to accept them, insisting that we must make the customary deposit, amounting to nearly $500, before we could enter Austria. The French gentleman who traveled with us explained in his very best German that an arrangement had been entered into between the government and the Touring Club of France, and that if the official would look over his papers he might find a notification. This he finally consented to do, and much to his own surprise found our statement to be true. With an Austrian number attached to the car, we had it kodaked as the first of any make to go into the Tyrol under the new arrangement, and proceeded on our way.

The ride from Kupstein to Innsbruck is very beautiful, but it is nothing compared with that which awaits you in the heart of the Tyrol Mountains. We left Innsbruck the morning following our arrival, and made Brenner pass, which is easy of ascent, being only about 6,000 feet high. We made it on high speed, owing to good roads and the absence at that hour in the morning of other vehicles, but noticed that some of the best French cars, as well as others, went up on slow speed.

Lunching at Bozen, we obtained our first and only view of the magnificent Dolomites. Had we had more time at our disposal we would have gone further south, even into Italy, so as to visit these mountains and the beautiful district in which they lie. However, we went on to Meran, where we stopped for the night. The trip from Innsbruck to Meran is one of the finest in all Europe, and was excelled in beauty only by our next day's run to Bregenz. We ran within a few miles of the Stelvio pass, which is the highest roadway in Europe, but as we were not going that way did not take it. Another pass we encountered between Landeck and Feldkirch, while not so high as the Stelvio, was considered very dangerous by travelers, because of the excessively sharp hairpin and corkscrew curves on approaching and descending the mountains. The working of our brakes left nothing to be desired, however, and we got through safely, bringing our short but highly interesting trip through the Tyrol to an end.

Tyrol Trip Has No Equal.

To anyone who appreciates fine scenery and enjoys traveling through mountains the Tyrol trip has no equal. If more magnificent scenery exists anywhere, I have never encountered it. The towering, snow-capped mountains, the rock-ballasted roads, as a rule kept in excellent condition, the queer roadside shrines encountered at frequent intervals, the constantly changing panorama, leaves nothing to be desired unless it might be that more time could be spent here, and sends the traveler away with pleasant memories. In addition to the attractiveness of nature, the picturesqueness of the villages and the quaintness of the people in the Tyrol rounds out a picture of exceptional interest and one which the average traveler misses.

From Bregenz we drove to Freiburg, Germany, along the shores of Lake Constance and through the Black Forest. The roads are perfect and the scenery fine, alternating between views of the lake and those of the tree covered mountains. After a couple of days spent in motoring over the wonderful hills and through the vast forests around Freiburg we crossed into France by way of the Alberger pass, the border line being located on the mountain. This pass, although not so well known, is much more difficult than either of those we made in the Tyrol, yet we had no difficulty in ascending on our high speed and only had to shift in coming down the mountain, where we were in close quarters with a diligence.

Our next day's run was to Nancy, where we spent the night, and then direct to Paris, about two hundred miles, on the following day. This finished our second tour of the Summer, which in length was somewhat shorter than our first, although it embraced 2,000 miles. Add to these two trips 1,000 miles in England and our trips around Naples and Italy, along the Riviera and about the Italian lakes and it would make in round figures 6,000 miles. At no time did we try to make exceptional speed, journeying leisurely in an endeavor to see the towns as well as the country. We succeeded, too.

For three months prior to taking the Tyrol trip we motored through Europe, starting from Liverpool and doing much of England, which, although intensely interesting, is too well known to Americans who have motored abroad or, in fact, traveled in other ways to call for extended mention. A couple of days in London at the close of the English tour was sufficient to again give us the motor fever, and we drove to Folkestone, crossed the channel to Boulogne, and started at once for Paris.

Along the Seacoast of France.

After a week or so there, during which time we used our motor constantly, we started for an extended trip around the seacoast of France. At Trouville, one of the most popular seashore places in France, we were the only guests at the im-

A narrow Street-Southern France

A Native haycart - Tyrol

In the Tyrol

mense Noire Roches. Nevertheless, we were entertained as graciously as if we had been a royal family and the hotel had been "full up," as they put it abroad, instead of empty.

All of which is characteristic of this country, where good living is counted the chief aim of existence, and where it is a joy to travel. Nowhere in France have I ever found anything but good food and clean beds. In the smallest country village, where apparently there was not a visitor a day at the inn, there would always be prepared the most palatable *dejeuner* on the shortest possible notice, and there were always clean rooms for travelers.

As for Spain—but that is another story.

One incident worthy of mention reflects the sentiment of your Frenchman, be he of high or low rank. At one little place where we stopped for luncheon the *chef* was owner, manager, cook, and grand factotum. He spoke a little English, and informed me that he spent two years in America as *chef* for a well-known Washington family.

What the Chef Said of America.

"America is one gran' country," said mine host, shrugging his shoulders, "but ze people, ah! Zey are w'at you call ze nice people, but zey are not artistic. Zey know not ze value of ze fine cooking, only eat, eat, eat. Cooking is ze fine art, like music an' ze drama, but ze American he does not t'ink so. So I save up my money an' come back here, where fine cooking is appreciated. M'sieur, America is ze gran' country, but I had sooner be ze inn keeper in zis leetle village where ze people know how to eat properly zan wan gran' *chef* in ze Washington."

Only at Mont St. Michel were we doomed to disappointment, and that possibly because our expectations had been pitched too high. The *omelette soufflé* of Madame Poulard is more celebrated through Burton Holmes' lecture than in reality. Better omelettes are made at plenty of places in France and even at home than the present Poulard family turns out. Nevertheless, this interesting spot, now an island, except for the artificial roadway built to it, is well worth a visit.

The hotel here, like the one at Amalfi, Italy, is built away up in the air on rocks, and the climb to get to your bedroom is all the exercise one needs for an entire day. The view, however, is well worth the effort. It is here that the tide comes in faster than a horse can trot, but our guide, seeing we were motorists, tried to flatter us by saying that an automobile could probably beat the tide. We decided not to do any investigating along this line.

The entire trip along the French coast through Brittany, with its quaint villages and quainter natives, and over into Spain, is a journey never to be forgotten, as is the ride through the chateau country of France. The latter part of this trip is through a district where for miles the roadway goes by caves and cellars in the rocks in which wine is stored.

In the Heart of the Champagne Country.

Equally interesting, even to the total abstainer, is a journey through the country around Reims, in the heart of the champagne country, and where many of the most noted manufacturers of this wine have their cellars. We visited those of Pommery, which are reached by a flight of 200 or more steps down into the earth and a walk through tunnels and caves of chalk. We apparently walked a half mile, getting enough of it in this time, but our guide assured us that there were many miles of cellars, taking the upper and lower stories, and that millions of bottles of champagne were stored there.

Volumes could be written on our experiences in France, in Germany, in Austria, in Spain, in the Tyrol, in Italy and in England, but space and time forbid.

When you remember that France alone has 40,000 miles of roads whose equal is seldom encountered in America, and that conditions in the other countries enumerated are much the same, it is not difficult to understand why people who want to motor go as far as Europe.

Touring there is taken much as a matter of course. At Liverpool we met a man just starting out on a drive to Madrid with as much unconcern as though he were simply going from Detroit to Buffalo.

At Jaffa we saw Charles J. Glidden, of Boston, who has motored around the world and was finishing up a 60,000-mile trip, his being the first automobile that ever entered the Holy Land.

One meets all sorts of enthusiastic motorists who eat, drink, and sleep in their cars. To such my little experience will, of course, be of no benefit. But, be he seasoned motorist or amateur, a tour of Europe is bound to possess educational value, not the least as showing Americans the possibilities at home in the way of good roads.

THE AUTOMOBILE CALENDAR

AMERICAN.

Shows and Meetings.

Dec. 31-Jan. 7...—New York City, Grand Central Palace, Ninth Annual Automobile Show, conducted by the American Motor Car Manufacturers' Association, with Exhibits by the Importers' Automobile Salon, Inc., Alfred Reeves, General Manager, 29 West 42d St.

Jan. 16-23.....—New York City, Madison Square Garden, Ninth Annual National Show of the Association of Licensed Automobile Manufacturers. M. L. Downs, Secretary, 7 West 42d St., New York City.

Feb. 6-13.....—Chicago Coliseum and First Regiment Armory, Eighth Annual National Exhibition, National Association of Automobile Manufacturers. S. A. Miles, Manager, 7 East 42d St., New York.

Mar. 7-13.....—Buffalo, Second Annual Power Boat and Sportsman's Show, Convention Hall, Dal H. Lewis, manager, 760 Main Street, Buffalo, N. Y.

Races, Hill-Climbs, Etc.

Oct. 10.....—Providence, R. I., Narragansett Park, Race Meet, Rhode Island, Automobile Club.

Oct. 10.....—Philadelphia, Founders' Week Stock Chassis Race, 195 Miles, Quaker City Motor Club.

Oct. 10.....—Long Island Motor Parkway Sweepstakes, Conducted by Vanderbilt Cup Commission.

Oct. 10.....—Providence, Narragansett Park, Race Meet. Rhode Island Automobile Club.

Oct. 10.....—Morristown, Madison, Chatham, N. J., Automobile Carnival and "Tour Around the World," under Y. M. C. A. auspices.

Oct. 24.....—Vanderbilt Cup Race, Long Island Course, auspices of Vanderbilt Cup Commission.

Oct. 31.....—Philadelphia, Sixth Annual Run of Automobile Club of Philadelphia for the Brazier Cup.

Nov. 26.....—Savannah, Ga., Grand Prize Race, Savannah Automobile Club.

FOREIGN.

Shows.

Oct. 11-18.....—Paris, International Congress and Public Exhibition on Roads and Road Making for Modern Locomotion, French Ministry of Public Works.

Nov. 13-21 .....—London, Olympia, Seventh International Motor Exhibition.

Nov. 28-Dec. 13.—Paris, Eleventh Annual Salon de l'Automobile, Grand Palais, Automobile Club of France (Pleasure Vehicles, etc.)

Dec. 20-28.....—London, Stanley Show, Agricultural Hall.

Dec. 22-29.....—Paris, Eleventh Annual Salon de l'Automobile, (Commercial Vehicles, etc.)

Jan. 16-25.....—Brussels, Show Organized by Belgian Chamber Syndicate, Palais du Cinquantenaire.

Races, Hill-Climbs, Etc.

Oct. 11.....—Berlin, Germany, Gordon Bennett Balloon Race, Aeronautical Club of Berlin.

FIFTEEN OUT OF TWENTY HOOSIERS HAVE PERFECT SCORES

INDIANAPOLIS, Ind., Oct. 3.—The two days' reliability run given by the Indianapolis Automobile Trade Association, Thursday and Friday, developed into one of the worst gruelling contests automobiles have ever had over Indiana roads. Despite this fact, fifteen of the twenty-six cars entered finished perfect.

It had been predicted that not more than 20 per cent. of the cars entered would finish with perfect scores, and this probably had a tendency to keep down the number of entries. The roads were ideal for the kind of contest it was, offering long stretches of good highways where great speed was possible, the highest hills in Indiana to test the hill-climbing abilities of the cars, and sharp turns and dangerous stretches of roads to try the nerve of drivers and to call for most cautious handling of the cars.

The cars were turned over to the technical committee Wednesday afternoon and were parked on the west side of University Park for the night after, having been inspected and sealed. The first car left Indianapolis at 7 A. M. Thursday, and the others followed at one minute intervals.

The run Thursday was to French Lick, a distance of 131.2 miles and the roads were much better than on the return trip, which was 122.2 miles in length.

Practically all of the penalties were for things of minor importance, only one or two of the difficulties were anything that would interfere with the actual running of the car. Loose parts, lost bolts, etc., were responsible for many of the penalties. The following is the table of the run, including nature of penalties:

No.	MAKE	Driver	Class	H.P.	Price	Seals Broken	Penalizations	Final Score
1	NATIONAL	John Aitken	A	50	$4,200	None	None	Perfect
2	NATIONAL	Thos. Kincaid	A	50	3,700	None	None	Perfect
6	MARMON	H. G. Shafer	A	50	3,750	None	None	Perfect
7	MARMON	H. Stilman	A	50	3,750	None	None	Perfect
10	PREMIER	Harry Hammond	W	30	2,600	None	None	Perfect
11	PREMIER	Henry Letsinger	A	30	2,600	None	None	Perfect
12	PREMIER	Miss Elizabeth Love	A	30	2,700	None	None	Perfect
14	PREMIER	Frank Morrison	A	30	2,600	None	None	Perfect
4	STUDEBAKER	F. B. Willis	A	30	3,500	None	Left rear fender loose	2 points
9	AMERICAN	Fred Tone	A	50	3,750	None	Towed to start motor	5 points
8	HAYNES	Robert Murden	A	60	3,750	None	Foot brakes not working	10 points
5	PACKARD	Chas. Stuttz	A	30	4,200	None	Towed to start motor; starting crank bent	11 points
3	NATIONAL	Harry Moore	A	50	3,700	None	Two plates on front spring broken	16 points
18	RAMBLER	Ted Collier	B	32	2,250	None	None	Perfect

28	MAXWELL	O. J. Gronendyke	C	12	850	None	Reverse not working; carbureter adjusted. Broken secondary wire	19 points

SINGLE-CYLINDER SIZAIRE WINS COUPE DES VOITURETTES

PARIS, Oct. 1.—That it is not necessary to have cars of 120-horsepower to provide a good auto race is proved by the results of the Coupe des Voiturettes, run off last Sunday, over a distance of 248 1-2 miles, near Compiegne. Naudin, on a one-lunger Sizaire-Naudin limited to 100-millimeters (3.9 inches) bore, covered the distance in 5:14:8, being an average of 47 1-2 miles an hour. Although it is not such fast going as was witnessed at the Dieppe voiturette race, the performance is more remarkable, for the Compiegne circuit necessitated at least 200 changes of gear or important reductions of speed for each of its

Of the 17 cars to finish, the first six were driven by single-cylinder engines of 3.9 inches bore. Martini, the only foreign firm in the race, finished seventh, eighth and tenth with four-cylindered cars of 2.5 millimeters bore. At Dieppe the maximum bore for this type of engine was 2.4 inches; even with the extra allowance, however, it was manifest that there was a decided inferiority in power produced by the multiple compared with the single cylinder engines. Martini, however, had the satisfaction of being awarded the special prize for the best performance by cars most nearly approaching commercial models, and of being the only firm besides Sizaire-Naudin to finish with a full team.

Not even the Sizaire-Naudin engineers would maintain that the winning trio corresponded with commercial models. Bore having been limited to 3.9 inches, most firms were content to adopt a stroke of 7 inches; two firms went as high as 7.8 inches, but Sizaire-Naudin took the bold step of lengthening the stroke to 250 millimeters, which to give the exact English equivalent is 9.84 inches. It is the greatest ratio of stroke to bore ever adopted on an automobile, and was, in the opinion of the experts, ridiculously exaggerated; results, however, proved conclusively that the Sizaire-Naudin people were right. To show that the long-stroke motor is the most advantageous, it is only necessary to mention that the order in which the cars finished was in direct ratio to the length of their stroke. Sizaire-Naudin finished first with 9.8 inches stroke, Lion-Peugeot was second with 7.8 inches, Corre and La Joyeuse followed, each with 6.2 inches stroke, and Alcyon was behind with 5.9 inches.

Tire troubles were light, the first six being shod by Michelin. Bosch supplied the high-tension magnetos of the first four cars. No car made use of storage batteries for the supply of electric current. The following is the order in which the 17 out of 31 starters finished the race:

Car.	Driver.	Time.
Sizaire—Naudin,	Naudin	5:14:8
Average 47 1-2 miles an hour. Michelin tires, Bosch magneto.		
Sizaire—Naudin,	Sizaire	5:21:20
Lion—Peugeot,	Goux	5:43:50
Sizaire—Naudin,	Lebouc	5:43:53
Corre,	Collomb	5:47:29
La Joyeuse,	Taine	6:14:49
Martini,	Sonvico	6:19:29
Martini,	Beck	6:19:43
Guillemin Le Gui,	D'Avaray	6:35:13
Martini,	Richard	6:36:16
Guillemin Le Gui,	Riviere	6:39:48
Lion—Peugeot,	Boillot	6:40:39
Alcyon,	Rolean	6:54:48
Werner,	Gaesler	6:57:22
Aries,	Meau St. Marc	7:03:16
La Joyeuse,	Schweitzer	7:03:41
Truffault,	Giraud	7:33:02
Regularity Prize for team work.		Total Time 3 Cars.
Sizaire—Naudin		16:19:21
Martini		19:15:28

SHAFT-DRIVE NOW UNIVERSAL.

With the advent of the 1909 show season, it is safe to say that a review of the models for the coming season will reveal the fact that there are now very few American makers devoting their energies exclusively to the production of a side-chain driven type of car. The transition from chain to shaft drive has been more or less gradual, but that the process is now practically complete is evident from the capitulation of those designers who have consistently adhered to the chains up to the very last. Nor is their surrender to be regarded as evidence of their conviction that the shaft-driven car is superior; it is but another instance of the fact that the public demand is far stronger than the dictates of technical requirements, or the designer's preference. If buyers will have a shaft-driven car, there can be no alternative than to meet the demand.

In some cases it is noticeable that makers of high-powered cars have abandoned the chain-drive entirely, while in others only the lighter cars turned out are of the shaft type and the chains are still retained on the more powerful models. There is at least one instancce in which the maker has frankly stated that his preference for the chain-driven car is as strong as ever, his bow to the inevitable taking the form of an option to the purchaser on either type. While the shaft drive has not only proven practical from the first, as well as highly desirable from every point of view, the preference for chains on cars above a certain weight and power is very well founded, and it seems doubtful if the chain-driven car will ever disappear entirely. It is quite probable, however, that the shaft will, sooner or later, displace the single chain now employed on some light cars, so that everything below a certain power will be of the now practically universal type.

* * *

CONTESTS WHICH TELL SOMETHING.

In the Coupe des Voiturettes, held in France, a single-cylinder car averaged nearly 50 miles an hour over a course only fairly good. In the so-called "Four-Inch" race of the British club, held over twisting narrow roads on the Isle of Man, the cars averaged fully as well, though several of them were capable of eighty to ninety miles an hour over a real racing course.

Once upon a time—and not very long ago—a "juggernaut" which could travel in and around a mile-a-minute was rated in the top flight of speed. Now a single cylinder can do almost as well. Truly there has been a wonderful advance in the engines of automobiles, and the end is not yet.

Speed competition of the present, to have a practical value, unquestionably tends to contests for limited engines constructed for cars which are suitable for the average buyer, who demands reasonable speed at a reasonable cost. The fastest flight of which an automobile is capable may be seen in the forthcoming Vanderbilt Cup race, with abnormal engines possessing power in excess and which no sane driver will utilize to its full capacity. Having gone far beyond the limits of sanity, it is high time that the hazards of competition be modified to a degree which will bring the sport back to the realms of reason and at the same time make it of value to the purchasers of automobiles. It is probable that the 1908 Vanderbilt race will be the last of its kind, and here's hoping that no catastrophies will mar what should be the most spectacular automobile racing ever supplied.

* * *

SPORT WHICH SADLY BELIES THE NAME.

In the early days of automobiling, when horsepower was both moderate and uncertain, the circular tracks built for horse racing answered fairly well for motor racing. Then, the danger was not excessive. Now, the risk is abnormal. Of slight, if any, worth to the maker or the user, and with faults which outweigh any advantages claimed by its most ardent supporter, the finish of high speed automobile racing on horse tracks is near at hand. A perusal of the accident chapter of the Brighton Beach "24" tells its own story, and if the directors of the A. A. A. accepted the views of its president, William H. Hotchkiss, there would be no further sanctioned racing of this kind by the national body of the country. With the big powered cars driven anywhere near their capacity the danger is beyond the point of sanity. It is either this or just plain "hippodroming"—one is criminal, and the other is "fake" racing. Let us end it—at least in any sanctioned form.

Storm Center of Long Island Motor Parkway, Where Most Complete Arrangements Have Been Made for Contestants and Spectators.

PARKWAY SWEEPSTAKES NEXT, THEN THE VANDERBILT

SIXTEEN entries are known to have been made for the Vanderbilt Cup race. It may be that the resolution of the Racing Board as to those drivers that competed in the unsanctioned meet at Brighton Beach on September 11 and 12, particulars of which are set forth elsewhere in this issue, may reduce the present list by one or two, or perhaps, which is more probable, result in an increase should the suspended ones make their peace with the racing authorities. Pending the readjustment of the standing of the outlaw pilots, the Vanderbilt Cup commission has delayed making public the exact status of the entry list for the Long Island classic.

The nominations for the Vanderbilt race now amount to 10 American and six imported cars, the previous entries being made up of three Mercedes, two Knoxes, a Matheson, a Brasier, a Mora, a Chadwick, an Acme, a Thomas, an Isotta and a Renault.

The Vanderbilt Cup Commission offices have been removed from Manhattan to the Garden City Hotel, where Chairman Thompson will make his headquarters until after the race. Reservations for seats, boxes, and parking spaces may be obtained at the city offices of the Commission, 437 Fifth avenue.

Indications point to a big novel, and interesting struggle for the Sweepstakes, which will inaugurate racing on the Long Island Motor Parkway next Saturday. The course was so far completed that daylight practise over it began yesterday.

The cars will be started with the lowest-priced cars in the lead followed by the other classes in price order, the order of the start of the various sweepstakes being Nassau, Jericho, Garden City, Meadow Brook, and Motor Parkway. Each car will bear the initial of its own particular sweepstakes.

Hartford Club at the Vanderbilt Cup.

HARTFORD, CONN., Oct. 5.—The Automobile Club of Hartford has abandoned all hope of conducting either a hill climb or a 24-hour race this Autumn. Inasmuch as the Vanderbilt Cup race is almost due, it was deemed expedient that that event furnished enough excitement for the club members. A large delegation from the local club will visit the Cup race, and a good parking space has been secured that will accommodate about 50 cars near the grandstand. The Hartford delegation will have their own tents, and breakfast will be served on the grounds.

SUSPENDED DRIVERS GET ANOTHER CHANCE.

Action in the matter of drivers who competed in the unsanctioned meet at Brighton Beach, September 11 and 12, was taken by the A. A. A. Racing Board at a meeting held last Saturday. Previous to their participation in the races in question, all drivers were notified that their competition would mean disqualification. Since the race, however, several of the suspended drivers with mounts in prospect for the Vanderbilt and Sweepstakes have declared that they competed under a misapprehension. The Board leniently decided to take them at their word and give them a chance to start anew with a clean slate by the adoption of the following resolution:

WHEREAS, Various persons have participated in races coming within the jurisdiction of the American Automobile Association, but for which no sanctions had been granted by that association, and, whereas, it appears that from the statement of some such persons that they participated in the said races under a misapprehension; be it

RESOLVED, That in the cases of such participants as were under the misapprehension referred to, their disqualifications pursuant to the rules of the Racing Board of the American Automobile Association, be suspended to the extent of enabling them to participate in any race already sanctioned by the Racing Board, upon such persons filing a statement to the effect that they shall not hereafter participate in any manner or form in any race claimed by the association to be within its sole jurisdiction and for which no sanction has been granted by the Racing Board of the American Automobile Association.

FOURNIER IS TO DRIVE AT SAVANNAH.

Quite a batch of foreign entries were received by the Automobile Club of America before the preliminary nominations closed last Thursday. Most noteworthy to Americans was the fact that Henri Fournier, who inaugurated high-speed sprinting in this country on the Coney Island Boulevard by setting up an initial world's mile record of 51 4-5 seconds, and won the Paris to Berlin race, would resume racing and return to this country to pilot one of the two Itala cars named by the Italian club. The other will be driven by Cagno.

Hautvast will pilot one Clement-Bayard, and Rigal another, while Szisz will once more be at the wheel of a Renault.

The complete list of entries to date, with another month yet to come before entries finally close, consist of the following: Fiat, Nazarro; Fiat, Wagner; Fiat, De Palma; Benz, Hemery; Benz, Hanriot; Benz, Earle; Mercedes, Salzer; Mercedes, Poege; De Dietrich, Duray; Clement-Bayard, Rigal; Clement-Bayard, Hautvast; Renault, Szisz; Itala, Fournier; Itala, Cagno; B. L. M., R. W. Buckley; American Locomotive, L. J. Bergdoll; Matheson, foreign driver; Acme, Patschske or Rodgers; Lozier, Michener.

The Savannah light car race has 14 entries to date, consisting of two Gyroscopes, three Maxwells, three De Dions, three Buicks, an American Aristocrat, a Chalmers-Detroit, and a Cameron. The latter is an air-cooled car from which great results have recently been obtained.

Maxwell 12-Cylinder 180-Horsepower Racing Car.

This powerful racing craft at Ventnor Beach, near Atlantic City, N. J., October 1, covered a mile in :31 1-5 seconds, at the rate of 116 miles an hour.

CANADIANS GREET AUTO RACING WARMLY.

MONTREAL, Sept. 28.—Canadians were given their first automobile track meet last Saturday and Sunday at Delorimier Park half-mile track. It was held under the auspices of the Automobile Club of Canada. R. M. Jaffray, promoter of the Montreal show, managed the meet for the club, though efficient assistance was rendered by President Duncan McDonald and Secretary George A. McNamee.

That Canadians are alive to the competitive possibilities of the automobile and are eager to patronize motor car racing is proved by the attendance on Sunday reaching 16,000 paid admissions.

The record trials and competition of Barney Oldfield and Charles Soules with Barney's Stearns "six" and "four," Walter Christie, and Charles Burman with the McLaughlin Buick were the chief crowd-drawing attractions. Christie showed a mile in 1:10; Soules, 1:14, and Oldfield, 1:15. Christie also made a half mile in 34 seconds. Burman made practically a clean sweep of the open stock car events, in which he was eligible to compete. The five-mile championship of Canada for 20 to 35-horsepower cars fell to L. D. Robertson's Comet, in 6:44. Robertson also beat Tedford, Stearns, in a mile match in 1:19.

DETROIT DEALERS TO PROMOTE 3 DAYS' TEST.

DETROIT, Oct. 6.—With the success of last year's event still in mind, the Detroit Automobile Dealers' Association has planned a far more difficult endurance run for next month. November 5, 6 and 7 are the dates set. The first day's run will be to Saginaw and back. The second day the course will be triangular, Adrian and Jackson being included, with Detroit as the terminus. The third day's run will be to Lansing and back.

Each night all cars will be parked in the streets near the Hotel Tuller, a strict guard being maintained. Oil and gasoline will be furnisbed under inspection, and at the end of the tbird day's run a committee will make a technical examination of each car to determine exactly what it has accomplished, each observer's report also being taken into consideration.

Entrants have been divided into three classes, the handicapping system providing for the smaller cars to start first, medium-powered ones later, and the largest ones some time after. Several valuable trophies have been offered by the Detroit Auto Dealers' Association as prizes.

CLEVELAND RELIABILITY POSTPONED.

CLEVELAND, Oct. 5.—The Cleveland Automobile Club decided to postpone its three-day reliability run, scheduled for October 7, 8, and 9, because of a conflict in dates with the contest of the Chicago Motor Club. There is a possibility that it cannot be held until the first part of November.

FRENCH MOTORDROME IN CHATEAULAND.

PARIS, Oct. 1.—France has been considering the advisability of a permanent racing course for three years, and is still considering. At the present moment the Auvergne track has fallen back a little in popular estimation, for it has been discovered that the ideal spot is in the Chateau country, by the banks of the limpid Vienne river, near Tours, and in the neighborhood of Azay-le-Rideau and Chenonceau.

The proposed course has been visited by a commission of the Automobile Club of France and pronounced to be all that can be desired. Geographically the situation is excellent, the course being in the Garden of France, in a land of good roads, and with adequate railroad facilities. After running along the banks of the Vienne, the proposed course skirts the Ruchard camp and the Chinon forest, giving a total distance of 12 to 18 miles as desired, without any railroad or cross road. The land being on a low hillside, the course would have gentle grades with absolute straightaways of four to five miles. The financial aspect of the question remains to be discussed. Local opinion is strongly in favor of the scheme.

A NEW 200-H.P. RIVAL FOR DIXIE II.

PORTCHESTER, N. Y., Oct. 5.—There is now nearing completion in the shops of the Jencick Motor Manufacturing Company here a new six-cylinder vertical 200-horsepower motor of the automobile type, which has been designed to form the power plant of the *Richard Croker, Jr.* The hull is being built by Herreshoff, at Bristol, R. I., and the boat when completed is to be pitted against the *Dixie II.* at the motor boat races to be held at Palm Beach next Winter. The motor has been designed by Stephen Jencick, and the builders are to receive a liberal bonus, over and above the contract price, for bringing its total weight down to 1,800 pounds, which, however, must be done without sacrificing strength or ability to run under full load for an extended period. One means of doing this is to be found in the employment of McAdamite for the crankcase; other features of note are the use of Hess-Bright bearings on the camshafts, and the triplex plunger pump provided to circulate the cooling water.

A NEW PITTSBURG-PHILADELPHIA RECORD.

PHILADELPHIA, Oct. 2.—George Salzman last Saturday in a Thomas light six succeeded in beating by nine minutes the previous record between Pittsburgh and Philadelphia of 14 hours 1 minute, held by S. D. Waldon, in a packard "30," carrying five passengers in all. Salzman's elapsed time was 13 hours 52 minutes. He claims, however, an actual running time of 11 hours 37 minutes, setting up 2 hours 33 minutes loss of time, due to gasoline and tire troubles, toll gates and misdirections.

The 76-mile run from Lancaster to Philadelphia was made in a dense fog. Four and a half miles were added by going to York by way of Hanover and three more by misdirection on the Littleville road, making 7 1-2 miles in excess of the Packard run of 302.4 miles, or 309.5 miles in all covered by the Thomas.

FORT GEORGE HILL CLIMB, SATURDAY OCT. 17.

The New York Automobile Trade Association has decided to hold a climb up Fort George hill Saturday, October 17. President Frank Eveland has appointed Richard Newton, Charles P. Skinner, C. H. Larson, and Walter R. Lee a contest committee to formulate the rules and conditions which will be in force. The proposal is that the classes be divided not only as to the cost, but also as to horsepower, which should bring about some close races.

BRITISH CONCERN ADOPTS KNIGHT MOTOR.

LONDON, Oct. 1.—The Silent Knight patents, which were adopted by the Daimler Motor Company, have also been arranged for by Minerva Motors, Ltd., for 1909.

DRAWING FOR SPACES IN "PALACE" SHOW.

Applicants for space in the Grand Central Palace show were scheduled to draw for their spaces to-day, the A. M. C. M. A. members in the morning, and the others in the afternoon. Space allotments for the importers have already been determined upon and made. When the applications for space closed on October 1 over 100,000 square feet had been applied for, and only 70,000 square feet are available for exhibition purposes.

At the session Tuesday the Regal Motor Car Company, of Detroit, was admitted to membership.

The question of international racing rules was referred to the contest committee with power to make recommendations.

In attendance at the meeting were: Chairman Benjamin Briscoe, Maxwell-Briscoe Motor Co.; James Couzens, Ford Motor Co.; C. G. Stoddard, Dayton Motor Car Co.; R. M. Owen, Reo Motor Car Co.; H. O. Smith, Premier Motor Mfg. Co.; Charles Lewis, Jackson Automobile Co.; S. H. Mora, Mora Motor Car Co.; W. H. Van Dervoort, Moline Automobile Co.; G. Vernor Rogers, Mitchell Motor Car Co.; and Alfred Reeves, general manager.

WILBUR WRIGHT WINS A $100,000 CONTRACT.

LE MANS, FRANCE, Oct. 6.—Wilbur Wright to-day carrying a passenger remained in flight for 1 hour 4 minutes 29 seconds, thus fulfilling all conditions of the contract signed by him and Lazare Weiller, representing a syndicate, which agreed to pay Mr. Wright $100,000 in return for patent rights in France and the colonies. The condition required two flights within a week with a passenger, for at least a distance of 50 kilometers.

Record Balloon Ascension Lasting 37 Hours.

PARIS, Oct. 6.—The 1908 Grand Prix race, organized by the Aero Club of France, to-day was won by Georges Blanched, who, in the balloon *Centaure*, completed an ascension lasting 37 hours, thus winning a cash prize of 1,500 francs and various medals and objects of art. He traveled exactly 550 kilometers, and landed near Allois.

TO TEST NEW JERSEY'S AUTOMOBILE LAW.

PATERSON, N. J., Oct. 5.—Frederick J. Kane, of Woodhaven, L. I., driving a Packard automobile which did not carry a New Jersey registration number, this afternoon, was arrested for a violation of the present Frelinghuysen law. The case is the test case planned by the Associated Automobile Clubs of New Jersey, and when arraigned before Recorder Carroll, Mr. Kane was represented by former Attorney-General John W. Griggs. The hearing was set for October 19, after which the case will be taken to a higher court. Under the present law, though an owner may be registered in his home State, he is also required to do likewise when he enters New Jersey.

AUTO MAKERS INVADE CARRIAGE EXPOSITION.

This week the annual exposition of the Carriage Makers' Association has been in progress in the Grand Central Palace, New York City, and one of the first things noticed by visitors is the fact that no less than fourteen different makes of automobiles are on exhibition. The following cars are exhibited: Rambler, Ford, Autocar, Gyroscope, Marmon, Glide, and Brush; and the Holsman, Anderson, Economy, Reliable, Dayton, Schacht, Kiblinger, and Mallon buggyabouts.

WHITE MOUNTAINS TOURISTS INCREASING.

BRETTON, N. H., Oct. 5.—The great and growing popularity of the White Mountain region as a touring district is evidenced by the number of cars registering at the Bretton Woods garage. In 1907 there were registered 800 cars. This year the increase has been nearly 50 per cent., for the number rose to 1,137 for the present season. With the low estimate of four passengers per car, it means that at least 3,200 people toured to Bretton Woods in 1907 and 4,548 in 1908.

NORTHERN MERGED INTO E-M-F COMPANY.

DETROIT, Oct. 5.—During the past few month much gossip has been in circulation concerning the proposed disposal of the Northern Motor Car Company. The reports have been very conflicting, but it is now announced directly from the Everitt-Metzger-Flanders Company that it has taken over the Northern concern in its entirety; the two factories at Detroit and Port Huron and the cars now on hand—about 100 of the two-cylinder models. The capital stock of the Everitt-Metzger-Flanders Company has been doubled, so that it is in the million-dollar class.

Walter B. Flanders, general manager of the E-M-F Company, states the the acquisition of the Northern will in no way change the plans of his concern. "Except we'll be able to increase our output and inaugurate a plan I have long wanted to put in force. That is, a separate factory for the production of replacement parts for all previous models of Wayne and Northern cars, as well as for all future E-M-F models."

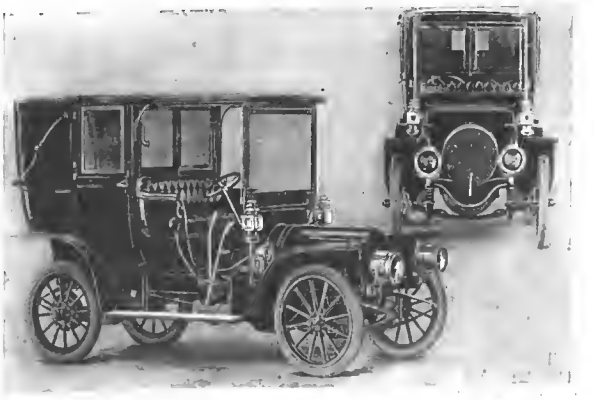
DYNAMO RUSHMORE IS ON THE WARPATH.

PLAINFIELD, N. J., Oct. 5.—Samuel W. Rushmore, he of dynamo fame, has all Plainfield by the ears through his novel and aggressive campaign against what he claims to be his outrageous tax assessments. He has raised above his factory a conspicuous illuminated sign depicting a ring politician with hat cocked on one side, cigar atilt, and monster diamond pin. The sign bears the legend: "Tremendous Taxes for easy Plainfielders. Easy taxes for men in the ring. Rushmore tax books for 'Who's Who, and Why.'"

For the past three weeks Mr. Rushmore has had five men copy the Plainfield tax registers for his "Who's Who, and Why."

FRANKLIN TO SPECIALIZE ON CLOSED CARS.

Up to the beginning of the present year, the builders of the Franklin air-cooled cars have devoted little or no attention to the construction of closed bodies for their cars, although for several years past they have maintained a complete body-building shop as a part of their automobile plant. For the coming season, however, they have decided to bring out five closed models, one of which will be an inside-driven brougham for two passengers, on the 18-horsepower, four-cylinder chassis, to list at $2,250, and a six-passenger special town car, to be known as Model K-2, which will have as its foundation the special Franklin cab chassis. This is also equipped with an 18-horsepower motor, designed for the hardest kind of town and suburban service. The other two models are both of the landaulet type, one, a four-passenger 18-horsepower car, probably being the smallest of its kind on the market; it lists at $2,500, while the larger car of the same type is equipped with a 28-horsepower motor and lists at $4,000. The limousine will be the largest closed car of the Franklin line and will be built on the six-cylinder, 42-h.p. motor.



Side and Front Views of 1909 Franklin Model D Landaulet.

News in General

Two of the Motor Parkway Sweepstakes Performers.

The first to establish headquarters for the Sweepstake events which are to take place this Saturday at the opening of the Long Island Motor Parkway, was the Dayton Motor Car Company, which secured quarters at the estate of Albert Gifford, at Westbury. The camp is in charge of Joseph Tracy.

Will Outlast a Locomotive.—"Given no more than the ordinary care by the average owner a Pierce Arrow will outlast any locomotive in use to-day," says J. L. Osgood, a consulting mechanical engineer of Buffalo. Continuing, he said: "I know the Pierce cars thoroughly, and I have had more or less to do with them since the first ones were manufactured, and in saying this I do not make any qualifications of any kind. Locomotives are, of course, subjected to strains, but these are more than offset by the road strains automobiles are called on to withstand in ordinary usage. For instance, one of the strains that tells most on a locomotive is encountered when it rounds a curve at high speed. Even then, however, it has the advantage of a banked track. The automobile encounters sharper curves and has to negotiate them on an almost level roadway. Again, the locomotive is in the hands of a trained mechanic, while the automobile is often driven and cared for by a man who has only a superficial knowledge of machinery and its needs. Yet, with all the advantages of care a locomotive has over an automobile, the latter will outlast the former, and I have no hesitancy in saying that a Pierce Arrow should give good service for fifteen years."

"Rapid" Trucks in Demand.—The reports from Pontiac, Mich., the home of the Rapid Motor Vehicle Company, makers of commercial vehicles, shows that this company is making great preparations to handle its business for 1909. Besides the new additions that are just being completed, the company is starting work on an office building to take care of the increased business in that part of the organization, and H. G. Hamilton, the general manager, says that if the orders continue to come at the present rate they will soon have to start on another factory. W. A. Sommerville has been added to the staff as advertising manager, and T. P. Myers, formerly of the advertising department, has been made general sales manager.

Herreshoff Motor Company.—The Herreshoff Motor Company is the title of a new concern just established in Detroit to undertake the manufacture of automobiles. C. F. Herreshoff, one of the sons of the famous yacht designer, and until recently engineer in charge of the American & British Manufacturing Co., Bridgeport, Conn., is the head of the new company and will probably give his name to the product. The latter is to consist of three cars, a 22, 25 and 40-horsepower machine, the power plants of which will probably be built in Bridgeport. The new cars will doubtless be revealed in the East for the first time at the coming show of the A. M. C. M. A., in the Grand Central Palace in January.

Motorcycle Makers Organize.—The importance of the motorcycle has increased until there are at present more than twenty manufacturers of two-wheelers in this country. The makers now come out with the announcement that they have gotten together and organized under the name of the Motorcycle Manufacturers' Association, with everything pointing to the election of George M. Hendee, of Springfield, Mass., as president. The new association appointed a show committee at its first meeting and plans are already under way for a complete exhibit of motorcycles at the Madison Square Garden show in January, with the Chicago and Boston shows to follow.

Rambler Makes Long Run.—A Rambler Model 34-A, driven by "Sandy" Dunlop, of Salt Lake City, arrived in Chicago last week, having made the 2,018-mile trip over the difficult roads in ten days without any serious trouble. The car is owned by J. A. Pollack, of Salt Lake City, and they are now on the return trip, going by way of St. Louis and the Southern route. On the trip eastward they averaged better than 190 miles a day, which is rather exceptional, especially through Wyoming, where the roads were in bad shape from the recent rains.

A New "Show Me" Country.—According to Sales Manager Churchill of the Winton Company, the original "show me" country is on the Pacific Coast, and not Missouri, at least as far as the automobile trade is concerned. Mr. Churchill is now on his annual trip to the Coast, and finds trade there large and growing fast; that the Winton Sixes have taken to the hard work along the coast in fine shape and feels perfectly satisfied that his company is getting its full share of Western buyers.

New Licenses in Ohio.—The new automobile license law of Ohio has now been in effect for over three months and Registrar F. H. Caley reports that he has collected $51,470.10, of which $33,470.10 goes to the State for general revenue fund and $18,000 is retained to pay the expenses of the administration until January. Licenses have been furnished to 9,639 owners, 1,549 chauffeurs, and 146 manufacturers and dealers. This seems to indicate that over 8,200 owners drive their own machines.

New Facilities for the Speedwell Company.—The shipping department of the Speedwell Motor Car Company has always had trouble because of the lack of railroad conveniences near the factory, but this is now being remedied by a spur track which is under construction from the New York Central tracks. Along with the other many improvements which the company is making they will soon have one of the best equipped factories in Dayton.

Loziers Used "Hess-Brights."—It is worthy of note that not only did both the Loziers, in the September meeting at Brighton, use Hess-Bright ball bearings throughout, from crankshaft and camshaft to gearbox and both axles, but out of the five cars making the best mileage four were on "Hess-Brights."

Chief Croker Orders an Acme.—Coridon & Flinn, the New York City agents for the Acme, report that Fire Chief Croker has put in his order for an Acme Sextuplet. Chief Croker has found that it has been a great help in his work to have a machine that could answer fire alarms without delay.

New Ford Plant?—It is currently reported in Philadelphia that the Ford Motor Company has bought a 400-acre tract of farm land and meadow at Cold Spring (near Cape May), N. J., upon which it will build large factories and a speedway for testing purposes.

Harris Oil at Brighton.—The winning Simplex used Harris oil in the recent 24-hour race at Brighton Beach. The problem of lubrication is an important one at any time, but doubly so for any car engaged in a speed contest.

IN AND ABOUT THE AGENCIES.

Ajax Tires, Philadelphia.—Taking advantage of its ideal location for viewing the Founders' Week parades, Manager "Joe" Keir, of the Philadelphia branch of the Ajax-Grieb Rubber Company, at 316 North Broad street, has erected a grandstand in front of the store, and has issued complimentary tickets therefor to all users of Ajax tires in Philadelphia. As this is the branch house's opening week, this novel idea of showing courtesies to visitors is a peculiarly happy one, especially in view of the fact that grandstand seats are being quoted at almost prohibitive prices.

Pierce Arrow, Philadelphia.—The new home of the Pierce Great Arrows in Philadelphia, provided by the Foss-Hughes Motor Car Co. at the corner of Broad and Race streets, has just been opened up with everything ready for the proper handling

New Store of Foss-Hughes Motor Company, Philadelphia.

of the 1909 trade. On the first floor ample show room has been provided with the offices of the company on the second floor.

Kissel Kar, New York.—The Apthorp Motor Car Company, of which F. S. Dickinson is the president and treasurer, has closed a contract with the Kissel Motor Car Company to handle its product in New York and vicinity. A salesroom, opened at 2230 Broadway, will be connected with the garage around the corner on West Eightieth street.

Kissel Kar, Minneapolis.—Among the interesting changes in the Minneapolis trade comes the news that Roy Maxfield has purchased the interests of the Rice Bros. in the firm of Maxfield & Rice, and will continue in the automobile trade at 1401 Hennepin avenue under the name of the Maxfield Company. The Kissel Kar and the Mason lines again will be carried.

Stearns, Pittsburg.—The property formerly owned by the Colonial Automobile Company has been bought by a new concern backed by several of Pittsurg's influential business men, with O. T. Bowman as manager. This company will handle the Stearns car and probably a line of electrics and smaller gasolene machines.

Oakland, Indianapolis.—Preparations are now under way in Indianapolis for an agency which will handle the Oakland cars exclusively. The Independent Automobile Company has been organized and rooms leased at 216 East Vermont street, where a complete line of cars will be on hand.

Stepney Spare Automobile Wheel, New York.—The American Stepney Spare Wheel Company, Eastern distributers, have removed to 1773 Broadway from 341 Fifth avenue, and in new quarters is most comfortably located.

Rambler, Boston.—Manager Charles, of the Thomas B. Jeffery & Co., Boston branch, is preparing to move from the quarters occupied by the Rambler for years on Columbus avenue, to a new and larger store at 95 Massachusetts avenue.

Pennsylvania, Newark, N. J.—The J. M. Quimby Company has just closed a contract with the Pennsylvania Auto-Motor Company, of Bryn Mawr, Pa., to act as distributer of its cars in New York, New Jersey and vicinity.

Rambler, Kansas City.—The Rambler Automobile Company of Kansas City, Mo., has been incorporated and will open up a garage at 1116 East Fifteenth street, in the building formerly occupied by the Midland Company.

Winton, Tacoma.—The Winton Motor Carriage Company has established an agency in Tacoma, Wash., with F. H. Faber, who will open up a model garage and devote his time to the Winton.

Diamond Tires, Detroit.—The Detroit branch of the Diamond Rubber Company will move October 15 to the old quarters of the Cadillac retail department, corner Jefferson and Brush streets.

Oldsmobile, Philadelphia.—The Philadelphia branch of the Olds Motor Works, at 231-233 North Broad street, has been opened, with William T. Taylor as manager.

Gaeth, Pittsburg.—The Arlington Motor Car Company, of Pittsburg, has been appointed agent for the Gaeth car for Western Pennsylvania.

PERSONAL TRADE MENTION.

E. LeRoy Pelletier, advertising manager of the E-M-F Company, will also take care of the advertising for the Studebaker Automobile Company, which it will be remembered purchased one-half of the output of the Detroit concern—6,000 cars—and assumed control of all the Western and Southern territory. This brought the two firms into such close relations that it was thought advisable to have all of the advertising in the hands of one man, so Mr. Pellitier will conduct the campaign for Studebaker commercial wagons, electrics, etc., as well as for the E-M-F.

"Governor" Fred E. Castle has resigned from the position of sales manager for Gray & Davis, and is now considering several promising propositions in which his trade experience of fifteen years, first in the cycling and then in automobiling, may be utilized to the best advantage. Mr. Castle has a wide and valuable acquaintance in all parts of the country, and his friends believe his next business affiliation will be a significant one. For the present he will continue to make his headquarters in Detroit, Mich.

Albert C. Galbraith has accepted a position with the Diamond Rubber Company, and will travel in New England from the Boston branch. He was formerly connected with the Fisk Company in its Pennsylvania, Maryland and Virginia territory.

G. C. Miller, formerly secretary for the superintendent of police of Buffalo, has been appointed sales manager of the Kane Motor Supply Company, of that city, with offices and show rooms at Ellicott and Tupper streets.

Forbes S. Dey, well known to the trade as "Teddy" Dey, and associated with the George N. Pierce Company, of Buffalo, for the past twelve years, has been appointed agent for the Pierce Arrow at Kansas City, Mo.

Charles E. Worrell, formerly with the Waverley branch of the Pope Motor Car Company, has accepted a position with the sales department of the Overland Automobile Company, of Indianapolis.

P. C. Nelson, formerly of the Electric Vehicle Company, has gone with the Newark branch of the Packard Motor Car Company, where he will be connected with the sales department.

James B. Strawbridge was elected general manager and treasurer of the Cleveland Motor Car Company at the recent meeting of the board of directors in New York City.

BOSTON TRADE CHANGES.

BOSTON, Oct. 5.—The first of the month saw a number of notable changes in the local trade. Prominent among them was the removal of the New England branch of Thomas B. Jeffery & Co., from Columbus avenue to No. 93 Massachusetts avenue, the store formerly occupied by Morrison & Price. In his new quarters Manager V. A. Charles has a commodious and well lighted salesroom with ample facilities for storage of parts and making repairs.

The old Rambler store on Columbus avenue has been taken by the Firestone Rubber & Tire Company, which formerly occupied a store in Park Square. Manager T. H. Glenn is making extensive alterations.

The New England Peerless branch has also made a change, but Manager John L. Snow is still satisfied with Columbus avenue as a location. He has taken the store next door to his old salesroom and has made a most attractive salesroom. He also retains a part of the old store for offices, renting the rest to Alonzo G. Peck, the veteran Columbia bicycle agent.

John H. MacAlman, formerly manager of the Columbia branch, now acting as agent for this car, has been deprived of a part of his quarters on Stanhope street, the garage and repair shop having been taken by the electric lighting company, which is fitting up a new garage for its own uses.

On Boylston street the Kissel Kar Company is about opening a store in the quarters formerly occupied by H. C. Stratton & Co.

J. W. Maguire & Co. has doubled the size of its salesrooms by taking down the partition between his old store and that next door, formerly the Napier headquarters.

ROYAL CO. REORGANIZED.

CLEVELAND, Oct. 6.—The Royal Motor Car Company, of this city, has been reorganized after many months of hard work upon the part of a committe of creditors working under the direction of United States Judge Taylor and F. A. Scott, of the Superior Savings & Trust Company, receiver, and in a short time will place upon the market a new model.

The first cars of a new model are now almost completed, and in a short time will be ready for the inspection of the public. The first of the new models to be turned out will be a four-cylinder 55-horsepower touring car, very similar in general appearance to the well-known model G. The Royal people have also been working upon a six-cylinder model of about the same horsepower, and have assembled such a car, it is said, but this model will not be put upon the market this fall.

The generous attitude of the majority of creditors was what made possible this reorganization. The concerns represented by these men have believed ever since the failure that the Royal would pull out of its trouble if given a little aid and help. In support of this attitude, the creditors' committee has been doing yeoman service in an effort to bring something tangible out of the chaos into which the Royal Company was plunged, and the net result is the reorganization.

VETERAN DEALER A BANKRUPT.

Charles A. Duerr & Co., agent in New York for the Royal Tourist and Moon cars, have filed an involuntary petition in bankruptcy, with liabilities of $100,000 and nominal assets of between $65,000 and $75,000. Lindsay Russell has been appointed receiver.

William B. Cooley.

President of the new Waverley Company, and successor to the Popes in the management of the Waverley electrics. The Waverley Company recently purchased the Waverley plant of the Pope Motor Car Company, and Mr. Cooley is one of Indiana's most prominent business men. Associated with him are about a dozen of the best known capitalists and business men of Indianapolis.

INFORMATION FOR AUTO USERS

Break Circuit Auto Lock.—As its name implies, this is a device for locking either an electric or gasoline car, operating directly in the power circuit in the former case and on the ignition in the latter. It is being manufactured and marketed by

BREAK CIRCUIT LOCK FOR GASOLINE CARS.

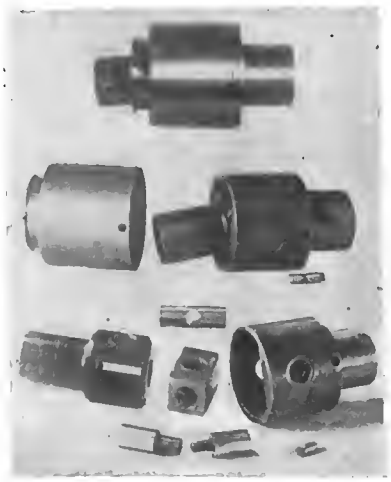
the Safety Device Company, 372 South Illinois street, Indianapolis Ind. When the switch bar of the lock is pulled forward it breaks and locks the circuit automatically, so that no connection can be made until one of the two keys furnished with the Yale lock is inserted and given a half turn, the switch bar then automatically springing back into place. In the case of an electric vehicle, the lock is installed beneath the upholstering on the arm of the seat so that only its face is visible. It takes the place of the ordinary cut-out or plug, and a valuable additional feature is to be found in the fact that on an electric, should it be found impossible to shut off the current to stop the car in any other manner, pulling out the switchbar of the lock will accomplish this.

On a gasoline car it is applicable to any system of ignition, whether with single or double sets of batteries, battery

BREAK CIRCUIT LOCK FOR ELECTRICS.

and magneto, etc., and in the latter case the Break Circuit Auto Lock takes the place of both the switches otherwise necessary. The switch lever of the Auto Lock may be thrown from one set of batteries to the other, or from battery to magneto, but when pulled forward it breaks the circuit completely. The lock is installed on the face of the coil box and once in place there are no exposed binding posts or wires. All necessary fittings and wiring are supplied with the Auto Lock. The latter is furnished in brass or aluminum as desired.

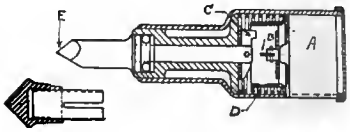
K-B Type "E" Universal Joint.—The Kinsler-Bennett Company, of Hartford, Conn., has designed and are manufacturing a new universal joint to meet the requirements of shaft-driven automobiles of the light and medium type, or for use on motor boats. It is strong and simple, being composed of but few parts. The body is a casing into which is inserted a hardened steel bushing. The sleeve, or yoke, has a rectangular opening which holds the steel block, the joint being held together by a three-quarter-inch steel pin, thus making it sufficiently strong. All working parts have been carefully hardened. To keep the joint free from dirt a steel cover, held in place by a spring plug, slips over the outside,



K-B TYPE E UNIVERSAL, DISASSEMBLED.

and besides this there is a leather boot which fastens to the cover and straps to the propeller shaft. The outside diameter of the joint all assembled is three and a quarter inches. This same concern is also introducing another similar universal for use on low-priced runabouts, known as style D.

New Veeder Speed Indicator.—The Veeder Manufacturing Company, of Hartford, Conn., has just put on the market a new speed indicator which has some new and valuable features. The counter, which occupies the space marked A in the accompany drawing, is the same that has been in use by this company for years, and will operate equally well in either direction. The feature about this new indicator which makes it of especial value is the clutch, shown at B and C, which permits the user when taking the revolutions of a rotating shaft to place the point E in position on the end of the shaft, and with his watch in the other hand, put the counter in operation by pressing in against the spring D at any time he desires. The spring D holds the two parts of the clutch separated unless the pressure of the hand brings them together. This operation is made easy by the ball bearing thrust which has been provided. No matter in which direction the shaft turns, the difference of these two readings will be the r.p.m., if the time has been one minute. The indicator is not effected by a magnetic field; this coupled with the fact



SECTION NEW VEEDER SPEED INDICATOR.

that it works equally well at high or low speeds, makes it adaptable for motor and generator use.

"Trimo" Monkey Wrench.—Under this head the Trimont Manufacturing Company of Roxbury, Mass., one of the oldest and largest manufacturers of wrenches in the United States, has brought out a wrench especially designed to meet the needs of the automobile owner. It is made up of only three parts which are all drop-forgings of special steel and case-hardened. In the accompanying cut the three parts are clearly shown; the handle, the movable jaw, and the nut. The movable jaw is slotted from the head back to the end of the screw so that it slips over the narrow

SIDE VIEW TRIMO MONKEY WRENCH.

portion of the handle and the nut screwed on as shown, with a plug and pin to keep the nut from being screwed back too far while in use. The makers are putting this new design on the market in six different sizes, from six inches up, with larger ones to follow. The same firm have also put out a pipe wrench of a similar design.

Sager Easy Spring.—The J. H. Sager Company, of Rochester, N. Y., the makers of the Sager equalizing spring, has just brought out a new design intended for use on runabouts or any car having stiff semi-elliptic springs. In the accompanying cut the coils spring is shown attached to a

SAGER EASY SPRINGS IN POSITION.

Mitchell runabout, showing how the spring holder is attached to the rigid part of the frame, which the company claims does away with any side motion that tends to take place. On account of the coils being more sensitive than the flat springs the [illegible] of the road are taken by them, [illegible] the resistance of the coils equals [illegible] flat they will work together.

Vol. XIX New York—Thursday, October 15, 1908—Chicago No. 16

THE AUTOMOBILE

Long Island Motor Parkway Has Its Racing Initiation

BY a monster speed carnival, in which all previous American road records were surpassed and stock cars of many makes scored amazing figures in an automobile battle-royal, the Long Island Motor Parkway was inaugurated Saturday, October 10, as a racing course, whereon for all time, without breaking any laws and with safety to contenders and spectators, automobiles may be driven in competition or for pleasure. The assured and partially realized establishment of this great auto speedway and parkway, the results of Saturday's contests, and the possibilities of the course as a trial ground mark the beginning of an era that will mean much to the advancement of the American industry and the popularity of the automobile as a high-speed pleasure vehicle. The successful

Lytle and Winning Isotta Ascending One of the "Hills" of the Parkway Stretch Where the Main Highway Is Crossed.

initiatory of the parkway also gives promise, in the class of the contenders and in the comparative speed results, of a Vanderbilt race on October 24 that will mean no loss of prestige to America's great classic road race.

The outcome proved the practicability of the innovation of combining several contests among variously graded machines at different distances, and also set a fashion that is likely to be frequently followed in future long-distance stock car races on the road. Endurance runs, under varied or average highway conditions as tests of serviceability, and hill climbs, as proof of power under grade emergencies, are convincing to many, but it is doubtful whether the arbitrament of sustained speed over long distance does not appeal most strongly to the majority. This has been European experience. The selling success that has followed notable speed successes in this country would seem to confirm to a considerable extent the European ideas. Hitherto it has been sought to supply the fancied want by track contests, but their practical results have paled by comparison with those of such great road races as the Vanderbilt, the Savannah, the Briarcliff, and the Lowell. The building of the Long Island motorway is a great step toward furnishing this form of test; in fact, the Long Island cement stretch has actually solved the problem of a safe and lawful speed arena.

While interest was naturally greatest among the general public in the contention of the cars of the highest price and power, the struggles of those of lesser value were closely followed by those who looked to the series of sweepstakes to furnish evidence of the relative speed and road qualities of the various models and price classes; in a word, by the members of the automobile cult whose choice and purchase are affected by such car demonstrations. And their friends buy likewise.

The big race of the day, of course, was the Motor Parkway Sweepstakes, whose finish came after the contenders in the other five sweepstakes had run their course, gathered their respective laurels, and earned their thousand dollar prizes. It had added interest from the fact that its list embraced several prominent Vanderbilt Cup cars and drivers. There were Herbert Lytle, a well-known Vanderbilt Pope-Toledo driver and who also successfully piloted an Apperson at Savannah, at the wheel of Clifford V. Brokaw's Isotta; Louis Strang, probably well entitled to be called the American road champion, who has just been retained permanently by Paul LaCroix, in the Renault; Charles Basle in the Knox, which finished second in the Lowell race; F. Lescault with the Simplex that captured the last Brighton Beach 24-hour race, and Willie Haupt and the Chadwick he had driven so successfully in the present season's hill climbs.

Strang's Renault Flying Past Grandstand.

Strang, through his victories with the Isotta in the Savannah, Briarcliff, and Lowell contests, and Robertson, by his win of the Brighton Beach 24-hour race and his more recent triumph at Philadelphia, have earned the premiership among our drivers in critical and public estimation. The outcome of the Motor Parkway Sweepstakes easily places Lytle on a par with these two, and assures America of a trio instead of a duo of drivers in the international races at hand that bid fair to give as good an account of themselves against the foreign cracks as did Joe Tracy with the Locomobile in the last Vanderbilt race.

Under Lytle's brilliant pilotage the Isotta added the Motor Parkway Sweepstakes to its Savannah-Briarcliff-Lowell honors, and, incidentally, annexed a new American long-distance road record as well. It covered the ten laps of the 23.46-mile course, 234.6 miles, in 3 hours 39 minutes 10 seconds. It averaged 64.25 miles an hour, as compared with the best previous American average of 61.43 miles, scored by Wagner when he won the 1906 Vanderbilt Cup race with the Darracq.

Strang made a game chase with the Renault, tying the Isotta the first lap, but from that point on being gradually and very slowly outfooted, finishing 11 minutes 15 seconds behind the Italian car. Strang had made the run in 3 hours 50 minutes 25 seconds and scored an average of 61.20 miles per hour, which was but a shade under Wagner's former record. The Itala was third, the Simplex fourth, and the Chadwick fifth. The Knox and Hotchkiss completed but six and five laps, respectively.

The Meadow Brook Sweepstakes at 211.14 miles, for cars from $3,001 to $4,000, fell to the Allen-Kingston, driven by H. Hughes, a car that has made heretofore most of its reputation in short and long-distance track events. It made the run averaging 52.6 miles per hour. Mrs. Joan Newton Cuneo's Rainier, of Glidden tour fame, piloted by L. A. Dis-

brow, ran a creditable second at an average of 52.2 miles per hour. The Lancia, driven by W. M. Hilliard, third, averaged 47.9 miles. This car possessed the smallest cylinders, 3 1-2 bore by 3 7-8 stroke, of any car in the race, except the Nassau little fellows. It made the 211.14-mile run on 13 gallons of gasoline, an excellent showing.

Another newcomer to the metropolis, a Sharp-Arrow, so new and so insignificant from the point of production, being the creation of a Trenton, N. J., enthusiast, as to be looked upon as a free lance. W. H. Sharp, who drove it, walked away with the Garden City Sweepstakes at 187.68 miles, with an average of 56.4 miles an hour. As a matter of fact, this average was beaten by only two cars in the entire sweepstakes, the Isotta and the Renault. The Sharp-Arrow is an assembled car with a Continental engine. There was talk after the race of a protest of the car on the ground that there had not been a sufficient product to comply with the stock car rules requirements. It was claimed at its supply pit, however, that 40 of the cars had been produced. William Bourque's Knox, which is entered for the Vanderbilt Cup, finished second, with an average of 45.2 miles an hour.

Chalmers-Detroit Overhauling Buick.

The two Chalmers-Detroit candidates for the Jericho Sweepstakes, for cars from $1,001 to $2,000, made a most successful and impressive racing debut. They ran first and second, and were driven, respectively, by W. H. Burns and J. D. Ainslie. The winner covered the 140.76 miles at an average of 48.65 miles per hour. The average of the second to finish was 46.1. Their nearest pursuers were a pair of Mitchells.

Among the little fellows in the Nassau Sweepstakes, for cars of $1,000 and under, the Buick had it pretty much all its own way, making the 93.84 miles run with an average of 44.1 miles per hour.

The contest of the tires was also closely watched. It was Michelin's day, for Michelins were on the Isotta and Renault, the first and second in the big race, and on the winning Allen-Kingston, Sharp-Arrow, and Buick. Diamonds scored first and second in the Jericho with the Chalmers-Detroit pair.

The race was remarkably free from accidents of all kinds, either to men or machines, considering the large number of starters. In fact, but one participant was injured. In rounding a curve a Stoddard-Dayton, driven by A. C. Miller, threw off its mechanic, William La Motte, breaking his arm. Another Stoddard-Dayton, with K. Wright at the wheel, was ditched and put out of the race in the first lap. A Palmer & Singer, piloted by Ray Howard, was put out of the race by running into a fence, but neither of its crew was injured. The Chalmers-Detroit "40," which L. B. Lorimer drove, ran into a dog and broke its radiator. The latter leaked so badly that the car discontinued the contest. Two instances were reported of spectators being hit by flying pieces of metal or wood as the cars rounded the turns.

The management of the race by the A. A. A. and Motor Parkway officials was excellent, William K. Vanderbilt, Jr., acting as referee. The protection of the spectators was efficient. There was a large corps of Pinkerton men along the homestretch in the neighborhood of the grandstand. At other points of the route were stationed deputies, a large number in the aggregate. The Parkway cement stretch was well protected by a high wire fence, though this stretch runs for most of the way through the barren Hempstead plain and really was too isolated to be in danger of congested crowds, anyhow. Flagmen encorded the entire course to signal the drivers.

At the start and finish the Motor Parkway Company had erected a monster permanent stand seating 5,000 people and opposite thereto a two-story structure for officials and newspaper men. At the front of the grandstand were several rows of commodious boxes, behind which seats rose in tiers to the great roof, in itself an innovation for racing stands. The front of the stand and boxes was hung with purple cloth; festoons of the shields and flags of all automobile racing nations surmounted the pillars; and above the roof floated great American flags.

The official and press stand was most complete in its equipment. Above were score boards for each sweepstakes. The main floor was given over to long tables for the newspaper men. Behind them were booths for the telegraph operators and 15 telephones. The officials had a compartment to themselves at the tape end, and in the corner was a most hospitable bar. In the second story were Charles J. Dieges and S. M. Butler and other members of the New York Timers' Club, who looked after the clocking; the scorers' tables, and more benches and desks for newspaper men. There was an abundance of room for pressmen.

The most novel and interesting part of the homestretch equip-

Behind the Parkway Bars

ment, however, was the row of supply pits that stretched in front of the grandstand for its entire length. There was space enough between the pits and the track for racing cars to stop for their supplies. Mountains of tires were dumped into the pits in the aggregate, to say nothing of the rivers of gasoline and oil. It was highly interesting to watch the crews take on their supplies and make their adjustments. There were at times repairs made that were of hitherto unaccustomed frankness. It is safe to say, however, that when possible the more serious work was reserved for the other official supply station on the backstretch. So far as the grandstand pits showed, however, there seemed remarkably little repairing and adjusting to be done.

There Was Not Much Tire Trouble.

In front of the grandstand stretched the long broad ribbon of white cement, plain to the view for a mile in either direction. To the west it approached over a hill that bridged an intersecting highway and disappeared to the east beneath a bridge that furnished a crossing for another road. The surface of the cement was roughened to prevent skidding, and at the turns the path was well banked. There had been fears that the rough surface would prove hard on tires. This turned out not to be so. On the contrary, there was less tire trouble reported than at any former road race. In fact, Peter Prunty's once familiar announcement, "Stopped by tire troubles," was heard only occasionally.

So smoothly and swiftly did the racing cars speed over the level surface of the parkway stretch that some pilots were forced into the belief that their machines were not making as rapid progress as they did over the smooth country roads that made up two-thirds of the circuit. In fact, "Herb" Lytle stoutly maintained that the Isotta traveled ten miles an hour faster over the backstretch than it did over the parkway. The truth is the monotony of speeding over a uniform surface and the absence of any resistance or necessity for swerving to pick a path deceived the pilots. One has heard the novice drivers over Ormond Beach complain that they were disappointed in the speed the beach gave. The watch soon undeceived them, just as it undoubtedly would were the time taken over the parkway stretch. It would, by the way, be most interesting at the Vanderbilt Cup race could there be devised some way of getting and announcing the times the cars made from the beginning to the end of the parkway stretch, or from its start to the grandstand.

The start for the race from town began before daylight for the general public. The Long Island Railroad had arranged for a big and frequent train service. The first was advertised to leave at 5 o'clock. It was fully half an hour late in starting and was made up of seven cars only fairly well filled. The early racegoers were dumped out on a siding behind the stand with a quarter of a mile walk across the meadows ahead of them. When they reached the stand only A. R. Pardington and a few employees and Pinkertons were on the ground. Soon, however, automobiles began to arrive, coming down the course from the toll gates, and took their stations on the broad borders on either side of the path. The distant bridge soon filled with cars, whose owners had framed up this fine viewpoint. Before the race began there were perhaps a hundred cars between the grandstand and the bridge. The grandstand was slow in filling. To tell the truth, it did not nearly fill. There were spectators in perhaps half the boxes and a thousand or so in the seats. The crowd was swallowed up by the monster stand. Along the country highway section of the course there were thousands of people and hundreds of cars in the aggregate. That the grandstand was isolated in an unknown district, that big fees were charged for seats and parking spaces, that the viewpoints elsewhere on the course were free, and that the sweepstakes being merely a curtain raiser to the near-at-hand Vanderbilt race suffered by comparison so greatly as to injure the attendance, were among the guesses given for the patronage of the center point of the struggle being so unexpectedly small. Some thought that the splitting of the race into sub-divisions, while novel and interesting from a trade standpoint, lacked the concentrated attraction of a single contest, from which a single individual winner was to be evolved.

Parkway Curves Are so Scientifically Constructed that the Cars Had no Difficulty Whatever in Sustaining the Highest Speed.

At 8 o'clock, an hour before the time set for the start, Fred J. Wagner, the official starter, arrived and set to work to get the racers into line. It was an easy task for this experienced hustler to line them up in a double row, with even numbers on one side and the odd on the other, the various classes or sweepstakes following one another in the order set for their start.

Just before this Referee Vanderbilt had driven up in a big touring car with three friends. He wore a long overcoat instead of the usual natty "knickers" and Norfolk jacket. It was an overcoated and fur-wrapped crowd. A chilling wind blew stiffly from the north and officials and spectators promenaded briskly to keep warm. The shivering newspaper men found writing hard with benumbed fingers. The drivers had a cold ride ahead of them.

Many Prominent in Sport and Industry.

In the throng along the homestretch were many men prominent in the sport and industry. With so many makes of cars represented, their backers alone made quite a noteworthy array of trade leaders. There were conspicuous evidences of a truce in the racing war, if not an end to it altogether. A. A. A. and A. C. A. officials were both on hand and commingling in apparent fraternity. The rival chairmen, Thompson and Morrell, chatted cordially together, and Secretary Butler busied himself with preparations for the timing and scoring with as much hustle as though the scene was Savannah and the Grand Prize was about to be started.

Sharp at 9 o'clock "Wag," with Charley Dieges and "Sam" Butler at his side, the former holding a big ship chronometer and the latter with notebook in hand, sent away the first of the little fellows, a Mitchell, a candidate for the Nassau "thousand." The other Nassauvians were started at half minute intervals. The first of the Jericho outfit was started at 9:05, the Garden City at 9:10, the Meadow Brook at 9:15, and the Parkway at 9:20, the cars in each leaving at the same half minute intervals. But four of the 37 entrants failed to face the starter. They were the Garford, Pennsylvania, Cleveland, and Moon cars.

And When the Races Were On.

The first car to complete a lap was the Buick. It had gotten by the Gyroscope and Mitchell, and made the 23.46-mile round in 30:55. A string of cars followed at short intervals and so fast that the announcer and the tally sheet-keepers in the press box were soon lost in the shuffle. There was confusion for a few minutes, and then "Hank" Caldwell, A. B. Tucker, and others came to the rescue with score slips which they read aloud. Even after that it meant lively hustling for the scribes to keep tally of the race, so fast and frequent was the passing of the cars. Even in the first two laps cars overtook and passed cars of the sweepstakes starting ahead of them. The best battles of all the classes were those of the little fellows in the Nassau and the big 'uns in the Parkway.

In the early stages of the race the duel between the Isotta and the Renault was intensely exciting. Lytle and Strang were tied to a second the first round, but the next lap the former Pope pilot gained some three minutes on the three-cup winner, Strang. The Italian car, as a matter of fact, pulled away from the French machine at an average rate of a minute a lap, though Strang reduced Lytle's lead to four minutes in the seventh round. The Knox gave Lytle and Strang a close run for the leadership in the first round, but after that dropped back into the ruck. The Itala got into third place in the fourth round and was never dislodged therefrom to the finish. The Hotchkiss was never dangerous after the third lap. The Chadwick put up a good fight for third place for six rounds, but after that was passed by the Simplex.

Though the Allen-Kingston led all the way in the Meadow Brook, the Rainier, a newcomer in the racing field, gave it a pretty good rub from start to finish, being beaten out by less than three minutes. The little Lancia did wonderfully fast work, considering its small cylinders. Hilliard negotiated laps in the "28's" practically the entire way, but this was not quite fast enough to win in company so much higher powered.

The Sharp-Arrow had things practically all its own [illegible] two laps in the Garden City, and well it might, for it proved itself second in speed only to the Isotta and Renault. Its runaway, however, did not come until the third lap, for Burman (Buick), Lorimer (Chalmers-Detroit), and Howard (Palmer & Singer) all led it to the first lap. In fact, Howard led his field for two laps until the Palmer & Singer met with its accident and had to quit, its time having been 23:42 for the first and 46:29 for the second lap, as against 24:48 and 49:19 for the Sharp-Arrow. Much had been expected of the P. & S. car, and its disappearance was a source of disappointment to many. The Chalmers-Detroit pair had the Jericho practically all to themselves, the only car to dispute their leadership and continue the race to the end being a Mitchell, driven by Frank Zirbies.

The Nassau was the merriest of merry scrambles, from which Hugh Easter and his Buick emerged a leader at every lap of the biggest field of the whole race, thus atoning largely for the disappointment Mr. Durant had experienced in Robert Burman's failure to win the Garden City.

This Part of the Parkway Resembles a Huge Circular Track, but the Curve Is so Gradual that Top Notch Speed Was Possible.

TECHNICAL SIDE OF THE FIRST TRYOUT OF 1909 CARS

By CHARLES B. HAYWARD.

ALTHOUGH it was scheduled as a race, and presented to the public as an event of this character, last Saturday's canter round the Long Island course, preliminary to the holding of the Vanderbilt Cup race on the 24th, was in reality a competitive tryout of new models where a number of the entrants were concerned—the first on the slate for the new cars of next season, as well as the first of its kind ever held in this country. American manufacturers maintain a high standard where what is known as the "trying-out" process is concerned, and, before receiving the final seal of approval, a model is usually run a year or more on experimental work, while each replica of the standard thus evolved is given a thorough running-in by the factory tester before it goes to the body shop and thence to its new owner.

But what makers have been hankering after has been an opportunity of trying-out their new productions each year in competition with the cars of other makers. This, the Swecpstakes events, held on the Long Island Motor Parkway and adjacent roads last Saturday, provided in hitherto unprecedented manner. True, there were some that were not new models, mostly in the foreign entries, but the majority came under this head, and the performance of the various entrants gave prospective purchasers an excellent opportunity of judging of the merits of the new productions of quite a number of makers.

It was essentially a battle of four-cylinder cars, as with the single exception of the Chadwick, piloted by Willie Haupt, who fought for top-line honors in the Motor Parkway sweepstakes, there was not another six-cylinder car to score, and, as a matter of fact, but one other was entered. At the other end of the line,

in the Nassau sweepstakes class, there were a couple of exceptions to the four-cylinder rule in the shape of the twin-cylinder Reo and the lone representative of the one-lunger class, the little Cadillac. Otherwise, it was largely a case of piston displacement on the basis of four cylinders, as apart from the higher-powered cars in the star event of the day, which were almost equally divided between chain and shaft-driven types, the great majority of the entrants formed a more or less close approach to a standard of construction in the shape of a shaft-driven car that is now very general.

If the results of a race could be predicated solely upon the efficiency of the motor and the various essentials of its transmission in delivering the power to the driving wheels as a basis, it would be easy to mechanically classify the contenders according to their order of finishing, barring mishaps that could not well be taken into account in such a summing up. But it has been shown time and again that not only generalship in driving, but also that final tuning up, which can only be done properly by the skilled hand, is of paramount importance, while the element of luck holds every driver's destiny more or less in hand from start to finish, so that the best efforts of the designer and maker are not always rewarded to the fullest extent.

Isotta.—This car has been a top-liner so often during the racing season of the present year that its principal features have become very well known, as the contender on the Parkway last Saturday was a duplicate of the machine that Strang has piloted to victory on three other occasions this year. It is nominally rated at 60-horsepower, but is naturally capable of an output considerably in excess of this, particularly as its motor can be run at a very high speed without a falling off in its power, owing to the unusually large size of its valves.

Stoddard-Dayton in the Grandstand Stretch.

Sharp-Arrow.—Except insofar as its mechanical details could be judged from an exterior view, this car was as much the dark horse of its class technically considered as it was from every other point of view, as it was an eleventh-hour entrant about which little was known at first and its successful performance only served to deepen the mystery. It came out later that it was equipped with a Continental motor, and in all probability its other essentials came from equally well-known parts makers, so that as an assumption of what its mechanical details may be, a four-cylinder motor of 40-50 horsepower, some standard type of clutch, a four-speed selectively operated gear-set with final drive by shaft, many of these details naturally being self-evident, will doubtless not be far wrong. Its designer was at the wheel.

Allen-Kingston.—The "A-K" is a car that has given evidences of its capacity for speed and endurance on racing occasions during the past year. It has a four-cylinder motor measuring 5 by 5 3-4 inches and is rated at 40-45 horsepower, a Bosch high-tension magneto supplying the ignition, while a pump and circulating system takes care of the oiling, and a Breese carbureter completes the essential accessories.

Chalmers-Detroit.—Owing to the numerous features in which this little 24-horsepower car differed from its competitors in its class, its performance was looked forward to with a great deal of interest and much was expected of it. Its four-cylinder motor is cast *en bloc* with both the intake and exhaust passages integral, while the circulation of the cooling water is on the thermo-syphon principle. Dual ignition is provided, consisting of a Bosch high-tension magneto and a standard set of unit coils and timer fed by a storage battery. The clutch is of the multiple-disc type and the sliding gear-set, acting selectively, provides three forward speeds, the motor, clutch and gear-set all being combined so as to form an extremely compact and light power-plant. Lubrication is effected by means of an extremely simple and reliable circulating system employing a gear-driven pump, while the carbureter is the same type as is used on the Chalmers-Detroit Forty.

Buick.—This little 18-horsepower car proved considerable of a surprise to those who were trying to figure the chances of the entrants in the small car class, particularly as the use of a two-speed planetary gear is not considered the best possible equipment for racing purposes. This car's four-cylinder motor measures 3 3-4 inches "square," while its most important accessories consist of a Bosch high-tension magneto, a Hill Precision lubricator, and a Kingston carbureter.

Some Creditable "Also Ran" Performances.

While the puhlic usually concerns itself with the winners alone, the observer who keeps his eyes open during the course of a race, and particularly at the finish, can often find more cause for congratulation in the performance of the cars that missed getting all the glory in their classes than those that shone forth most brightly in the lime-light of the tape. In the first two classes, the Renault and the Knox stand out strongly, while in the Meadowbrook sweepstakes, the work of the small Lancia was positively eye-opening.

For instance, the Renault was the standard 35-45 horsepower put out by this firm and the fact that its average for the distance was but three miles less than its much higher-powered rival hardly calls for any comment. In the case of the Knox, it was more difficult to judge of what Bourque had to run against as no one solved the mystery of the Sharp-Arrow.

Doubtless the most phenomenal performance put up by any of the cars, considering its horsepower ahility as compared with others in its class, was that of the Lancia, which with its 3.5 by 3.9-inch eylinders was pitted against cars nominally rated at 50 horsepower and concededly capable of a great deal better, so that its average of hetter than 47 miles an hour for the entire distance is not alone remarkable, but shows what a very close approach it made to the performance of cars of double its size. The absolute uniformity with which the laps were reeled off is also noteworthy, as its time differed but a few minutes at the most, and was frequently only seconds apart for the various laps.

RACE GOSSIP GATHERED FROM VARIOUS SOURCES

Auto Notables on Hand.—Noteworthy among the trade leaders at the trackside were: H. B. Joy and M. J. Budlong, of the Packard Motor Car Company; E. T. Birdsall, of the Selden Motor Vehicle Company; C. H. Tangeman and Harry Fosdick, of the Hol-Tan Company; C. A. Singer, of the Palmer & Singer Manufacturing Company; R. M. Owen, sales agent for the Reo and Premier; C. M. Hamilton, of the Isotta Import Company; Paul LaCroix, of the Renault American agency; John Matlack, of the Michelin Tire Company; W. M. Lewis and C. P. Skinner, of the Mitchell Motor Car Company; Alfred Reeves, of the American Motor Car Manufacturers' Association; A. R. Whitney and Ralph Newton, of the Stoddard-Dayton agency; Carl H. Page, of the Chalmers-Detroit and Peerless agencies; Hugh Chalmers, R. D. Chapin, and H. E. Coffin, of the Chalmers-Detroit Motor Company; W. E. Metzger, of the Everitt-Metzger-Flanders Company; E. Lillie, of the Itala Import Company; E. H. Broadwell, of the Fisk Rubber Company; John T. Rainier, of the Rainier Motor Car Company; C. G. Stoddard, of the Dayton Motor Car Company; S. A. Miles, of the N. A. A. M.; E. P. Chalfant and C. F. Clarkson, of the A. L. A. M.; W. F. Wright and C. R. Culver, of the Knox Automobile Company; A. G. Southworth, of the Buick agency; Herbert Githens, of the G. & J. Tire Company, and Charles Meyers, of the Diamond Rubber Company; L. R. Speare, S. L. Haynes, J. P. Coghlin, W. H. Chase, Paul Wolff, Secretary F. H. Elliott, and other A. A. A. directors.

Converted to Racing.—Hugh Chalmers, Roy D. Chapin, and Percy Owen were conspicuous at the Chalmers-Detroit pit. The rôle of backers of the racing game was a bit new to Messrs. Chalmers and Chapin, though Mr. Owen is a veteran of the early days and a former Gordon-Bennett pilot. The double success of the Chalmers-Detroit on its debut in speed competition also made enthusiastic converts of the Detroit members of the trio. In future they may be found flying higher.

Want a Night of It.—One of the reasons advanced for the small attendance of the general public at the race, as compared with that of previous Nassau County contests, was that being started at 9 o'clock it did not appeal to the sporty crowd, which liked an excuse to make a night of it, nor to those seeking the novel adventure of midnight race going. It was argued that thousands of people would travel by night to see a race that started at daylight, who would not get up at daylight to get to a race that started at 9 o'clock.

"Darn That Band."—Music had no charms for the scribes who were striving to catch the times from Peter Prunty's megaphone and "Hank" Caldwell's mouth organ. The newspaper fraternity is unanimous in its demand that the band be moved across the course to the grandstand from its present location alongside the press box. They say, by the way, that by Vanderbilt race time there will be score boards in front of the press stand to stop newspaperdom's frantic howls for "Time."

Physicians on Hand.—Dr. Louis N. Lanehart, of the Nassau Hospital, was at the grandstand with a corps of surgeons and trained nurses prepared for any emergency. A White steam ambulance was also in readiness for a quick run to the hospital at Mineola, should there be an accident.

To the Vanderbilt by Electricity.—By the time of the Vanderbilt race the Long Island Railroad will have completed its line of electric poles to the siding at the rear of the grandstand. This electrification of the service will vastly quicken it.

Evidence of Peace.—Former A. C. A. Presidents Colgate Hoyt, and Winthrop E. Scarritt, Chairman Robert Lee Morrell, and Secretary S. M. Butler were in evidence at the starting point. Mr. Butler superintended the timing and scoring.

"Suppose It Rains?"—"Suppose it should rain on Vanderbilt Cup day what would happen those poor devils in the supply pits?" asked one of the inveterate trouble-seekers.

A Smooth-Faced Referee.—The photographers had an excuse to snap the much-pictured referee repeatedly, for since the last race Mr. Vanderbilt has shaved his mustache.

Garden City Hotel Crowded.—Though there was not the hurrah at the Garden City Hotel that is incident to the night before a Vanderbilt race, there was enough of a crowd on hand to force the management to put several beds in rooms.

Little Fellows Slowed Big 'Uns.—The drivers of the big cars all agree that the obstruction of the small cars on the course made a big difference in the time, owing to their slowing down constantly through fear of collision. Lytle is sure that the Vanderbilt will show at least five miles an hour better.

Fosdick Averts Danger.—Some one undertook to water the stretch in front of the supply pits, several mechanics having complained of the dust. Harry Fosdick, however, protested, since the mixture of oil drippings and water endangered some car skidding into the pits. A spectator's clothes, by the way, were ruined through a wheel spinning and throwing the greasy muck on him.

Chadwick, Haupt Driving, Ascending the "Hill."

Congressman Chases Fakirs.—One of the biggest outlying crowds was gathered at the junction of the Jericho turnpike and the old Westbury road. Some light-fingered gentry set up some roulette wheels there. It happens that the crossroads at this point adjoins the estate owned by Congressman William W. Cocks, of automobile law fame. Mr. Cocks landed suddenly on the scene and without ado kicked over the table and put the gamblers to flight. One of them attempted to again set up his wheel in an adjoining field. By this time the congressman had his fighting blood up and the rural croupier did not dare even to look back until he had put a mile of road behind him. Some three-card monte men, by the way, tried to work the first race train out of Long Island City, but they found the early bird mechanics and newspaper men too "wise guys" to fall for their game and they only got the laugh along the aisles of the cars when they tried to catch a victim.

Sharp-Arrow, One of the Parkway Surprises.

Railbirds on Bridge Enjoying the Racing.

The Air-cooled Cameron Starting on Its Journey.

Here's Where the Parkway Passes Under the Main Road.

Quakertown's 200 Mile Captured by a Locomobile - Robertson driving

PHILADELPHIA, Oct. 10.—Amid the plaudits of as many of the more than four hundred thousand spectators as could get within eyeshot of the finish, George Robertson to-day drove his Locomobile "40" across the line a winner of first honors in the Founders' Week 200-mile stock chassis road race. Cyrus Patchke with a 45-50 Acme finished second, over twelve minutes behind. Ralph Mulford, 50-horsepower Lozier, was third, and Bert Maucher, a local driver, came in fourth with his 38-horsepower Peerless. The course was 7.8 miles long, and 25 circuits were made—195 miles.

The sixteen contestants were all lined up awaiting the road for fully a half-hour, and the first car was started just as the factory whistles in the nearby city sounded the signal for beginning the new day's toil at 7 o'clock. They were sent on their 195-mile journey at half-minute intervals in the following order:

Car.	Cyls.	H.P.	Driver.	Tires.
1. Maxwell	4	28	H. Bittner	Ajax
2. Apperson Jack Rabbit	4	48.4	George Davis	Diamond
3. Peerless	4	38	Bert Maucher	Diamond
4. Pullman	4	40	Max La Roche	Diamond
5. Thomas*	6	70	George Salzman	.....
6. Studebsker	4	38.5	Frank Yerger	Diamond
7. Chadwick	6	50	Jack Harkins	Diamond
8. Stoddard-Dayton	4	34.5	E. C. Ireland	Contin'ti
9. Locomobile	4	40	J. W. Florida	Firestone
10. Locomobile	4	40	George Robertson	Firestone
11. American Locomotive	6	60.	L. J. Bergdoll	Fisk
12. Palmer & Singer	6	60	Wm. Wallace	Contin'ti
14. Acme	6	45-50	Cyrus Patchke	Diamond
15. Lozier	4	45	H. Michener	Contin'ti
16. Pennsylvania	4	38	Len Zengle	Diamond
17. Lozier	6	50	Ralph Mulford	Contin'ti

*Substituted for Welch 6-51, withdrawn.

The race was hard-fought from the start to near the finish. Just how close it was can be gathered from the fact that at the beginning of the 20th lap—148.2 miles—seven of the nine cars still in the race were separated by less than a lap. At that point Robertson's time on the leading Locomobile was 3:05.14. "Bill" Wallace, in the 60-horsepower Palmer & Singer, who occupied seventh position, was a little over eight minutes behind the Locomobile, for when he flashed past the tape the clocks registered 3:13:41. Just at this point a smash-up or persistent tire trouble could have sent any one of the others into the lead, but Robertson played safe, and by continuing to grind out 9:30 laps, according to the schedule, he finally wore down his opponents. Five cars covered the entire distance, although Florida's Locomobile was shut off from an official finish by the crowd. Frank Yerger's Studebaker was also running, five laps behind.

Robertson, who has many victories to his credit, can hardly appreciate any of them as highly as he did that of to-day. Not only was his win witnessed by a record-breaking crowd, but unless he has a particularly level head it was at least temporarily turned by the adulation of the hero-worshiping Quakers. Mayor Reyburn, who handed out the plunder after the race, metaphorically patted him on the back to the limit; Mrs. Reyburn insisted on poor, blushing "Robby" taking a bunch of American beauties, and when the crowd yelled "Speech!" the winner looked helplessly about, almost dropping the huge $2,000 Founders' Week cup that he hugged in his arms, and begged Glenn Ethridge, his mechanician, to "crank 'er up and let's get out of this." But the crowd was so dense that the winning Loco simply couldn't get through, and its team had to go through a course of hand-shaking such as would have made a presidential candidate's arm sore for a week.

It was a great day for Robertson and Ethridge and the Locomobile, not to mention the Firestone tires, which had carried the combination to a well-earned victory. The Acme, which finished second, was fitted with Diamond tires, as was the Peerless, which came in third. The Mulford Lozier, which finished in fourth place, carried Continental tires.

The fastest bit of work in the race was seen during the Lozier 50's tenth lap, when Mulford, in an effort to get up—he was five minutes behind the leader at the time—sent his car around the circuit in 8:32, creating a new record.

While the victory is the Locomobile's, it might not have been possible without Robertson. Over such a course, with no long straights, heady driving counts more than in a long circuit, with five and ten-mile straightways. On a long course the car's speed has a more direct relation to the result; on the Fairmount Park circuit intelligent driving is more than half the battle. There were speedier cars in the race than the Locomobile, but there were no headier drivers than Robertson. He nursed his tires on the turns; he took no chances on "grandstand" work. Those who, perhaps, were disappointed at his victory, said "Luck!". He made but one stop, it is true, but that was because he treated his car and his tires as tenderly as the conditions of a bruising race would permit. When, at the conclusion of the 15th lap, he considered it advisable to replenish his fuel, he passed the word to be ready with a complete set of tires when he came around on the next lap. All hands were ready, and the car had hardly come to a standstill before the Loco helpers were all over it like a colony of ants. In less than three minutes he was off. Organization helps.

Patchke, in the Acme 40-45, was compelled to make four stops —three for tire trouble (all on the road, away from the control) and one for fuel. These it was that helped keep him back. His car was fully as fast as the Loco, but his tire troubles, occurring, as they did, at points far removed from the Acme control, put all the work on him and his mechanician, Jere Price. Not a few valuable minutes were lost to the Acme-Patchke combination in consequence.

When interviewed after the race, Robertson was quite modest over his victory and was as ready to ascribe his success to good luck as were some of the disappointed ones. "We hadn't the semblance of an accident," he said, "and my car ran just like a well-taken-care-of watch. We stopped but once, and did everything needed to the car then, including the putting on a full set of Firestones. The tires we started with were not bad, but we had a little in bank, and played things safe. The course was not a fast one, and I early realized that any one who attempted to 'beat it' would come to grief. I figured it out that the Loco outfit could stand a 50-mile gait and win. I adhered to that schedule as nearly as I could."

Patchke, whose Acme finished second and won the MacDonald & Campbell cup, and who also captured a diamond ring for himself, said: "We lost our chance when our tires began to give way, as luck would have it, as far as possible from our control. Price and I had to 'get on the job' three times, and once you fall behind on that course, there is little chance of getting to the front, unless the leaders 'get theirs'. They didn't, and there you are." Asked to explain, he corroborated Robertson's statement that a speed in excess of 50 miles an hour meant trouble. The only stretch where sustained speed was possible, along the West River drive, was somewhat soft, the oil with which it had been liberally treated having filtered through the loose top dressing and leaving the surface mushy.

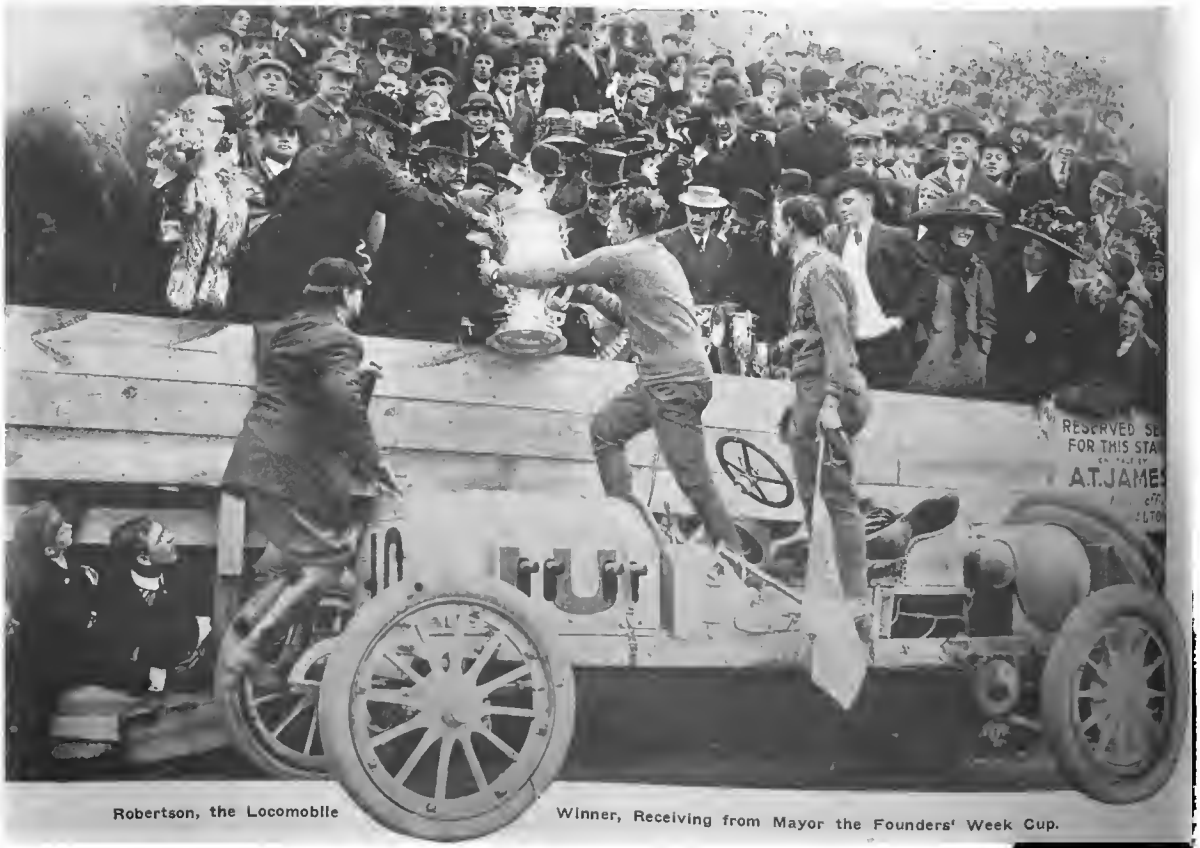
Ralph Mulford, driver of the Lozier "six," while somewhat disappointed over the result, said he might have won had the race been twice as long. "We were on the same lap with the leaders right up to the 20th round, when we lost six minutes with a bad tire. We showed what we could do on the tenth lap, when we made the fastest circuit of the day." And he showed the *North American* trophy which he had captured as the result of that fast bit of work.

Salzman won the *Record* cup for making the fastest time in the first lap with the Thomas—8:57. The *Press* trophy for the best average time and the *Evening Telegraph* cup for the most uniform time for the 25 laps have not yet been awarded.

It was a bleak morning, with a strong northeast wind chilling the marrow of the thousands of sport-loving Quakers who had left their warm couches to witness the novelty of a big road race right at their doors, as it were. All the trolley cars were put at work an hour earlier than usual to accommodate the huge crowds who flocked to the park. Many automobile parties went out to the course shortly after midnight in order to secure favorable positions to witness the race; not a few of them provided themselves with the materials for making coffee, and as dawn broke the scene suggested an immense army just waking to the day's activities—lacking the canvas and the instruments of warfare, of course. At the big camp on Belmont avenue, the handlers of the various cars and the tire men were up betimes, several of the racers taking slow trips over the course to finally size it up before the actual race should be on.

The spectators were gratified at the early announcement that the Thomas would start. The A. A. A. officials had limited the number of entries to sixteen, and there were several disappointed candidates when the limit was reached. Erwin R. Bergdoll, however, withdrew his Welch, and as the Thomas was first substitute, it was given the coveted place. It looked like a winner for six laps and then went to the discard with a broken crankshaft.

The management of the whole affair from the beginning was excellent. The mayor was in his place in the official grandstand for five long hours, and under his eye Superintendent of Police Taylor had his men on their mettle. Only one criticism was heard, and that was as to the rather primitive score-board provided. This was built over the press stand, and apparently for the sole benefit of the grandstand occupants. If the press men wanted to see it, they were compelled to descend to the ground and walk out in front of the press stand, jostled meanwhile by the horde of "officials" who seem to do everything but officiate. The score board had but two lines on it—one for laps, the other for time. Whoever built it evidently thought a baseball battle was to be fought out. As each lap was finished, the assistant scorers would sponge out the official time of the car for the previous lap and chalk in the new time. Woe betide the pressman who failed to be on the job when the times were announced! If he wanted to get them later, if he couldn't borrow them from a fellow-reporter, he had to climb a ladder to the scorers' box, access to which was thus made purposely difficult to keep out "undesirables."



Robertson, the Locomobile Winner, Receiving from Mayor the Founders' Week Cup.

Acme Moving Some on a Straightaway Stretch.

The race was unique in several respects. In the first place it was held over a course within a half-hour's ride of a city of a million and a half of people, who could reach the scene of the contest by the expenditure of a nickel. Besides, it was a practical holiday, being the last day of a most successful series of public spectacles in honor of Founders' Week. Visitors from out of town who had never seen an automobile race flocked to the park by tens of thousands. Any portion of the course could be reached via park trolleys for an additional nickel, and but for this fact and the numerous points of vantage around the entire eight miles of the course, there would have been such a congestion at the start-finish as to have seriously interfered with the race. The affair, however, was in the hands of the city. Mayor Reyburn, himself an enthusiastic autoist, felt the city's responsibility, and it was through the excellent work of the 1,500 police and Fairmount Park guards that the course was kept clear.

Quaker City Club Received Mayor's Praise.

The Quaker City Motor Club furnished the flagmen, and they and the "coppers" worked so well together that the Mayor went out of his way after the race to hunt up the Quaker club committee and congratulated them on the thoroughness of their arrangements. Almost the entire eight miles of the circuit had to be roped off, so dense were the crowds. At those points where there was possibility of an accident, the spectators were especially numerous. Sinuous Sweet Brier hill, where the Thomas went out with a broken crankshaft, was an especial favorite with the morbid bloodthirsty ones who scented a possible tragedy; so were Neill drive, and the "Y" turn at the T. A. B. fountain. Here it was that the "cops" had their work cut out for them.

The course, while well policed, was not well suited to the purposes of the speedsmiths. In the first place it was too short—less than eight miles—and had too few straights in it. Those drivers who attempted to take liberties with it suffered the penalty. Michener and his Lozier "45" were eliminated by a tricky "Y" turn at the foot of George's hill. "Mitch" attempted to take the turn at too high a rate of speed, and over the Lozier went. Thousands of the spectators who had gathered there hoping to see some such calamity rushed to the scene. Fortunately, the force of police just there was a heavy one. and they beat the crowd back while the unfortunates were being put on their feet. Neither was seriously hurt, and a few minutes later both were perched in their wrecked car smoking as unconcernedly as if a spill were an everyday affair and watching the other contestants striving for the prize they had hoped to win.

Apperson Which Figured Prominently in the Battle.

A few minutes later the little Maxwell "28" broke its crankshaft on the ugly "S" turn on Neill drive, and Bittner and Smith dragged their car to the side and watched the race from that vantage point. Then the Stoddard-Dayton was stopped for nearly an hour with valve trouble, and got going again only to be stopped on the next round by a stripped pump gear. Next the big Thomas, which had been burning things up, came to grief with a broken crankshaft while descending Sweet Brier hill. The Pullman "40," driven by La Roche, broke a wheel at the bumpy Belmont avenue crossing, and retired. The other retirals were voluntary, being ascribable to the loss of time due to tire troubles, with no hope of catching up.

The control stations were lined up for half a mile along Belmont avenue. Here it was that the men "behind the guns"—those whose work renders success possible—labored like fiends, with thousands looking on and applauding their efforts. Each time a car would run up to the long platform the crowd would surge nearer to get a view of what was doing, and the numerous "cops" on duty here had their hands full maintaining sufficient elbow room for the repair and tire men to work unhindered.

Sample Stretch of the Average Road in the Thousand-mile Reliability.

CHICAGO, Oct. 12.—Progress made in the construction of American automobiles in one year is furnished by the results of the four-day 1,000-mile reliability run of the Chicago Motor Club, which was finished last Friday and in which five of the seventeen cars that started were hall-marked perfect both for the road work and mechanical efficiency at the finish, when the technical committee made a rigid scrutiny of the survivors: two Haynes cars, a roadster and a touring car; a Pierce Arrow touring car, a Premier roadster, and a Franklin touring car, being found to be without a loose bolt or nut, without a broken part, with all wheels true; in fact, there was not the slightest chance for the technical committee to find fault. A year ago, when this same club promoted a three-day run of 600 miles and in which thirty-five cars competed, only one was found perfect at the end. There were a dozen which had escaped penalization on the road, but the mechanical examination disclosed broken parts or something loose that eliminated all but Nutt's Haynes roadster. The scrutiny of Messrs. Beecroft, Edwards, and Nadall last Friday night, however, failed to bring to light a single instance of a loose nut even on the thirteen cars examined, while it was a remarkable fact that every engine was hitting as regularly as if it had just come out of the tester's hands. That's a remarkable testimonial to the efficiency of the 1908-1909 crop of American-built cars when it is remembered that these five perfect machines had just run 1,000 miles without an adjustment, without a break of any sort, and with the motors running all the time outside of controls.

The Chicago Motor Club contest was a remarkable one in many ways, for in it were included three different angles—car reliability, tires, and gasoline consumption, in each division of which there were prizes offered.

The tire competition was entirely new in American competitions, this being the first time any promoting organization has attempted to tabulate the work of the pneumatics. It was rather an awkward proposition to tackle, but the technical committee evolved a set of regulations by which the penalizations against the different makes of tires were computed on a basis of 2 points per man per minute of labor, whether inflating or changing inner tubes or casings. No difference in penalty was imposed between punctures and blowouts, the only criterion being time spent. No additional penalties were imposed where demountable rims or quick detachables were used. Any make of tire eligible for the trophy had to be represented by two complete sets, but the only makes so represented were the Diamond and Goodrich, the former having six cars and the latter three. The Diamond was the winner, having a penalty of 11.4 points average against each tire, or a total of 274 points against the twenty-four tires. The Goodrich had an average penalty of 25, or a total of 300 against the twelve tires. The Apperson and No. 14 White, both fitted with Diamonds, went through without a puncture, or any work done on them.

While economy tests are no new propositions, the one held in connection with the Chicago run was the longest on record and shows more than any of the others, for the conditions were the same as the average tourist encounters. There was no adjustments of carbureters to make a good showing in this line, for the main consideration was the reliability end of the event, and so the contestants had to pay the greatest attention to that, with the result that the gasoline showing can be taken as an excellent criterion of the abilities of the various cars in the fuel consumption line. The trophy in this was put up by the Standard Oil Company, and was awarded for the smallest consumption under the Chicago Motor Club formula, in which the weight of the car with load was divided by the fuel consumption in ounces. Under this formula the winner was the Premier roadster, driven by Ray McNamara, which showed a pound mileage of 224.1. But the Premier also distinguished itself in the line of straight fuel consumption regardless of the formula, for it used the least gas of any, going through the four days, on 69 1-4

Perfect Score Haynes Touring Car, Wagoner Driving.

Perfect Score Haynes Runabout, Nutt D[illegible]

gallons, or an average of 15.18 miles per gallon. Altogether two main trophies were offered by the club, one for roadsters and the other for touring cars, as well as medals in the various classes, which were made according to price. The results brought about two ties in the roadster division in which the Haynes and the Premier were perfect, while there were three touring cars, the Franklin, Haynes, and Pierce-Arrow, without a mark against them. There will be no run-off, however, the club officials declaring that the cars have done all that was asked of them and that they can see no reason to ask the entrants to continue in what really means a test in which the main objects is to wreck the survivors, whereas the object of the original test was to demonstrate the efficiency of the modern car. The classes did not fill as well as expected, and in consequence there were several walkovers. Class E, for touring cars costing from $2,000 to $2,499, secured the keenest competition but brought about no winner, the Franklin and Haynes having perfect scores.

The report of the technical committee on the winners in all three competitions is an interesting one and is as follows:

ROADSTER DIVISION WINNERS.

No.	Car.	Driver.
8.	Haynes, 35-horsepower	Frank Nutt
9.	Premier, 32-horsepower	R. McNamara

Class E, for touring cars costing $2,000 to $2,499—Franklin and Haynes, perfect; Marmon, 2 points; No. 14 White, 21 points; No. 12 White, 55 points.

Class H, for touring cars costing $4,000 and up—Pierce-Arrow, perfect, won.

OFFICIAL REPORT OF THE TIRE COMPETITION.

DIAMOND CONTESTANTS—

No.	Car.	No. of Tires.	Points Penalty.
5.	Apperson	4	0
14.	White	4	0
9.	Premier	4	52
16.	Haynes	4	68
19.	Marmon	4	68
8.	Haynes	4	86
	Total	24	274

Total penalty 274 points divided by 24 equals 11.4.

GOODRICH CONTESTANTS—

No.	Car.	No. of Tires.	Points Penalty.
20.	Pierce-Arrow	4	24
7.	Pierce-Arrow	4	32
15.	Franklin	4	244
	Total	12	300

Total penalty 300 points divided by 12 equals 25 points.

Particular attention is called to the Diamond tires fitted on cars No. 5 and 14, all of which went the 1,000 miles without work of any nature being done on them. In addition to the cars fitted with Diamond and Goodrich tires, there were four others fitted respectively with Hartford, Ajax, Michelin, and Fisk tires, the last mentioned being attached to demountable rims. Their standing is as follows:

12.	White	Fisk	20
8.	Mason	Hartford	76
2.	Maxwell	Ajax	210
4.	Mason	Michelin	246

Four other contesting cars which failed to complete the 1,000 miles of the contest, or did not check into the night garage, had no recognition taken of the tires used.

Premier Perfect Score Performer, McNamara Driving.

Franklin Clean Score Survivor, Carris Driving.

Pierce-Arrow Which Survived Faultlessly, Hofmann Driving.

TOURING CAR DIVISION WINNERS.

No.	Car.	Driver.
15.	Franklin, 28-horsepower	C. S. Carris
16.	Haynes, 36-horsepower	L. Wagoner
20.	Pierce-Arrow, 60-horsepower	P. Hofmann

The final standing of the field was as follows:

ROADSTERS.

No.	Car.	Score.
8.	Haynes	Perfect
9.	Premier	Perfect
7.	Pierce-Arrow	Perfect
5.	Apperson	1 point
3.	Mason	32 points
11.	Ranier	224 points
6.	Midland	Withdrawn
1.	Reliable Dayton	Withdrawn

TOURING CARS.

No.	Car.	Score.
15.	Franklin	Perfect
16.	Haynes	Perfect
20.	Pierce-Arrow	Perfect
4.	Mason	2 points
19.	Marmon	2 points
14.	White	21 points
2.	Maxwell	51 points
12.	White	55 points
17.	Studebaker	Withdrawn

No winners were reported in classes A and F owing to the withdrawal of the Reliable Dayton in the former division and the lack of an entrant in the latter. Winners in the other classes were:

Class B, for cars selling from $1,000 to $1,999—No. 3 Mason, 2 points, winner.

Class C, for cars selling from $2,000 to $2,499—No. 5 Apperson, 32 points, winner.

Class D, for cars selling from $2,500 up—Haynes and Premier, perfect; Pierce-Arrow, 1 point.

Class E, touring cars costing up to $1,999—No. 4 Mason, 2 points, winner; Maxwell, 51 points.

RESULTS OF THE GASOLINE CONSUMPTION TEST.

No.	Car.	Passenger Load.	1st D. Gal.	2d D. Gal.	3d D. Gal.	4th D. Gal.	Weight Load.	Total Con.	Pound Mileage.
8.	Haynes	3	21	22 1-2	21	20 1-4	3,675	64 3-4	198.
9.	Premier	3	19	13	20	17 1-4	3,585	69 1-4	224.1

1.	Reliable Dayton	4	Withdrawn.						
6.	Midland		Withdrawn.						
11.	Rainier	3	Withdrawn.						
17.	Studebaker		Withdrawn.						

Upon the completion of the run Friday afternoon each car was officially weighed with its load, then sent to Eighteenth street between Indiana and Prairie avenues for the brake and clutch tests, in both of which all the survivors showed up exceedingly well. From that point the cars were sent back to the garage and turned over to the technical committee for the mechanical examination. At that time there was nine cars left with perfect road scores, but the examination put out four of them. The Pierce-Arrow roadster was penalized a point for its fan belt being off. It was lost the first day, but the car ran without one the rest of the journey, Kumpf not desiring to be penalized for breaking a seal. The Marmon lost a point for its fan belt being off, while another point was added for a leak in the air line that creates the pressure on the gasoline feed. The No. 12 White was found to have its oiler chain off the sprocket, which cost it 20 points, while another point was given for the fan being out of commission. The No. 4 Mason was penalized 2 points for the two threaded locking bushings on the front end of the rear strut rods being loose.

Only four cars were penalized during the actual run and four others met with mishaps that caused their withdrawal. The Maxwell was penalized for magneto trouble, while the No. 3 Mason was demerited on every one of the four days. The Apperson drew 22 points on the third day when it was necessary to break a seal to repair an oiler belt. The No. 14 White was penalized the fourth day when its oiler chain slipped off. Of the four cars that were withdrawn, the Reliable Dayton went out the first day with a broken frame. Six holes had been bored in it to permit of lamps being attached. This weakened it so that when the car hit a culvert near Kenosha the frame broke. The car ran the last day as a non-contestant. The Midland smashed a wheel the second ray turning off the road because of new gravel, but went in again as a non-contestant. On the fourth day it again met with hard luck breaking a frame.

"Beating it" was responsible for the Rainier breaking its frame, the car being withdrawn the second day, but going through the full 1,000 miles, being first home all of the four days. The last two days the car was driven by A. M. Robbins, manager of the Chicago branch, and it experienced no trouble. The Studebaker also was one of those to be withdrawn. Its first mishap occurred the first day when a pinnion gear in the differential was stripped through a broken ball. On the third day the car skidded on the wet cobbles in South Chicago and broke a wheel. It went through the entire 1,000 miles, however.

The first day's run was over a course taking in Kenosha, Janesville, and Rochelle, the distance being 262.7 miles. The second day the cars went via Aurora, Ottawa, and La Salle, 241.8 miles; the third day to Crown Point, Valparaiso, La Porte, Plymouth, South Bend, Michigan City, Hobart, and Hammond, 257 miles, and last to Rockford, Oregon and Rochelle, 230 miles.

SCORE OF THE 1,000 MILE RELIABILITY RUN OF CHICAGO MOTOR CLUB, OCTOBER 6—9, INCLUSIVE, 1908.

DIVISION 1—RUNABOUTS.

DIVISION 2—TOURING CARS.

Class A—Selling for less than $1,000. Class C—Selling for $2,000 to $2,499. Class E—Cars costing up to $1,999. Class G—Cars costing $2,500 to $3,999.
Class B—Selling for $1,000 to $1,999. Class D—Selling for $2,500 to any limit. Class F—Cars costing $2,000 to $2,499. Class H—Cars costing $4,000 and up.

NARRAGANSETT PARK AGAIN THE SCENE OF RACING

PROVIDENCE, Oct. 12.—The race meet of the Rhode Island Automobile Club on the mile circular track at Narragansett Park was marked by the most daring and exciting automobile racing that New England has seen, the smashing of the track records, and two accidents in which two drivers escaped death by a miracle. The meet was attended by upwards of 7,500 persons, and was a success from every standpoint. The several events were run with regularity, with not more than five minutes' wait between any two of them, and had it not been for the accidents, the meet might be classed as ideal.

Both accidents happened at the same place on the track, at the three-quarters mark, and both occurred within an hour. The first was when Joseph Wilcox, of Beverly, lost control of his machine when rounding the curve. The car crashed through the fence, plunged into a ditch, and overturned. Wilcox was thrown out and landed upon his back, injuring his spine. The crowd surged upon the track, and after being driven back by the police the injured man was removed to St. Joseph's Hospital, where he was placed on the list of those dangerously injured.

In the second heat of the race for gasoline cars of all horsepower, Arthur Lee, of this city, while leading in the first lap, struck an obstruction of some sort in the track while the machine was skidding around the same curve. The wheels were jammed, the car tipped forward, made a complete somersault, and pitched over into the ditch. Mr. Lee was thrown about twenty feet, and had he not struck clear of the ground upon which the machine fell, would have been crushed to death by the mass of wood and iron into which the car was speedily reduced. The summary:

STOCK STEAM CARS.

1.	Stanley	F. W. Marrtott	5:28 3-5
2.	Stanley	W. R. Files	6:16 2-5
3.	Stanley	A. C. Trimble	

GASOLINE STOCK CARS, 15.1 TO 24-HORSEPOWER.

THE UTILITY OF AUTOMOBILE CLUTCHES

By THOS. J. FAY, E. E., President Society of Automobile Engineers.

CLUTCHES may be classified as follows: (*a*) *cone,* (*b*) disc, (*c*) band; cone clutches may, in turn, be subdivided as follows: (*a*) metal to metal, (*b*) leather faced, (*b*) cork insert; while disc type may be classed as: (*a*) leather faced, (*b*) multiple disc, (*c*) cork insert; and band clutches may be put down as of the (*a*) constricting, (*b*) spiral, or (*c*) expanding types. Clutches, of whatever type or class, have but one prime object, *i.e.,* to enable the operator to start and stop the car without having to stop the motor. There is a secondary consideration, if we take into account the fact that it is convenient to be able to slip the clutch, on occasion. Some types lend themselves to this secondary purpose with greater facility than others, and it is also true that some clutches are most easy of application, all things considered.

With clutches, the temptation is to champion some one type. This temptation is dictated, perhaps, by limited experience, for the most part. If one becomes accustomed to using one type it naturally influences his inclinations, and he ultimately arrives at a point where he is blind to the perfection of types with which he has had the least to do. It is not too much to say, that of all the types of clutches known in connection with the automobile, none are so inferior as to fail to work, if they are properly designed. On the start, then, it is proper to point out that, in service, clutches may be of any type and still be so good as to be commendable.

Few Clutches That Are Utter Failures.

Every autoist has his preference, as is amply borne out by the fact that every type of clutch mentioned is now represented on the automobile, and the volume of business is equal to the output in nearly every case. How futile it is, then, to deny to a type of clutch the place it actually holds, in spite of the fact that one would not have to go far to find a defamer who would be willing to swear that certain types are useless. If we proceed in an unbiased manner to a full investigation of clutches, with the idea of realizing correct methods of design and with the hope of shedding light upon the materials to use, not forgetting that in the manipulation of clutches something is to be gained by favoring the several types in a way consistent with their respective characteristics, the result will be of benefit to the designer, the constructor and the user.

To show the extent to which the clutch question persists in occupying the minds of designers, it will only be necessary to relate a circumstance or two. In one of the best-known cars its design and development was attended by the construction and use of some thirteen different clutches, representing all the types known to designers. All the clutches worked so well that the car might have been put on the market, with any one of them, and have made a success. The history of several of the better-known cars is largely the same. The clutch seems to have attracted the notice of the designers with more frequency than any other one essential. In some cases good clutches were superseded by others that proved to be far inferior. Of course, this condition was not tolerated any longer than the time required to make another change.

It might be said, why make changes? Again, why stick to the "ox-cart"? It is easy to see that clutches must be a bone of contention for some time to come. When the time arrives that speed changes can be made through the clutch, then will be the time to shed the sliding gear-set, and not before. Speed changes cannot be made through the clutch as a regular and continued operation now, nor will the future be likely to afford us more kindness in this respect. On the other hand, if motors ever do become as flexible as the six-cylinder advocates say they are now, all that will be required is a clutch that will stand slipping for short intervals of time, provided the slipping can take place under well-regulated conditions.

A well proportioned motor that delivers power in proportion to speed, over a considerable range of available speeds, would come very close to the point of eliminating the gear-set, without being so over big as to debar its use. This would hold good in the cases in which the aim would be utility, rather than the maximum possible speed. In other words, if the gear ratio is fixed for moderation, and the motor is provided with a little extra power, a clutch that will admit of slipping will then do the rest. But even with all the other facilities available, it would not be wise to take to the road without the gear-set unless the clutch would lend itself to the slipping operation, as there are spots in otherwise fair roads in which cars will stick and in which the power of the motor must be exerted to the maximum. A little extra flywheel would, of course, help out. This is a facility that is rarely afforded on account of the desire to reduce weight, even if it has to be taken out of the wrong place. In six-cylinder motors, the opportunity to realize nearly the gearless condition, assuming the clutch is so designed as to afford a due measure of slipping, is a good possibility, but the featherweight flywheel generally defeats the project. The most ill-behaved car the author ever had the misfortune to kill time in was otherwise so good as to be noteworthy, barring the bucking under severe conditions, in the absence of enough flywheel to complete the cycle on the "high," in which gear it was said to be big enough to go through a mud hole.

With sufficient flywheel it would be possible to eliminate gear changes to some extent, if not entirely, provided the clutch would stand the slipping. It would have to slip to any desired degree. A "fierce" clutch would never do. Nor would one of the kind that would either hold entirely, or be entirely free. There are such clutches and they serve their purpose because the gear-set enables the operator to run the motor fast or slow, independent of the car speed, so that the power of the motor always matches the road conditions. Some clutches are prone to slip, in that they have not the requisite holding power. This is due to faulty design in every case, some difference accounting for the failure on the one hand, and the success on the other.

Why Is a Clutch Called "Fierce"?

This property seems to be characteristic of some types, and is rarely found in others. Those that are prone to exhibit this fault are kept in working order, as a rule, by taking such measures as will prevent this action, such as oiling. But others that lack the fault will hold just as well as the "fierce" kind. "Fierce" clutches are usually the kind in which the engaging movement is abrupt. In other words, from the instant of contact of the shoes to the point of "full on," the travel is short and quick. Certain toggle motions have this property. In cone clutches, certain angles are known as "sticking angles" and clutches in which such angles are found will be "fierce." Some clutches have a wedge motion, and if the wedge is so designed as to apply the pressure in a short travel, and the pressure is relatively great, a "fierce" clutch will result. In certain cam motions the same phenomenon will be noticed. The process is the same, in that the pressure is great and reached a maximum very quickly. "Fierceness" is sometimes a sign that the clutch is not powerful enough for the car. The adjustment has then to be so tight that the action is just about that which would be expected of a clutch in which the principle is wrongly applied.

A disc clutch, for illustration, can become "fierce," if the spring is too strong, the discs are too few, or of a radius less than that likely to produce good results, in the absence of oil. Without oil, this type fulfills the conditions of a "fierce," conical

clutch in that the distance (or time) of travel between initial contact and final maximum pressure is small. In a disc clutch it is the oil that introduces the factor of time since the oil has to be squeezed out from between the discs before the clutch will take hold sufficiently to drive the car. The slippery surface afforded by the lubricant will stay in place for a time depending upon conditions as follows:

(*a*) The pressure between the discs.
(*b*) The mobility of the lubricant.
(*c*) The distance the lubricant has to travel to escape.
(*d*) The unctiousness of the lubricant.

If the lubricant is lacking in mobility it will hold to a constant viscosity under the changes in temperature that are wholly unavoidable in a clutch. The absence of mobility is of greater importance than viscosity at some constant temperature. Body is something to take into account, in that the lubricant can easily have body in excess of that desired with the result that the clutch would not take a hold within the desired time, if at all. Just how slippery the surface should be, in a given clutch is something to determine, and the unctiousness of the lubricant must on that account be taken into consideration in calculating this factor.

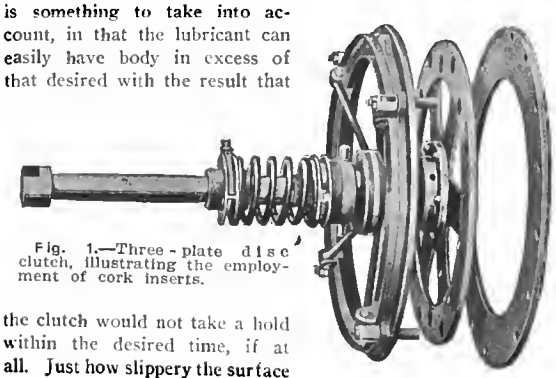

Fig. 1.—Three-plate disc clutch, illustrating the employment of cork inserts.

Clutches in which "cork inserts" are properly applied are probably as far away from the "fierce" condition as it is possible to go. Cork is a peculiar product and it performs in accordance with its peculiar characteristics. In the first instance, it has a high coefficient of friction, so that high pressure is not necessary, and its coefficient of friction is but little influenced by the question of lubrication. In other words, the cork will hold on a dry surface or if the surface is lubricated and the degree of polish of the surface is not a factor of such marked import as would be the case in the absence of the cork. High temperatures are not so prone to char cork as they would leather or fiber. This is an important matter in clutches. Even wood will be charred by the heat generated in clutches under certain conditions, which is fair evidence of the fact that the temperature can raise to a point as high as 500 degrees C.

Present Materials Not Suited to Slipping.

How futile it would be, then, to anticipate the use of leather, or fiber (compressed wood pulp), in clutches, with the idea of taking advantage of the slipping phenomenon, in the absence of change gear. Of course, cork is wood, but there is a decided difference as between wood and cork, as it is used in clutches. This will best be understood by illustrating the method of applying the cork. Fig. 1, showing a three-plate disc clutch, is a good illustration of its application; the middle disc is perforated and the perforations are filled with cork. The cork is pressed into the perforations so tightly that, in view of its elasticity, it overflows the holes and protrudes beyond the surface. As a result, the compression of the plates ends in a close contact of the cork inserts against the faces of the plates in juxtaposition, and in view of the high coefficient of friction of the cork, the negative torque of the clutch becomes a maximum.

If the pressure be great, the cork inserts compress sufficiently to become flush with the plate, but without losing the transmission value of the cork. This increase in pressure may bring the plates into metal to metal contact and if it does, the ability of the clutch will be increased. The ability of a clutch can be stated in terms of negative torque, and when the negative torque value equals the torque of the motor (positive torque) the transmission will be on a basis of 100 per cent.

In a motor the torque may be estimated as follows:

$$P = \frac{2\pi \ RS}{33{,}000}$$ In which:

P = pull in pounds (average).
π = 3.1416
R = radius of the lever arm.
S = angular velocity of the crankshaft (r.p.m.).

In a clutch, the negative torque may be estimated in the same way, taking into account the fact that a reserve factor is valuable, in order that the ability of the clutch will be well beyond the slipping point, when the motor is delivering its maximum power. If the negative torque of the clutch barely equals the torque of the motor, slipping will ensue for reasons as follows:

(*a*) Flywheel effect adds momentarily to the torque of the motor.

(*b*) The inertia component puts work on the clutch, under certain conditions.

(*c*) The condition of the clutch will not remain constant.

The best probable ability of the clutch might be regarded as that which would register a negative torque equal to about twice the average torque of the motor. This difference would be enough to insure the holding ability of the clutch, under all road conditions.

Design Must Depend on Other Features.

Let us take up one other phase of this subject, the question of the ability of clutches in the abstract, taking for illustration a clutch of say 20-horsepower at 1,000 r.p.m. It might appear at first sight as if this clutch would do for any 20-horsepower motor. But a motor can deliver 20-horsepower under several conditions of torque. In other words, the torque of all 20-horsepower motors would not be the same. The clutch, then, should be compared on a basis of torque and not of horsepower. If it is true that the negative torque of a clutch should be in excess of the torque of the motor, by an amount equal to 100 per cent., the formula would be as follows:

$$P' = \frac{2\pi \ RS}{33{,}000 \times Q}$$ In which:

P' = negative torque of the clutch.
π = 3.1416;
R = mean radius of the clutch bearing surfaces.
S = angular velocity of the clutch members;
Q = 0.50.

P' is the actual pull, and the coefficient of friction must be taken into acount in the process of determining the necessary pressure of the clutch spring. If the pressure is not directly applied, the angularity and the lever advantage must be allowed for. In a single pair of discs, pressed together by a spring, the pressure may be regarded as direct. In this case, if cork inserts are used, the spring pressure would have to be three times the value of P', on the ground that the coefficient would be about 0.33. To reduce the spring pressure, it would be necessary to do one of two things, i.e., (*a*), increase the mean radius of the members, or (*b*), increase the number of discs. Theoretically, the spring pressure would decrease directly as the discs increase, or inversely as the number of effective discs. Discs, to be effective, must be prevented from rotating.

Considering the Multiple Disc Type.

The number of discs must be limited, else the pressure between the respective surfaces would fall below the point of pressing the oil out from between them, on a basis of the reasoning as above set forth. On the other hand, the number of discs might be so great as to produce a clutching effect, due to the resistance of the lubricant used. The capillary attraction of all

lubricants is so great that the section of the lubricant is *sheared*, before the clinging effect of the lubricant is overcome. On this account, it is possible to so design a clutch using a large number of discs, that the work required to shear the numerous sections of the entrapped oil, will equal the ability of the motor, plus a reasonable reserve. In this scheme it would not be the idea to have the discs come into contact with each other at all. The slippery surface, due to the oil, would always interpose, and the oil would be the only part this would be consumed, and is all that would have to be replaced.

Some clutches of the multiple disc variety come so near to this ideal that it is necessary to select oil of a character almost devoid of unctuousness, and of almost no body. Mixtures of light mineral oil and kerosene are sometimes used for such purposes. Centrifugal force plays a part in the clutch if the radii of the members is sufficient to render this force potent. The oil is thus cast off and the members are then free to contact with each other. The phenomena termed drag is present in clutches of this character and it increases in direct proportion to the number of films of oil. This is explained in the same way that it is possible to show that a clutch can be so constructed that it is the shearing of the oil that affords the resistance necessary to set up the negative torque.

The drag is reduced if the discs are parted very much, for then the shearing moment is eliminated and molecular resistance is all there is to be overcome, again illustrating the effect of different grades of oil. While drag is a characteristic of clutches of the multiple disc genera, they are not valueless on that account, since drag can be the lesser of two evils. In the cone clutch the inertia of the mass is a detriment; the mass itself is not so great, but its radius is usually excessive. Cone clutches are from 15 inches to 18 inches in diameter and even aluminum weighs enough to be felt. It must be remembered, moreover, that the aluminum is covered with leather and the actual weight of the clutch rim is sufficient to set up a flywheel effect. This is most noticeable when the sliding gears are collided with each other. If the clutch rim is not carefully whittled down, to eliminate all possible weight, the sliding gears will soon show the effect of it.

In multiple disc clutches the radii are less, in view of the fact that the discs are about one-half the diameter of the rim of a cone clutch of the same ability. If we take into account the fact that the inertia of the mass is proportioned to V^2W (the square of the velocity multiplied by the weight), it is easy enough to see that diameter plays an important part, especially since the velocity is as follows:

$V = 2\pi Rs$ in which,
V = speed of the mass in feet per second,
$\pi = 3.1416$,
R = radius of the mass in feet (from the axis of rotation),
s = angular velocity in feet per second.

From the formula it would appear as if whittling the rim down to the smallest possible section is not nearly so good as reducing the radius as much as possible. The effect of mass is in direct proportion, while the effect of speed is as the square.

Can Slipping Be Taken Advantage of?

As clutches are at present designed, the question is, can slipping be tolerated? or, can clutches be slipped to control the speed of a car? It is believed not. The average clutch has very little of the character of the average braking system and when it comes to brakes they do not last so long that it is desirable to wear them out sooner than they will naturally need replacement. In other words, it seems quite out of the question to consider the clutches of to-day as suitable for the double purpose of clutching and speed controlling, by way of slipping the clutch at will. It is not uncommon to hear autoists talking of the multiple disc clutch as one that undergoes little or no deterioration as a result of continuous slipping under variations of load.

They seem to think that the large surface exposed, especially in view of the fact that the discs are submerged in oil, will prevent damage if the clutch is caused to slip. They forget that the discs are thin, and also that they are loose on the splines, keys, or feathers that prevent the discs from rotating. No member keyed onto a shaft will stand much abuse. This is especially so, if the member has but little bearing surface on the key. Even a considerable number of such members working in unison will fail to stand up under the work because the joint is not firm. Lost motion is bound to result in more lost motion in a short while, and in a multiple disc clutch the discs soon fray out and interfere with each other and the clutching functions, within a space of time so short as to surprise even those most experienced in the use of this type.

Tempered saw-blade steel, of some thickness, will stand quite some work of the kind in question, especially if the radius of the bore of the discs so made is considerable. If, however, the saw-blades are only one-half of the total number of discs, and the relating members are of bronze, it is not impoossible to anticipate which of the two links in the chain, as it were, will show distress, first and soon. One of the best clutches the author knows about is of the multiple disc type, in which all the discs are tempered saw-blade steel, and so designed that the pressure on the driving faces is very low indeed. This clutch runs in oil and the metal probably does not come together to the entire exclusion of all the oil, when the clutch holds and drives the car. This clutch will come near affording the speed regulating advantage, but it will give out sooner if it is caused to slip, than it will if it is confined to its legitimate function, and the difference in its life will be very great.

Slipping Cannot Be Tolerated.

Some designers are of the opinion that clutches, as now made, will stand any amount of slipping, and they will go so far as to point to their products as examples. The main trouble with some of these wonderful clutches is that they slip when they should hold, and they are also "fierce." In these clutches, "fierceness" is bound to follow adjustment, and as a result of the buffs that "fierce" clutches are heir to, the time they will stay adjusted is the time it takes to negotiate a fairly long hill of some grade pretensions. When it comes to the multiplication of driving faces difficulty is encountered in having all the faces bear equally. A dividing head on a milling machine is about the most exact device possible to use and the dividing head is not so exact as to assure equality of pressure. Even assuming that a dividing head would afford practical equality of spacing there is the cutter problem to master.

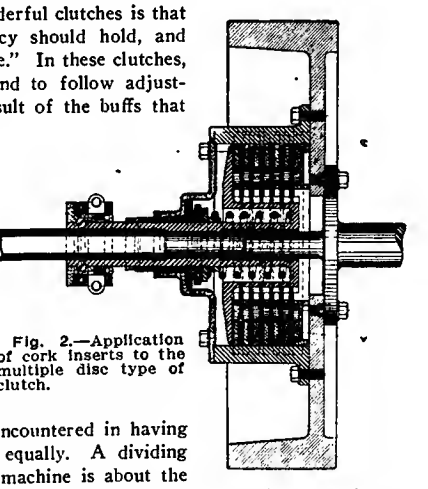

Fig. 2.—Application of cork inserts to the multiple disc type of clutch.

A comparatively small number of cork insert discs of sufficient thickness would assure immunity from key-way trouble. With a liberal section there would be little room for increasing the number, but the cork would make up for the smaller number of discs. Fig. 2 is a cross section and plan of just such a clutch and if change gears are provided to take the main work, then this type of clutch (Fig. 2) would be of excellent advantage in a pinch. There are those who think they can keep to the high gear under all and diverse circumstances. They can, to a large extent, if the clutch performance is considerably better than it is on cars that are not noted for their low first cost.

(To be continued.)

SPECIFICATIONS OF THE A. L. A. M. STANDARD SPARK PLUG

LIKE the A. L. A. M. standard screws, the standard spark plug has now been adopted by nearly all of the members of the Association of Licensed Automobile Manufacturers. The Mechanical Branch has spent much time in determining the features which it seemed advisable to standardize and in fixing dimensions. The spark plug, which has been known for several years as the "Autocar," can be described in a few words as having a ⅞-inch diameter, 18 pitch, straight thread, the form or profile of the thread being the so-called United States standard; that is, having flat top and bottom of a width of ⅛ of the pitch. This was the extent of the standard, and was really nothing more than a standard for a hole in a gas engine cylinder head. There was considerable opposition to standardizing any more than this of the spark plug. But as time went on it became clear that certain other elements of the spark plug should be defined. At first the Mechanical Branch signified its ideas in the matter by stating certain features or dimensions to be "preferred construction." However, it was some time ago decided to standardize certain further features and dimensions, still leaving other such matters as preferred construction.

The diameter of the thread, ⅞-inch, was considered necessary in order to leave the spark plug manufacturers plenty of room for insulating material in the plug. The straight thread, in combination with a shoulder or flange which seats upon a gasket close to the cylinder, always gives a gas-tight joint when the plug is screwed into the cylinder the same distance comparatively. In this connection the pitch of the standard, 18, is proper. It will be recalled that the pitch of the ⅞-inch diameter A. L. A. M. standard screw is 14, but there, another function, namely, holding power, and not a gas-tight joint, is the desideratum.

The stock used in the manufacture of the plug is 1 1-8-inch round; the hexagon head having a short diameter of 7-8 inch, being milled on this stock. This is distinguished from the construction where large hexagon-shaped stock is taken, and the part below the head turned down to a cylindrical surface. The shoulder, which is intended to seat upon a copper-asbestos type of gasket, has the same diameter as the round stock from which the plug is made, and is 1-8-inch thick or deep, having a face seating upon the gasket 1-8-inch wide.

The blank, or portion below the shoulder or flange, has a minimum length of 1-2-inch. The dimensions of this portion of the plug cannot be standardized owing to the requirements of the different types of engines, as water-cooled and air-cooled, and those having different thickness of water jacket, etc. There was considerable sentiment against even stipulating a minimum dimension for this blank on account of the tendency of any specific dimension to become standard, although intended only as a minimum or maximum. However, it was finally decided that it would be necessary in this case to specify a minimum dimension, in order to insure that in any case the blank would have a sufficent number of threads.

The question of whether the spark plug should have a recess adjacent to the shoulder was a subject of sustained debate. In this connection, previous current practice had material weight, as omitting the recess contemplated counter-boring the cylinder, whereas many thousands of engines which had been in use for some time were not counter-bored. In determining the diameter of the packing-gland nut head, that is, the separable portion of the plug which holds the insulation in place, one determining factor was that the distance across the corners of this smaller hexagon should be less than the distance across the flats of the larger hexagon, in order to make possible removing the plug from the engine with a socket wrench.

From the above it will be seen that all the essential features for a standard spark plug have been settled upon. At the same time ample leeway has been left in the matter of details to leave play for that competition which is characteristic in the business of the members of the Association of Licensed Automobile Manufacturers, and to leave the gates open for joint active inventive genius which is constantly perfecting such details.

CALL FOR COMMERCIAL VEHICLES IN THE FRENCH CAPITAL

PARIS, Oct. 3.—There are possibilities of an almost complete revolution in the building trades of Paris by the decision of the Builders, Contractors and Masons' Association to hold a competition for mechanical substitutes for three types of horse vehicles at present extensively employed. During the building of a very extensive subway, motor trucks have been employed almost exclusively for the removal of earth from the mouth of the boring to barges in the river. It is doubtless as the result of this successful work that the builders have decided to encourage the development of mechanical vehicles for the transport of large blocks of stone and for building material in general.

The first of the three types for which a mechanical substitute is requested is a two-wheeled, low-built wagon fitted with a bogey operated by a windlass, and used exclusively for carrying blocks of chisseled stone as used for foundations, facings, etc. The mechanically operated vehicle must be able to carry a load of five tons, must have metal-shod wheels, easy means of loading and unloading, an engine-driven windlass to help it out of difficult ground and a speed of not less than six miles an hour.

The second type is a long-bodied two-wheeled cart, enclosed at the sides, but open front and back, for the carrying of planks, scaffolding, ladders, and other cumbersome material. Its load capacity must be four tons, and its speed six miles.

The third type has a substitute already found in the tip wagons now extensively employed by large contractors. The regulations stipulate a vehicle capable of carrying five to six ton loads of sand, gravel, earth, etc., and of tipping them either at the rear or the side.

A ten hours' test under normal working conditions will be held for each of the three types, during which a minimum speed of six miles an hour must be maintained. It is stipulated that the motor trucks must accomplish all that the present horse vehicles perform, but full liberty is also left to designers to introduce improvements in the handling of loads. Rubber tires are barred, on account of the rough ground on which the vehicles will generally have to operate. An efficient winch, driven off the motor, is considered essential in order that there may be no difficulty in getting the vehicles out of the rough ground of building yards. The Builder's association guarantees to purchase the most successful vehicles taking part in the competition. The importance of the field thus thrown open to mechanical transport can be appreciated by the fact that the amount of material transported annually by the Paris building trade is estimated at not less than five million tons.

It is proposed that the 1909 Prince Henry touring competition shall be under the auspices of the German, Imperial, Bavarian, Austrian, and Hungarian automobile clubs, and that the event shall extend over six days. The projected route is from Berlin to Breslau, Brunn, Budapest, Vienna, Salzburg, and Munich, where the contest will end.

LETTERS INTERESTING AND INSTRUCTIVE

POINTS CONCERNING THE LAWS OF PHYSICS.

Editor THE AUTOMOBILE:

[1,583.]—Can modern automobile designers reverse the laws of physics to suit their passing whims? This question may seem absurd on the face of it, but my reason for asking it is because I notice in the epecifications of the Cbalmers-Detroit "30" and the new Columbia 30-horsepower model both bave exhaust valves considerably smaller than tbe intake valves. Tbis seems to me to be contrary to common sense, because tbe very cause for the engine's operating is the increase in volume of the gas after it is drawn into the cylinder. As no engine expands the gas down to atmospheric pressure or cools it to its original temperature, it is evident that tbere is more gas, by volume, to be exhausted than was drawn in. As this is tbe case, how can an engine with exhaust valves smaller than tbe intake work to best efficiency, especially at high speeds? If the intake valves were of the automatic variety, this combination of large intake and small exhaust is all right, because an automatic intake is more or less of a throttle, thereby cutting down the supply of gas; but on both the engines above mentioned the intakes are mechanically operated, hence none of the throttling. I do not mean to infer that I think the intakes too large, but that the exhausts are too small. This question of valve size may be a question for the designers to answer, but if you can I wish you would explain why they uss intakes larger tban exhauste.

Hoping that tbe designers of the above-named cars will see their way to explain this detail through these columns, I remain,

Worcester, Mass. FRED B. FAY.

In jumping to the conclusion that the designers in question have reversed a law of physics, you have apparently overlooked one of them yourself. The cylinder contains many more volumes at the end of the explosion than at the beginning due to the fact that the gas is under *far greater pressure;* hence, it escapes far more quickly. This is further aided by the fact that the lift of the exhaust valve is greater than that of the inlet in the two cars you mention, and this adds greatly to the effective opening of the valve port. The inlet valve is always made as large as possible in order to inspire the maximum charge, owing to the slight impelling force set up by the suction, and also to overcome the phenomenon known as "wire-drawing" at the higher speeds. But as its diameter is increased, the lift of the valve is decreased correspondingly. It is not merely a question of handling two volumes of widely differing proportions, but also one of the manner in which they are moved.

STEERING CONNECTIONS—DIFFERENT PLACING.

Editor THE AUTOMOBILE:

[1,584.]—Please tell me through "Letters Interesting and Instructive" why the connecting arms of automobile steering knuckles are bent toward eacb other when connected behind the axle and vice versa when connected in front?

Seattle, Wash. STEERING KNUCKLE.

The theoretical requirements of a perfect steering gear are that all wheel axles, when produced, *i.e.*, extended on the drawing board, should meet in a single point, but this is not carried out in practice. The rule now followed was introduced by one of the pioneer French designers, and consists of giving the steering knuckle arms such an inclination that when produced, they will meet at a point representing the center of the rear axle of the vehicle. It will be evident that in order to comply with this requirement, the steering knuckle arms, when placed forward, would have to represent a continuation of the lines passing through their centers when placed behind the axle. The reason for favoring a forward placing of the cross connecting rod of the steering gear, is that it is then under tension for most road shocks, beside giving a somewhat better action of the wheels where side slipping is concerned, and offering a slightly greater angular range than when in the rear. The chief reasons for placing it in the latter position are the improved appearance and greater protection thus gained, an increased angular range being obtained by narrowing the frame forward.

WANTS INTERNATIONAL BUGGY DESCRIBED.

Editor THE AUTOMOBILE:

[1,585.]—I am a subscriber to "Tbe Automobile" and I see that many automobile manufacturers are giving detailed reports on their machines in your magazine, ebowing all points about their macbines. I own an International bigh wheel auto-buggy, and bavs been eagerly searching for a good write-up and explanation of the International, but have looked in valn. I write to ask you to approach the good people of the International Harvister Company of America, to give the pubiic a good, explicit, and thorough explanation of tbe auto-buggy, as I believe that all owners of International auto-buggies, and others, would appreciate and read with interest sucb an explanation, for the reason that I believe most of such owners are amateurs, and it would be a good iesson for us. Get after tbe manufacturers, and have them come out in dayligbt and tell us what they know about their product.

Buffalo Lake, Minn. MRS. F. G. NELLERMOE.

Such an appeal, particularly when coming from an owner and driver of the fair sex, should certainly bring the desired result at a very early date, and we would accordingly refer it to the manufacturers of the International. If they will supply the necessary information, it will be given due attention in the near future. There are probably a great many other amateur owners, and not all of them owners of the high-wheel buggy type of automobile who would be pleased to learn a great deal more about the machines they own, so that makers and publicity men might take the hint and depart slightly from stereotyped descriptions.

A MONTANA MAN HAS HIS SAY.

Editor THE AUTOMOBILE:

[1,586.]—Referring to "Letters Interesting and Instructive," Nos. 1534 and 1553. In the former a typographical error would seem to bave crept in, as you state "coefficient is not as high as when two similar metals are used," wben the rest of tbe article would show that you had intended dissimiiar. In No. 1553, Mr. Rhodes takes you to task on your answer to "Brakes." My idea of "Letters Interesting and Instructive" is a source of aiding those who want to know, and not a meane of pulling and splitting hairs. Am I right? It would eeem to ms that your statement as to the "why" of using dissimiiar metals for brakes is concise, and I know it to be correct. The reason for using Babbitt and other white alloys is that they heat less, despite the fact that their coefficients of friction are to all intents and purposes the same as the harder metals, and that they lend themselves more readily to the inequalities of the driven or driving shafts.

Mr. Rhodes states that the sole reason for using different or dissimiiar metals is that they would wear too fast; this is not tbe sole rsason, with due respect to Mr. Rhodes. Friction is greatest with soft and least with harder metals; bronze is employed because it is softer than steel or cast-iron, and is still very tough; steel against steel would heat too rapidly and still would not give the required friction, except with greatly increased pressure over steel and bronze. As to the two flies, this only illustrates the rsiative positions of the fibres of the metals under consideration. It will be seen that two like metals will wear in the fibre evenly and the grains come to an amicable understanding, thus giving no resistance, while two dissimiiar metals will always be wearing in this respect, thus producing friction.

No. 1537. Possibly the fault is to be found in the msthod of driving. I have noticed that the average driver does not control sufficiently by spark advance and retard. If the escape screw on the carbureter is regulated to feed an average amount of gasoline, then by leaving the throttle down to the last notch on tbe ratchet and controlling by spark, the driver will find not only perfect control, but a very material decrease in fuel consumption. This does not mean that the throttle is not to be used at all, but on the contrary, that where the driving is being done on the nearly level stretches the throttle is to be closed, sxcept for the amount provided by the escape screw. In teaching to run, this seems to be the most difficult point to impress upon the minds of those learning, that "except in speeding and hill climbing, close the throttle to the last notch and accelerate entirely by means of the sparker; when more power is needed, leave the spark advanced and use a little more gasoline." Drivers of two-cylinder cars will soon find the advantage, and those of four and six-cylinder in direct ratio to the number of cylinders employed. They will also find that this method will put them close to the five-mile limit on high, as the advanced spark will give the required time for complete combustion in the cylinder chamber, thus utilizing all the gasoline energy

of a weak mixture. Would like to hear from a few who try this for the first time, as their experience should be interesting.

No. 1547, Ideal Car. May I take exception to three of the points? First, water cooling is not ideal, by reason of the fact that it necessitates the loading of the machine with dead weight in the way of the water carried. Would advise Mr. Lloyd to look into the Franklin, Cameron, and other air-cooled care. Second, two flexible joints are not necessary; one is all that is required, as in the Rambler. Flexible joints use considerable power. Third, the wheel base of 124 inches is excessive. How would one get around some of the sharp curves to be found on many of the roads in the country? This long wheelbase would make rapid work in cities very difficult, if not altogether impossible.

No. 1549. Mr. Evarts has mixed his dates a little. In railway and other grading the per cent. of grade is figured from the feet of rise, in each 100 feet on the level or horizontally by the engineers, though they may, of course, go it backwards, as has Mr. Evarts. Per cent. of grade is equivalent to the number of feet of rise in each 100 feet of the horizontal; thus 1 per cent. is a rise of 1 foot in 100 feet on the level; 10 per cent. is 10 feet rise; therefore, 100 per cent. would be 100 feet, and if he will take the trouble to draw the triangle he will find that this resultant is 45 degrees and not 100 per cent. of 90 degress, which comes to infinity, as you state. Hope that pie did not hurt the rest of the party.

It looks good to see at least one automobile manufacturer come down and be friends with the trade. Thank you, Mr. Duryea. Guess this will be enough for one week from

Butte, Mont. MONTANA.

A VALUABLE SUGGESTION FOR CLEANING.

Editor THE AUTOMOBILE:

[1,587.]—If you think the following suggestion would be of enough interest to your many readers to publish it, you are at liberty to do so. In 1900 I purchased my first automobile, since which time I have owned from one to three machines at a time. At the present I am the owner of two, a runabout and touring car. Yes, I have employed chauffeurs at different times, to my personal expense and regret, but for the past two years I have used my handy man about my country home for the care of my machine, such as washing, cleaning the brass, and keeping them in good shape, with instructions at the same time to clean the grease from the engine, but this latter part, for some reason, is usually neglected, and from time to time I find it necessary to roll up my sleeves and with the aid of my handy man, give my engine and other working parts a thorough cleaning.

Only a few days since in going over and cleaning the grease from the engine, shafts, and other parts, I commenced with a can of gasoline and a paint brush, and after more than an hour's hard work I managed to remove a good portion of the accumulated grease and dirt, and after another hour's hard rubbing with waste, rags, etc., I succeeded in doing a job which would pass inspection, but after finishing I noticed there were certain parts of the engine and under parts of the differential gears and placee which were hard to get at, had not been properly cleaned, largely on account of their inaccessibility. Just at that stage of the cleaning process I happened to notice a brass hand torch, or so-called plumber's gas furnace, such as is used for heating solder irons and found in most garages, and right here is the point of my suggestion. I pumped it up to give as much pressure as I could by hand, opened the valve and found I had a good strong pressure, and was surprised to see how rapidly and thoroughly it removed all the grease from parts which I could not get at otherwise, such as bolt heads, small screws, and other parts which were impossible to reach by hand.

The thought occurred to me, if some inventive genius could get up a suitable spray used in connection with a compressed air tank suitably arranged with connections and a tube, that it would be a quick and easy way to clean grease and dirt from the engine. Everybody knowe the process of whitewashing and painting by spraying, also the familiar process of sand-blasting for cleaning the fronte of buildings, and the thought occurred to me, if something could be invented to use as a spray with gasolene, that it would be a boon to automobile owners as well as chauffeurs, as the cleaning of an engine could be accomplished in not only a quarter of the time, but in a more satisfactory manner. If you think the suggestion practical and any inventive genius cares to take advantage of it, he is welcome to it. THOS. C. SNEDEKER.

New York City.

WHAT ONE MAKER'S TRUCK DEMONSTRATES.

Editor THE AUTOMOBILE:

[1,588.]—You might be interested to know of an experience with one of our three-ton trucks last week. This machine is hauling lumber twenty-two miles, from Tully to the Solvay Process Co., Syracuse. The machine is making one round trip a day, or about forty-four miles, and is hauling from four to five tons of lumber. The total load of approximately 15,000 pounds is so much greater than the roads are accustomed to that the towns have been obliged to replank the bridges along the way, one after another, because of the danger of the truck breaking through. Last week, while coming out of the Solvay property at Tully, with a five-ton load of plank, it was necessary to cross a wooden bridge which spanned a narrow ditch. When the rear wheels struck the bridge, the driver felt something go, and the bridge and machine settled gently on one side and the truck and load turned completely bottom side up in the ditch. The truck was released from its load, and in some way was righted. We give our driver credit for a pretty clever piece of work in getting this machine on its legs again without a particle of equipment of any description to assist him.

Examination showed that only about one gallon of gasoline remained in the tanks. Because the car being completely turned over, the gasoline had escaped through the vent holes in the top of the tanks. As far as the driver could discover, the machine looked all right, and, on trying the engine, everything appeared O. K., and so he put his five-ton load on again and started for Syracuse. After a short distance his gasoline gave out, and he was hung up for two or three hours until a passing machine loaned him fuel enough to bring him to the city. The truck finished its trip as usual, and, so far as we can discover, there was not the slightest damage sustained by the machine in its upset.

We think that this is a most remarkable demonstration of the flexibility of the wood-slil construction of the Chase truck, as we do not believe any steel frame could have withstood the enormous twisting action caused by the rear end of the truck tipping over and pulling the front with it. As compared with the horse, we think that a mix-up of this kind would have resulted in about as spectacular a runaway as could have been desired.

Syracuse, N. Y. CHASE MOTOR TRUCK CO.,
S. M. CHASE, Pres.

BRITISH MANUFACTURERS AND MOTOR RACING.

Editor THE AUTOMOBILE:

[1,589.]—The views which have been expreesed with regard to dangerous motor racing have interested and impressed me greatly.

There can be no doubt that the rapid development of the automobile has in the past been very largely due to racing, and the public undoubtdly then took a great interest in it; but recent utterances have devioped the fact that there is now an immense volume of public feeling against dangerous racing, and that there is a general idea that the automobile is developed and estahlished so sufficiently that racing demonstrations of an extreme type ere no longer neceesary.

As one who has been responsible for most of the racing in the Britisb Isies, I think it may perhaps be my duty in deference to public feeling to be the first manufacturer to publicly announce my intention of withdrawing Napier cars from all dangerous competitions.

In making this announcement I hope the public will accept my assurance that my sole object in automobile racing in the past was to demonstrate the ability of a British manufacturer to hold his own in this high type of engineering against any one in this world, notwithstanding the long start our faulty legislation gave our foreign competitors in this great industry. I feel that that object has now been achieved, and that the British motor-car now leads in type, design, and workmanship.

This matter is a serious one for the manufacturer; and it is possible that abstention from racing contests may, as some think, react upon my firm. I must therefore qualify this declaration of my withdrawal from abnormal contests by claiming liberty to lead the way again if I have mistaken the trend of public feeling.

London, England. S. F. EDGE.

WHAT IS NORMAL COMPRESSION?

Editor THE AUTOMOBILE:

[1,590.]—In the September 10 issue under the head of "Suggestions for the Man Who Drives His Car," by Thos. J. Fay, he uses the expression: "Compression is normal." How do you determine this and by what instruments?

Kingman, Kas. GEO. C. TREDICK.

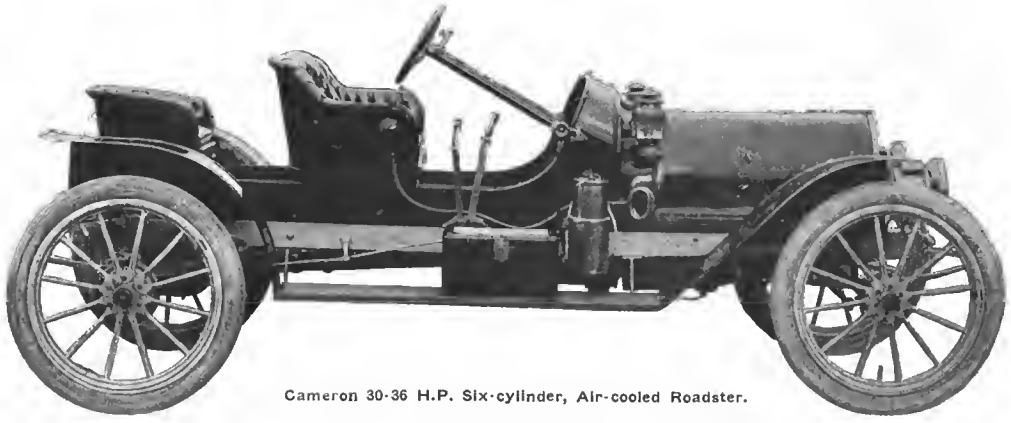
Normal compression in any given design of motor would be the compression (cold) fixed by the designer by the relation of the sweep of the piston to the clearance space. Normal compression is not the same, as measured in pounds per square inch, in all motors. The normal compression as against "loss of compression" would be evident to a motorist in the act of cranking. Were the compression to become abnormal, as a result of carbon deposit, it would be rendered manifest by knocking on a gradient or by way of pre-ignition.

The cold compression can be found by means of a "gauge" reading to about 90 pounds per square inch. Screw the gauge into the threaded hole, normally used for the spark plug. Another way is to use a spring balance, hooked to the starting crank, and by a steady up pull, against the compression, the pull in pounds resultant of the compression may be noted.

THOS. J. FAY.

Brooklyn, N. Y.

CAMERON AIR COOLERS IN 4- AND 6-CYLINDER MODELS

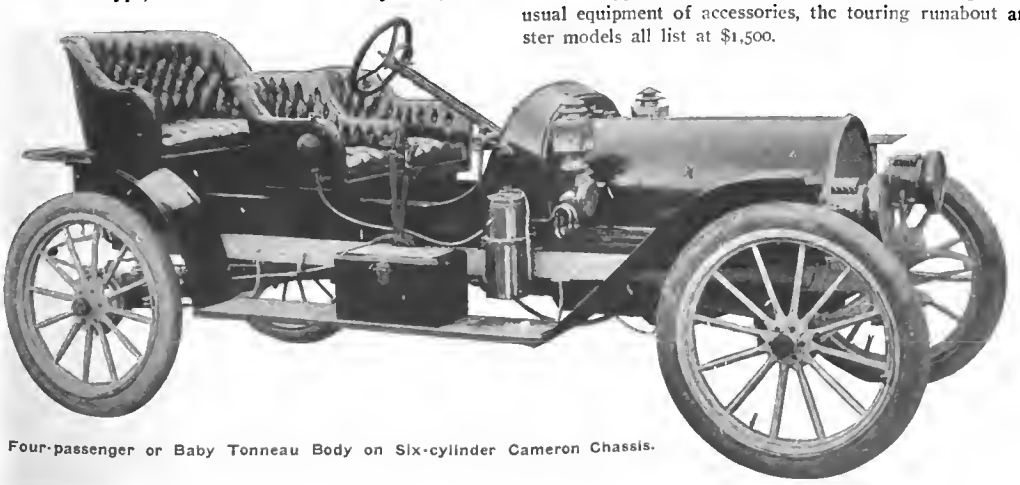


Cameron 30-36 H.P. Six-cylinder, Air-cooled Roadster.

FOR the coming season the chief representative of the Cameron air-cooled line of cars, made by the Cameron Car Company, Beverly, Mass., will be a machine of the six-cylinder type, which will be placed on the market at $1,500. As a matter of fact, this new Cameron, which is known as Model 11, is already on the market. The motor is of the well-known air-cooled type that this concern has been turning out for the past six years, and has undergone practically no changes in the 1909 model, with the exception of improvements here and there that are the result of experience. The six-cylinders are cast independently, the valves being placed opposite each other in the head, thus obtaining all the advantages of a direct placing in the head, and at the same time making a smooth chamber inside the cylinder, with the added benefit of permitting the cool air coming through the inlet to keep down the temperature of the exhaust, this valve arrangement being responsible for the great fuel economy of the Cameron motor.

The crankshaft is a one-piece drop-forging supported on four ample-sized bearings of Parsons' white bronze, the big end bearings of the connecting rod also being of the same metal, the bearings themselves being die cast. Both cylinders and pistons are cast from very hard, fine-grained gray iron, and this is also true of the piston rings. The wrist pins are unusually large and are ground to a perfect fit. The cylinder dimensions are 3 7-8-inch bore by 3 1-2-inch stroke, and the motor develops its rating of 30-36 horsepower at a moderate normal speed. A dual system of ignition is fitted, employing the Remey high-tension magneto, which is included in the list price. The clutch is of the internal conical type, self-contained in the flywheel, thus doing away with all end thrust. Drive is by means of a propeller shaft through a single universal joint to a unique type of selectively operated sliding gear-set giving three speeds and reverse. This is a special design of transmission that has been developed by the builders of the Cameron cars and is one of the strong features of their machines. It is built integral with the rear axle, the pinions and shafts being made from high-grade chrome nickel steel, supported on imported annular ball-bearings. The latter are also employed on both the front and rear wheels and in the rear axle driving unit, the only plain bearings being in the motor. The forward axle is a piece of seamless steel tubing, the knuckles, steering arms and connections all being substantial drop-forgings; the driving axle is of the floating type, the entire load being carried by the housing tube, while the driving shafts are of chrome nickel steel.

Two sets of brakes are combined in the same drum, mounted on the driving wheels, the service brake consisting of a thermoid-lined hand contracting on the drum, while the faces of the emergency brake are malleable iron against steel, the former constituting the shoe, which expands against the inner face of the steel drum. Full elliptic springs are used on the rear and three-quarter elliptics on the front, making the car very easy riding for its weight, which is but 1,650 pounds in the touring type. The steering gear is of the enclosed rack and pinion type. Wheelbase is 112 inches and the tread is standard, but the 60-inch southern tread will be provided on order. Tire equipment is 32 by 3 1-2 inch all round on all models. The touring car is capable of 50 miles an hour, and the runabout and roadster types of 60 miles. Complete with magneto and the usual equipment of accessories, the touring runabout and roadster models all list at $1,500.



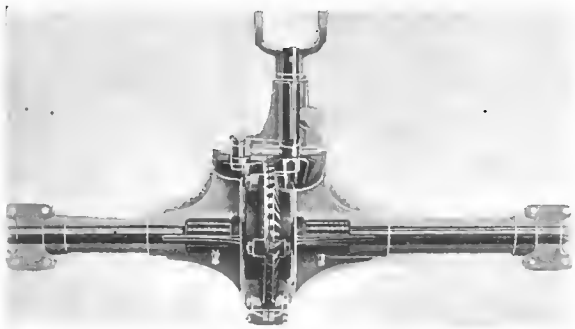
Four-passenger or Baby Tonneau Body on Six-cylinder Cameron Chassis.

Maxwell Model A, 10-Horsepower Junior Runabout.

MAXWELL JUNIOR RUNABOUT FOR 1909.

As a leader for its 1909 line, the Maxwell-Briscoe Motor Company is planning to build no less than 5,000 10-horsepower runabouts, which will be marketed at $500 each. The foregoing illustration of this new car, known as Model A, shows that it closely follows the lines of its predecessors in the Maxwell fold. and a review of its specifications makes this even more apparent. As a matter of fact, it is practically a replica of the 12-horsepower Maxwell that has been on the market for several years past and which lists at $825, the chief difference between the two cars lying in their size. The two-cylinder motor is of the horizontal opposed type, and its cylinder dimensions are 4 by 4 inches, its rating of 10-horsepower being delivered at 1,500 r.p.m. The valves are mechanically operated and the cams and camshaft, contained in a separate housing, are removable without disturbing the timing. The entire motor is protected by a sheet metal pan extending from the radiator to the dash.

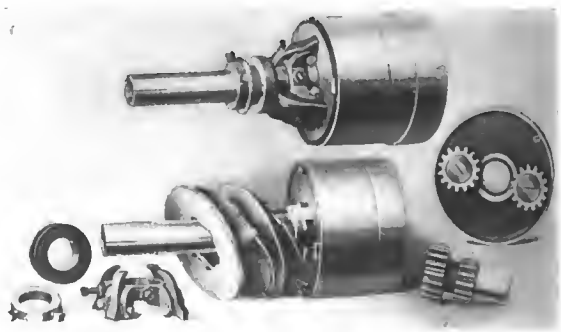
The carbureter is of the standard Maxwell, float-feed type.



A View of the Maxwell's Rear Axle and Connections.

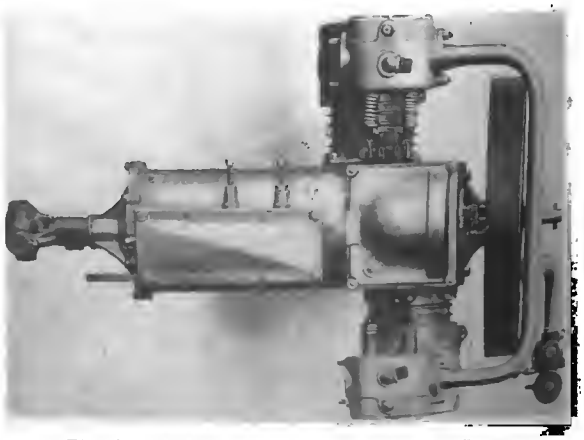
while ignition will be of the high-tension order, employing a double unit coil on the dash; a compression oiler located on the forward face of the dash under the hood, with three sight-glasses on the dash proper, will take care of the lubrication. For cooling, the thermo-syphon system used on the other Maxwell cars, is employed, with a honeycomb radiator. The same type of multiple disc clutch is also used, the gear-set being of the planetary type and providing two forward speeds and reverse, both the clutch and the gear-set running in a bath of oil. Final drive is by shaft to a live rear axle, there being two universals between the gear-set and bevel gear. The frame is of pressed steel, hot-riveted, while the running gear will consist of 28-inch wheels with 3-inch tires of the clincher pattern. The suspension consists of full elliptic springs, both front and rear. while the wheelbase is 82 inches, and the tread standard. The brakes are placed on the driving wheel hubs and are double-acting. A 10-gallon gasoline tank is provided, while the radiator holds 2 1-2 gallons of water, and the oiler one quart, or sufficient for 100 miles. The weight, all on, is 1,100 pounds. A metal body of the runabout type with a divided seat and an open deck in the rear provides accommodation for two.

In its preliminary announcement concerning the newcomer, the Maxwell-Briscoe Motor Company makes a very interesting comparison between the initial cost and the expense of maintaining a horse and buggy as compared with running a Maxwell Junior runabout for a year, conceding, of course, that any automobile would be used so little that its total mileage for a year would be but 1,000 miles, which is said to represent the average travel of the individually owned horse rig in this country. Rather a significant fact in this connection is the citation from the government statistics of the figures covering American carriage production, which show that very close to 1,000,000 carriages of all kinds are turned out by American makers annually. Of these, 770,000 in round numbers are of the one-horse buggy type, which may best be compared in first cost and expense with an automobile of the size of the Maxwell Junior. Figuring depreciation and interest at the same rate in each instance and charging the usual prices for supplies and repairs in the case of both the horse and wagon and the automobile, it is calculated that it costs the average horse owner $375 to cover 1,000 miles in the course of a year, at an average speed of eight miles an hour, which is high, as the usual horse-drawn vehicle seldom averages better than six miles an hour, even for comparatively short distances, while on a long run this would naturally be less.



Showing the Planetary Transmission Assembly.

On the other hand, the Maxwell Junior is capable of speeds ranging from four to 40 miles an hour, and in the hands of the average horse owner in the country would probably cover 1,000 miles every three months, due to its far greater range of travel, making convenient and easy visits that are practically out of the question with a buggy, owing to the distance. To cover 1,000 miles with the Maxwell the makers figure would cost $108, which could be spread over a year or not as the owner desired.



The 10-Horsepower Motor That Furnishes the Power.

Autoing's Limitations In Uruguay

By Sigmund Krausz

One so called road

One real road

Uruguayan farm houses

The old and the new

MONTEVIDEO, Uruguay, Sept. 1.—Upon unpacking my car in the customs house at Montevideo I found that one of the fenders had received large rust spots through some corroding liquid which had run over it. They said it was saltwater, but how in the world saltwater could have penetrated into the tight case is more than I can understand, for they pack well at the Dayton factory, as I had learned through actual experience at Havana and Rio de Janeiro. However, the damage was so well repaired by a native firm of coach builders that I can only pay them the highest compliment.

This matter was not the only thing, though, to ruffle my temper at the customs house. While I was not subjected to so much running from Pontius to Pilate, as in Rio de Janeiro, I was told, to my great surprise, that there was a duty on automobiles in Uruguay. I had been informed just to the contrary by the consul of that country in New York, whom I had interviewed shortly before shipping my car. True, the duty is not prohibitive, but it is always a disappointment to have to pay for something which you expected to get for nothing.

The worst thing, however, was to come, before I could clear my car entirely. There was a charge for lighterage against it, and this lighterage amounted to more than the whole freight charge from New York to Montevideo. While the latter was only slightly over $100, the robber barons of the lighter trust—for there are trusts down here as well as in the United States, although they operate under different names—demanded more than $125 for taking the car from the big steamer to the dock, and there was a charge of another $20 for hauling it under cover to the customs house.

I tried to protest, first mildly, then energetically, but to no purpose. The company would listen to no protestations; there was a fixed tariff, they said, and since the law gives them a lien on the goods until the charges are paid, there remained nothing but to "cough up," as they say at home.

After these gall-raising experiences, I was somewhat recompensed by finding an excellent up-to-date livery garage—by the way, the only one in Montevideo—where I was able to hire a closed stall, including cleaning of the car for a price which I do not care to mention, for fear it would bring the blush of shame on the cheeks of some of our garagemen in the United States. At the same place was an excellently equipped machine and repair shop, for which, however, I have so far never had any use, in spite of some considerably hard driving.

I wish to dwell a little on the fact that, whereas I had a lot of trouble and waste of time in Rio de Janeiro before I could get a license for car and driving, this matter was arranged here with slight effort, and, what is more, there were no fees and taxes connected with the procedure. In the Brazilian capital they had amounted to more than $60. But, then, they do not have to support such a lot of loafers here as one finds in the municipal offices there.

This garage, being the only one in town, as mentioned above, I had immediately a chance to get fairly well acquainted with the types prevailing in Montevideo, a city of about 300,000 inhabitants. They are French, French, and again French, with a slight sprinkling of English, German and American machines. The latter are nothing to be proud of, however, consisting of a few cheap vehicles. No wonder there is a prejudice against them when one sees them running next to such machines as Renaults, Panhards, Mercedes, etc. The Stoddard-Dayton was an eye-opener to the connoisseurs and laymen here with its first appearance on the street, and even the daily papers noticed the fact that there was "a new coon in town."

The majority of Montevidean cars are of the limousine type, though why this should be is a conundrum, since they have only two to three months of so-called winter here. During the rest of the year it is warm and hot. Just now it is the winter season, but aside from rainy days, there is nothing in the temperature to indicate this. There is no frost and the temperature does not range lower than 10 to 15 degrees above zero (celsius). It can, in my judgment, therefore, be only the characteristic hankering of the Latin-American race to "show off" which makes the limousine popular.

I don't expect that the auto sport will ever take deep root here, as there are no attractive drives within the city limits. The pavement of the streets, too, on which, by the way, you have to drive on the left, is not too seductive. It consists of

granite blocks, not badly laid, but still this is not the ideal pavement for motoring. Another thing which does not tend to make auto driving in the city enjoyable is the number of big heavy electric street cars which shoot past the crossings at an amazing rate of speed. Why they should be allowed such speed in narrow, rectangular streets is more than I can comprehend, when the limit for automobiles is to about seven miles within the city. The Prado, a small park, and the Parque Urbano are the only places where one can drive without having his nerves at high tension all the time. But there is not a mile of driving in the two parks together.

On the other hand Montevideo has a great advantage over Rio de Janeiro. It has at least some good macadamized country roads in its immediate vicinity. There are several of them in various directions, on some of which, I am told, one can get as far as 50 kilometers from town. I have tried several, for example, the ones leading to the Barra Santa Lucia, to Colon, and to Pando, a village of about 35 kilometers from the city.

The Barra Santa Lucia is a pretty river scene, which I could only admire from some distance, as the road at its end was torn up by repairmen and the heavy rains of the preceding two or three days had made the mud there knee-deep. Having several guests with me, among them ladies, I did not care to get "stuck," and gracefully yielded to the request of the latter not to go any further. The stopping place is pictured in one of the photographs accompanying this article.

The drive to Pando, however, proved more enjoyable, in spite of various adventures, and, it is of this I want to speak now. I had invited Mademoiselle Mathilde de Lerma, the celebrated Spanish prima donna, who is at present singing in Montevideo, and who wants to take a Stoddard-Dayton machine with her back to Spain, to enjoy a spin with me in the country, and there were several more in the party. We started from the Hotel Lanata, where we all stopped, and soon gained a fairly good country road a short distance from the city limits. It was a magnificent day, corresponding to our late October days, and the air was filled with ozone. Past avenues of eucalyptus trees, large cactus hedges, and American barbed-wire fencing we went at a moderate speed which allowed us to admire the undulating landscape, with its scattered adobe farm houses off the road, the numerous cattle grazing on the *estancias*, and here and there, the distant view of the La Plata river, which is here about 80 miles wide and looks certainly like the ocean.

From time to time we met heavy two-wheeled carts drawn by four or six oxen, or three horses harnessed abreast, on one of which the driver was riding. The wheels of these carts were not less than 6½ feet in diameter, and, although these vehicles are not heavy and do not carry great loads, the thick mud covering the hubs and spokes plainly indicated the reason why so many draft animals were attached to them. As a rule, the lanes and side roads of Uruguay are either a sea of mud or sand, and I would not advise any automobilist to leave the main roads around Montevideo for exploring purposes.

The majority of the animals we met were evidently not used to the sight of an automobile, and more than once they turned the carts into the shallow ditch beside the road, in spite of the efforts of their drivers and our own moderation of speed and noise. Frequently we stopped the motor altogether to allow the frightened beasts to pass. This we had to do specially when we met a *gaucho* on a young and refractory horse. These Uruguayan cowboys in their wide trousers and flowing *ponchos* are picturesque characters, and only their splendid horsemanship enabled some of them to keep the saddle while their mounts shied and reared at the puffing and whirring of the approaching auto. By stopping the car and allowing a horse-drawn vehicle to come out of a lane and up to the automobile I was able to take a picture showing the modern and ancient method of transportation in South America.

Once we met several oxen and cows crossing over the road. We approached slowly. Then, two or three of them stopped in the middle of the road turning their heads in our direction. As we came nearer one of the beasts faced the car, and, lowering its head, prepared to charge. The two ladies of the party uttered frightened shrieks, and I saw already in my mind a smashed radiator and an aching bull's head, when the chauffeur pressed the exhaust pedal and the sudden gunfire-like clamor frightened the animal so that it turned tail and jumped over the cactus hedge lining the road. A young calf, though, got so scared that it ran directly in front of the auto and only our slow gait, together with a quick turn of the steering wheel prevented a catastrophe.

"I am passionately fond of a *corrida*," remarked Senorita De Lerma, a minute later, "but I do not care to be myself the matador in an automobile. Perhaps we better turn back." But we had arrived within a mile or so from Pando, a picturesque village, and, all of us being rather hungry, it was decided to push on. We reached the *fonda* of the village a few minutes later, where the car was immediately surrounded by crowds of natives. It was Sunday, and, although the host of the inn could not possibly have figured on unexpected guests, we were soon served with a native dinner, consisting of *cossido* (boiled beef and pork, garnished with cabbage, potatoes, sweet *patates*, slices of pumpkin, and *garbanzos*) and cold *mulita*. The latter is a dish, the taste for which does not need much cultivation, if one can overcome the repugnance it causes at first to those who never have seen and tasted it before. *Mulita* is the native name of the armadillo of natural history, the little South American animal which carries its armor on its back and is thus protected against its enemies, except men, who close up its holes and then catch it running. The *mulita* is roasted in its iron-hard shell and served with it. It is the view of the animal lying on its back complete with head and tail that at first tends to turn the stomach of a *gringo*, but if once you have tasted its tender, juicy meat, which has the flavor of roast pork or goose, you are bound to like it.

After dinner we visited the little church and had some fun with the dark-skinned, black-eyed and pretty country girls, who innocently expressed their admiration for the new kind of vehicle. Some of them indicated that they would like to have a ride, and we packed a load into the car, taking them around the plaza. This did not prove a good policy, for the whole crowd now clamored for a turn around the square, and, to escape their importunities, we had to start on our way back.

We reached Montevideo after several more incidents similar to those related further above, and with slightly different experiences from those gained on American country roads.

MARYLAND MAY GRANT RECIPROCITY.

BALTIMORE, Md., Oct. 5.—Numerous suggestions for controlling autos in this State were brought out at the conference of the Maryland Automobile Commission with Governor Crothers. One of the principal subjects discussed was that in reference to licenses of owners from other States who bring their cars into Maryland. Col. Sherlock Swann argued that it was unfair to make an automobile owner from outside of Maryland who came into this State with his machine for a few days pay as much for a license as the man who has the use of the State roads the entire year. All the members of the commission and the Governor agreed on this matter.

Walter B. Brooks then recommended that a 20-day period could be granted to outsiders with automobiles for their stay in Maryland without a license, and the commission decided to make this recommendation. The commission also recommended the alloting of licenses so that a man who took a license out in September of the current year would not have to pay as much as the man who waits until January to procure a license.

The placing of signboards throughout the State was also advocated. On the question of taxing autos Governor Corthers said he wanted to tax machines up to the neck, but not so high as to impose a hardship upon the owners. The Governor declared all revenues should be used in the interest of good roads.

NEWS FROM SOME ACTIVE CLUB CENTERS

BUFFALO CLUB DOING MUCH GOOD WORK.

BUFFALO, Oct. 12.—The Automobile Club of Buffalo still continues to grow in a way which will keep the rival clubs on the jump to equal its membership. When September ended the rolls showed 1,390 names on the list with 37 more waiting to be acted upon. The most notable achievment of the club as recorded for September was the final completion of arrangements with the Canadian authorities whereby any member of the Automobile Club of Buffalo may enter Canada, at any point on the Niagara Frontier, on presentation of his membership ticket, free of any bond. The customs official will make out a duplicate card and hand one to the tourist, good for a three days' stay in Canada.

The club committee on road signs has continued its good work, and the route to Lockport and Niagara Falls, via Pekin, has been re-marked, and danger signs placed where required. The new signs for the road between Fredonia and Jamestown, via Cassadaga, have arrived and will be erected before the middle of the month. The club has been troubled in their work of placing road signs by people who have maliciously torn them down or defaced them, and has made a standing offer of $50 reward for information leading to the arrest of such persons.

WHAT ONE CONNECTICUT CLUB IS DOING.

HARTFORD, CONN., Oct. 12.—The recently organized Automobile Club of Willimantic is a live body, as is evident from the activities of the club of late. For instance, an effective sign-posting campaign has been inaugurated, and the good and bad spots will be indicated as the case may be. A special meeting of the club was held recently and action was taken regarding the betterment of the city streets. A club run is slated for the near future, and also a game dinner at some favorite resort to be decided later. It was voted to purchase a score of A. A. A. radiator emblems, which will be placed on the cars of members as soon as received. A strenuous season is anticipated, and, as Secretary Lincoln expresses it, "in the spring we are going to try to do some other good things which will attract attention.

MINNEAPOLIS CLUB WILL BUILD A HILL.

MINNEAPOLIS, Oct. 5.—Members of the Minneapolis Automobile Club are all enthused over the proposed plan to erect, to order, a permanent hill on the club property at Bloomington, for hill climbing contests. The plan has been talked for a couple of weeks, and the proposition of financing the deal will be taken up before the directors of the club at the next meeting.

As planned the hill would be half a mile long and having a grade varying from 10 to 24 per cent. The course would be laid out along the Minnesota Bottoms directly in front of the clubhouse, so that the races could be watched from start to finish from the porches of the clubhouse or from grandstands to be erected on the spacious lawns. It is thought sandstone block will be used to assure permanency of construction and identical conditions year after year.

The building of a hill "to order," so to speak, has not been done, it is believed, by any other club in America, and the members of the Minneapolis Club are all anxious that the honor of being first should fall to this club. Consequently, with all this interest it is very likely that on Saturday, July 3 next, the hill will be the scene of a contest which will attract national attention.

Chairman J. deM. Thompson of A. A. A. Racing Board and Vanderbilt Cup Commission at Chateau des Beaux Arts, Huntington, L. I.

A. C. A. PROVIDES FOR NEW MEMBERSHIP.

NEW YORK, Oct. 12.—Two new classes of membership have been established by the board of governors of the Automobile Club of America. First the bars were let down to women, and second, a clubroom membership was established. Women have formerly only been allowed in the ladies' rooms under the stairs. By the action they are to have all the privileges of ordinary members, except that they cannot vote or hold office, nor may they use the restaurant and assembly room. Hopes are held out that the proposed extension of the clubhouse over the recently purchased property on Fifty-fifth street will provide them with better facilities later.

The clubroom membership is limited to 100 and can be secured for $25 a year without payment of any initiation fee.

FIRST OF THE MOTORWAYS IS OPENED.

An epoch in motor-driven land transportation is marked by the opening of the Long Island Motor Parkway, a race course only incidentally and not constructed exclusively for high speed competition, as is the generally erroneous impression. First of many motorways for the use of automobiles is the Long Island road, and therein William K. Vanderbilt, Jr., has placed to his credit something which logically should come from a family whose members for three generations have figured in the history of transportation. If man is to get the full worth of the latest form of individual transport, he must supply a road whereon he can take advantage of its time-saving possibilities. All other arteries of travel must be avoided, including the highway on which the horse will continue for a longer period to plod its weary way; the dangers of railroad crossings at grade must be obliterated and the rights of the pedestrian cannot be overlooked, for while many will use the automobile, a still greater number may never be so fortunate. 'Tis a clear and open road that the automobile requires, and, given such, man will enjoy and employ his new means of progress to its fullest reasonable extent; not a few will go beyond the limits of prudence—and, frequently, pay the penalty.

When its plans are entirely consummated, the Long Island motorway will supply an uninterrupted route across the island which, owing to its proximity to the metropolis, its destined to be the home of millions with business and social interests in New York City. Some day the State will supply such motorways—for the ultimate form of all highway traffic is certain to be of the motor-propelled sort—but until that time arrives the owner of the automobile will not object to paying for the boon of an "open road" that is such in reality. The assured enormous population of Long Island is a guarantee of the ultimate financial success of its motorway, but those who have made it possible are not counting upon any substantial immediate return from their investment.

When automobiling will have attained some years to its being, and the events of its past will necessitate the telling so that the new generation can inform itself of that which is history, the chapter on the first of the motorways will make known to what great degree one William K. Vanderbilt, Junior, first prominent because of a racing cup bearing his name, added more permanently to his outoing fame by being the moving and responsible factor in the building of the first road in the world for the daily use of the automobile, which undertaking created an example that was soon followed by many such highways throughout the country, thereby aiding materialy in the growth of a great industry which carried with it far reaching effects.

* * *

PRESENT STATUS OF CLUTCH DESIGN.

Doubtless the weakest part of the design of early cars was to be found in the clutch, and many constructors instead of attempting to overcome the defects of the then standard type, the leather-faced cone, cast about for something entirely different. The result has been the development of a number of types, all of which appear to have proven equally successful when properly designed and constructed for the work to be done, the lack of which summed up the defects of early attempts. Time has shown that it was not the principle so much as the manner of its application.

Despite the predictions of those who found its use a difficult matter of practice in earlier years, the plain conical type has not been superseded by something of later growth, but is as much in evidence on high-priced cars today as it ever has been. It combines the manifest advantages of simplicity, light weight, low initial cost, and ease of repair, and while improvements in design have done much to perpetuate it, the adoption of cork as a friction material, either directly on the metal, or as a supplement to the usual leather facing, has been a factor of great importance in its retention. The multiple disc clutch, which is probably favored by a greater number of designers than any one other type, with the exception of the cone, represents a close approach to the ideal, for all designers are seeking a clutch that may be slipped under heavy loads without damage to itself, besides which it has the great advantage of a low inertia factor, not to mention its extreme compactness and the fact that it is self-contained and generously lubricated. Aside from these two types, which appear to be about equally favored, there are several modifications of band clutches which have been developed to a high degree of efficiency and reliability, and it is worthy of remark that the use of cork has influenced the development of these types, as well as of the disc clutch, where the number of plates employed is comparatively small.

A. A. A. IN QUARTERLY SESSION TAKES IMPORTANT ACTION

IF present plans materialize, and the American manufacturers of commercial vehicles come forward with a plenteous entry, there will be a notable first contest next Spring for the Powell Evans $2,000 trophy for commercial vehicles. This trophy, donated by Mr. Evans, who is president of the Automobile Club of Philadelphia, was formally accepted at the quarterly meeting of tbe Board of Directors of the American Automobile Association, beld in New York City, Friday, October 9, with First Vice-President Lewis R. Speare, of Boston, presiding, in the absence of President William H. Hotchkiss, of Buffalo, who was unable to attend.

For the greater convenience of the association's membership at large, it was decided that the offices of the Touring Board should be removed to New York City in the near future and its work carried on from the general headquarters of the organization, at 437 Fifth avenue. Powell Evans was named as chairman of wbat hereafter will be known as the Touring, Information, and Maps Board, and Frank B. Hower, president of the Automobile Club of Buffalo, who has been chairman of the Touring Board, will become chairman of the Contests Board, which will succeed the Technical Board, and have charge of all contests other than racing and speed events, same to include all touring, technical, endurance and economy contests, as well as hill climbs.

The Racing Board, as heretofore, will continue in charge of speed contests.

Various recommendations of President Hotchkiss were adopted, including an enlargement of the national board of directors, so that every club throughout the country will have a member on the board.

R. D. Inman, of Portland, Ore., was elected a director to represent the Portland Automoble Club. A long list of individual members was also passed upon, and action was taken providing that any individual member whose application is filed after this date will be extended membership privileges covering the fiscal year ending December 1, 1909.

President Hotchkiss was authorized to appoint a committee of five to represent the A. A. A. on the National Conservation Commission, at the suggestion of Gifford Pinchot, chairman of this government body.

The Executive Committee having previously referred to President Hotchkiss and Secretary Elliott the solution of the California situation, their recommendation was that provision be made for two State bodies in a commonwealth of such great geographical extent, and this plan was adopted.

The advisability of issuing a monthly or quarterly bulletin will come up for consideration at the next meeting.

The offer of the Show Committee of the American Motor Car Manufacturers' Association to allot space to the A. A. A. at the Grand Central Palace exhibition in New York City, was accepted. It was also decided to hold a general meeting of the association at the time of this show and again during the Madison Square Garden show in January. Application will be made to the Trunk Line Association for reduced railroad rates during the weeks of these shows. Adjournment was to October 23.

TWENTY AND PERHAPS MORE FOR THE VANDERBILT CUP

AS the entry list for the Vanderbilt Cup race, which is to be beld on the Long Island Motor Parkway course on the 24th, now stands, there are twenty entries in all, representing America, Germany, France and Italy, and there appears to be good reason to believe that there may be further entries in the fortnight still intervening. Of the total number now in hand, tbirteen are American cars, consisting of three Thomas cars, two Locomobiles, two Knox representatives, two Mathesons, and one each of the Chadwick, Acme, Mora and B. L. M. makes. Tbe seven foreign cars are the three Mercedes, a Brasier, an Isotta, a Hotchkiss and a Renault.

Up to the present, all but six of the drivers have been selected. Salzman will pilot one of the Thomas cars, the other two still being without drivers, while Robertson is to have charge of a Locomobile, but his running mate for the other car of the same make is still to be chosen. The Knox entries will be handled by Basle and Bourque, and the two Mathesons will have as pilots, Chevrolet of former track fame, and J. B. Ryall. There is no driver as yet for the Mora. Willie Haupt will handle the Great Chadwick "six," while Strang has been nominated for the Renault and Patsche is to pilot the Acme entry. Of the Mercedes team, two are to be handled by professionals. W. K. Vanderbilt, Jr.'s car being piloted by Luttgen, while Stricker will have the Graves entry. Foxhall Keene will drive his own car as usual.

It is rumored that Montague Roberts will be put at the wheel of one of the added Thomas cars. Kilpatrick seems a likely pilot for the Hotchkiss, in view of the fact that he has been identified with the efforts of that make this season in straightaway and 24-hour contests. Although no announcement of the final choice of driver for the second Locomobile, Jim Florida was given a try-out in the Philadelphia race of last Saturday.

Joseph Tracy has concluded a contract with C. W. Matheson to look after the Matheson camp. Tracy will pitch the Matheson camp at Gifford's. Stricker was formerly a demonstrator for the late Alexander Fisher, of New York, when he was the importer of the Rochet-Schneider. Strang gives Stricker's instructions credit for most of his success as a driver.

Lytle's high average of 64 miles an hour, made in the Isotta last Saturday, has shown what can be done over the new course, and much in the way of record-breaking is to be expected of the Vanderbilt race. Lytle's performance has also created a strong speed craze among autoists generally, and the demand for permission to use the Parkway stretch has been so great that it has been thrown open from 8 A. M. to 6 P. M. daily, the fee being $2 for that time, but no night driving will be permitted until after the Vanderbilt. Motorcycle riders who have had an opportunity to try the course are anxious to have a big motorcycle event.

In the Vanderbilt race itself, six of the American cars will carry Diamond tire equipment, and to add further zest to the race, the Diamond Rubber Company has offered $1,000 in prizes for winning cars shod with its tires. This sum is divided into a first prize of $500, the second, third and fourth to finish receiving $250, $150 and $100 respectively. The tires will be mounted on Diamond demountable rims and will be inflated ready for use.

The entry list and drivers as complete up to October 12 are given out as follows:

Car.	Country.	Entrant.	Driver.
Acme	America	Cordner & Flinn	Patschke
B.L.M.	America	Thos. Williams	Williams
Chadwick	America	Chadwick Eng'g Wks.	Haupt
Knox	America	Knox Auto Co.	Basle
Knox	America	Knox Auto Co.	Bourque
Locomobile	America	Locomobile Co.	Roberteon
Locomobile	America	Locomobile Co.	———
Matheson	America	Matheson Co.	Chevrolet
Matheson	America	Matheson Co.	Ryall
Mora	America	Mora Co.	———
Thomas	America	E. R. Thomas Co.	Salzmann
Thomas	America	E. R. Thomas Co.	———
Thomas	America	E. R. Thomae Co.	———
Brasier	France	H. Payne Whitney	———
Hotchkiss	France	Hotchkiss Import Co.	———
Isotta	Italy	C. V. Brokaw	Lytle
Mercedes	Germany	W. K. Vanderbilt, Jr.	Luttgen
Mercedes	Germany	Robert Graves	Stricker
Mercedes	Germany	Foxhall Keene	Keene
Renault	France	Paul Lacroix	Strang

HOW A NEW JERSEY COUNTY GAVE AN AUTOING LESSON

MADISON, N. J., Oct. 10.—New Jersey automobilists turned out in great numbers for the big automobile tour "Around the World" in Morris County, Saturday, and despite the threatening weather the affair was a success. It is estimated that $3,000 was realized from the sale of tickets, fancy articles, etc., which amount would certainly have been doubled but for the cold, threatening weather during the afternoon, and the rain that brought things to a stop fully two hours earlier at night.

The tour was arranged for the benefit of the Y. M. C. A. of Morristown and Madison and the Girls' Club and Boys' Brigade of Chatham. Each passenger was charged $1 for the entire tour of fifteen miles, which included stop-over privileges at the different stations. These included the beautiful estate of James M. Gifford at Chatham, which was decorated as Peking, China; the home of C. F. Wheeler in Main Street, Chatham, representing Washington; the home of James H. McGraw, Prospect Street, Madison, which was attired to represent Madrid; the home of C. M. Decker at Convent, which represented Yokohama, Japan; F. C. Blanchard's large estate in the Woodland Road, near Chatham, which was decorated to represent Berlin, and L. B. Tompkins' home at Morristown, which place represented Constantinople, Turkey. Each of these places was gorgeously decorated in the native colors they represented, and were all the more attractive by the costumes of those in charge of the various booths. Aside from the different stations as above described, the tourists were given an opportunity of shopping at the Y. M. C. A. buildings at Madison and Morristown. Among the many attractions at the latter place were the two Arabian horses of Homer Davenport, which were on exhibition at the Tompkins estate. The route of the tour carried the sightseer past the historic Washington headquarters in Washington Avenue, Morristown, one of the chief objects of interest.

The affair was arranged by a group of prominent residents of the three New Jersey towns, who were organized as the International Touring Company. These included James H. McGraw, president; Willard W. Cutler, Thomas W. Cauldwell, Homer Davenport, Alfred Evans, James A. Webb, H. S. Heitkamp, and Charles M. Lum, vice-presidents; Edward P. Holden, Jr., secretary; Edward D. Conklin, treasurer; Herbert Strong, general manager; W. Reginald Baker, superintendent; A. B. Leuder and H. B. Stopford, division superintendents; Melvin Jackson, general ticket agent; H. D. Ogden, general passenger agent; Emory N. Faulks, general freight agent; Carrol B. Merritt, general advertising manager; Theodore B. Morris, general publicity agent; F. A. Trowbridge, master mechanic, and W. F. Day, Jr., courier-in-chief.

Aside from it being a huge charitable entertainment, the affair was a gigantic automobile carnival as well, and the society folk of Morris County were out in force. Never before was there such a large procession of automobiles assembled in that section, and the beautiful macadam roads connecting the three towns resembled a Vanderbilt Cup course. More than one hundred machines were loaned for the day, and these were kept on the go from 2 o'clock in the afternoon until 7 o'clock at night, when it began to rain. Many of the nearby residents kept their cars in service until late in the evening, and the tourists were given an opportunity of reaching their respective starting points. There was much congestion during the afternoon, and many more cars could have been pressed into service, but the crowd was very well taken care of.

Not a single accident marred the event in any way, and it was voted a grand success. Aside from this, it demonstrated the true merits of the modern automobile, and will be the means, no doubt, of relieving much prejudice that has heretofore existed. The people of Morris county, hundreds of whom took advantage of the fifteen-mile run, were shown the need of better legislation. As an example, a large percentage of the residents of the towns in that fashionable section are devoted to their horses and use the roads extensively, and the immense number of automobiles traveling along the fifteen-mile course was the means of demonstrating the necessity of lights on all vehicles, while the roads themselves need more lights.

ONE THOUSAND AUTOMOBILES IN LINE.

Probably one of the most notable features of the Deep Waterways convention in Chicago last week was the outing given the 5,000 delegates in automobiles supplied by Chicago owners for use of the Association of Commerce. When the 1,000 machines were lined up they extended over six miles of pavements, representing a total valuation of over $3,000,000.

HARTFORD AUTOISTS HELP OPEN A CONNECTICUT BRIDGE

HARTFORD, CONN., Oct. 11.—There has just been successfully concluded a three days' celebration of the formal dedication of the new stone bridge across the Connecticut River. The structure is said to be one of the finest stone bridges in the world. In connection with the celebration there was an industrial procession. The Hartford Rubber Works Company, the Electric Vehicle Company, the Pope Manufacturing Company, the Whitney Manufacturing Company—in fact, all concerns identified in one way or another through their product with the automobile industry—were represented. Of the good accomplished by the demonstration there is not the slightest doubt. As celebrations go, it was typically New England. The automobile parade in the evening was a gorgeous affair.

Cars and commercial vehicles were gorgeous in their embellishment. One that is particularly deserving of mention is a light electric truck used by a local Swedish society, by means of which was shown a model of a Viking ship, and so gracefully did the mimic craft spin over the ground that the mode of propulsion remained a mystery to the uninitiated. Of the commercial vehicle section proper, the Hartford Rubber Works had a very unique float. The big electric truck of the company was decorated in keeping with the event, and the sides bore mammoth trade-marks in electric lights in the form of winged tires. The Pope Manufacturing Company was present with the big Waverly electric truck, on which was carried a 1909 model. The Electric Vehicle Company used the Riker electric truck, above which was an illuminated electric sign, and two old-time models were carried. The touring and runabout section was notable for many reasons. The seasons of the year were portrayed by various cars and decorated accordingly. President W. F. Fuller, of the Automobile Club of Hartford, was marshal of the procession in the Pierce-Arrow "six."

In all, about 600 cars participated, about three times as many as had been expected, and 50 motorcycles. So long was the procession that long after the start of it had reached the center of the city the finish had not passed that point to the turn, about three miles distant.

The Automobile Club of Hartford after the parade entertained the visiting autoists at the Allyn House. During the smoker there was formulated the Aero Club of Hartford, of which H. P. Maxim was chosen president, C. H. Gillette secretary, and F. W. Dart treasurer. Charles F. Glidden was the guest of the Automobile Club of Hartford, and the formation of the Aero Club is practically due to his visit.

FIRST SPACE ALLOTMENT OF A. M. C. M. A. SHOW.

Last week the American Motor Car Manufacturers' Association held a three days' session for the purpose of allotting space for the "Great White Auto Show" which opens on New Year's Eve. Because of the large demand for space—more than 70 different American and foreign makers applying to be assigned floor room, besides the accessory manufacturers—those in charge found that they would not be able to give each exhibitor the amount first thought possible, a reduction of 30 per cent. being necessary for vehicle makers while the producers of parts were taken care of as expected. The following were among those lucky enough to draw space in the court of honor:

Reo, Stoddard-Dayton, Mitchell, Ford, Maxwell, Premier, Mercedes and Panhard. The other cars assigned spaces included the DeDion, Delahaye, Clement, DeDietrich, DeLaunay, Fiat, C. G. V., Isotta, Renault, Lancia, Hotchkiss, Jackson, National, Overland, Marion, Mora, Atlas, Buckeye, DeLuxe, Pennsylvania, American, Brush, Marmon, Simplex, Motorcar, Gacth, Gearless, Kiblinger, Holsman, Welch, Abendroth, Moline, St. Louis, Austin, Moon, Chadwick, York, Oakland, Midland, Acme, Regal, Coates, Anderson, Benner, McCue, Wayne Works, Middleby, Speedwell, Lanc, Kissell, Schacht, Omar, Claude E. Cox, Gyroscope, Page, Cameron, Sultan and Cleveland.

Among the commercial vehicles are Rapid, Grabowsky, Abendroth, Mack, Bristol, Lansden, Hart-Kraft, Gram-Logan, American Truck, Pittsburg, Reliance, and DeDion.

CARTERCAR BUILDERS EXPAND GREATLY.

DETROIT, Oct. 12.—The Motorcar Company, builders of the friction driven Cartercar, has filed papers for an increase in the capitalization of the concern to $350,000, as well as for a change of title, the corporation being known in future as the Cartercar Company. The large plant of the Pontiac Spring & Wagon Works, Pontiac, Mich., has been acquired, and the work of transferring the machinery and stock now in the old Motorcar company's factory, at Twenty-first and Baker streets, Detroit, will be undertaken at once, and it is expected that the new plant will be working full blast on the 1909 product within 30 days. The new plant is excellently situated, being located at the junction of the Detroit, Grand Haven & Milwaukee and the Michigan Airline railroads. The buildings are brick and concrete, five stories high, and cover about two acres of ground.

The leading Cartercar model for 1909 will be of the runabout type, and is designed to list at $1,000; it will be known as Model K, and its specifications are such that there is little doubt of its popularity during the coming season. The Model G roadster will be continued for another season, with a few improvements here and there, while an entirely new touring car, known as Model H, will be put out to succeed this year's Model A. The Cartercar Company will also continue to build the Pontiac, which is a high-wheeler listing at $675.

IMPORTS SHOW INCREASE FOR AUGUST.

During the month of August the foreign manufacturers seem to have done an increasing business in this country as shown by the Government reports for that month. In the month of August, 1907, only 69 machines valued at $229,704 were imported, while for the same month, this year, 179 cars with a valuation of $280,970 were shipped here. These figures show that the price per car was a great deal lower this year than last, being about half, which is probably due to the fact that some of the smaller foreign chassis is becoming more popular in this country and also the fact that a large number of the taxicab chassis come from France.

Houston, Tex.—The Southern Motor Car Company has purchased the lease, machinery, tools, garage and good-will of the Empire State Motor Company, and in the future will be located in the former garage of that concern at Texas avenue and Caroline street.

PACKARD LOSES BIANCHI IN JERSEY DAWN.

If the man responsible for the New Jersey auto law, one Frelinghuysen by name, was really in earnest in his endeavor to prevent speeding by its misguided provisions, he must have had a powerful bad dream in the wee sma' hours of Sunday last, for the peace of that Sabbath morn in Jersey was rent by two automobiles keeping as far above the legal speed limit as their motors and their drivers' nerve would let them. They were a Bianchi and a Packard, at least that is the order in which they got away, the former crossing the imaginary line near West End station, a part of Long Branch, at 5:52 A. M., the Packard leaving five minutes later. When they came in the order was reversed, the Packard leading the way by a considerably greater margin than favored it at the start. Henry Weisel and M. R. Rothschild, two New York brokers, were the offenders, and the run-off was the result of many wagers as to the ability of the cars. Mr. Rothschild drove his Packard, while the Bianchi was entrusted to a chauffeur, and none of the essentials of a first-class event, such as timers, starter and referees, was missing. The course was 60 miles through a number of Jersey's seashore villages, the distance being covered by the Packard in 1:10:30,1-5, despite the drizzle.

ONE MAKER'S HUNTING TRIP.

Henry Ford recently took a ten-day hunting trip, the greater part of his traveling being done in a Model T Ford car. As the first of these cars happened to be ready about the time Mr. Ford wished to start on his trip he found it very convenient to give one of them this extra trying out in Northern Wisconsin. The trip was made via Chicago to Milwaukee, and to Iron Mountain, where several days were spent, then back again to Detroit, a total of 1,357 miles as shown by the speedometer. During the whole trip the magneto alone was depended upon, as no battery was taken at all. The following record of gasoline and oil consumption for the trip is rather interesting:

From	To	Miles.	Gasoline.	Oil.
Detroit	Chicago	345	15	5
Chicago	Milwaukee	118	6 1-2	1-2
Milwaukee		30	1 1-2	1-2
Milwaukee	Iron Mountain	285	14	3
Iron Mountain		25	1	1-2
Iron Mountain	Milwaukee	292	17	1
Milwaukee	Grand Haven	Boat	..	..
Grand Haven	Detroit	262	13	1
		1357	67	11 1-2

The average for trip was 20 miles per gallon of gasoline and 85 miles per gallon of oil. From this table it can be figured that the cost per mile per passenger was a little over ⅛ of a cent and if depreciation, etc., is added, less than ⅜ of a cent per mile per passenger.

Mr. and Mrs. Clarence Mackay, Who Are Renault Users.

Original Winton That Was Shown in Philadelphia Parade.

ORIGINAL WINTON IN QUAKER CITY PARADE.

In the industrial parade during Founders' Week at Philadelphia, October 7, one of the floats carried what is claimed to be the first gasoline automobile made and sold in America. This is a single-cylinder Winton phaeton, bought by Robert Allison, of Port Carbon, Pa., on April 1, 1898. For several years the car has been in the museum at the Winton factory. It appeared in exactly the same condition as when Mr. Allison drove it last; the old single-tube tires are rather the worse for wear, but the mechanism is still in working order. In fact, before the car was shipped, Mr. Winton started the motor and drove it around the factory yard.

MINNEAPOLIS TO HAVE AN AUTO ROW.

MINNEAPOLIS, MINN., Oct. 12.—Recent developments among the local agencies indicate that Minneapolis will have a "Motor Row" worthy of the name. Five of the large companies have closed deals involving heavy investments for sites and elaborate buildings on Hennepin avenue, the main thoroughfare of the downtown district, and building operations have been started. The five concerns thus far in the movement are the Stoddard-Dayton; the Minnesota Motor Sales Company, handling the "E-M-F," Studebaker, and Babcock electrics; the Maxwell-Briscoe combination; the Pence Auto Company, handling the Stevens and Buick; and the local branch of the Winton Motor Carriage Company. These are among the largest agencies in the Twin Cities, and such a general movement to a new locality carries weight.

The Stoddard-Dayton location, next to the corner of Hennepin avenue and Ninth street, is regarded as an ideal one. Its new garage building, to cost about $20,000, has been started.

Across the street will be the Minnesota Motor Sales Company's location, and here also a very showy and complete building will be erected to cost about $20,000.

The Pence Auto Company have acquired a site formerly owned by the Mutual Life Insurance Company, where the foundation was put in several years ago for a 21-story building. This project was abandoned, however, so in taking over the site the Pence Company gets a good start on its new six-story building.

The local branch of the Winton Company is having a garage and sales building erected on North Eighth street within a short distance of Hennepin avenue. This building will be so constructed that additional stories may be added in the future.

The Maxwell-Briscoe Company has also located in this same vicinity and plans are being drawn up for a $20,000 building, which will also be used as the Northwestern distributing plant.

Many dealers in accessories and other auto dealers have watched the progress of events, and there are several deals now on foot leading to the location in this neighborhood.

CHANGING THE DARRACQ TAXICAB.

PARIS, Oct. 1.—Several modifications have been made in the Darracq taxicabs familiar to New Yorkers by reason of their exclusive use by the New York Taxicab Company. The gilled tube radiator across the fore end of the frame has been abolished in favor of a dashboard radiator with thermo-syphon water circulation. The bonnet takes the form that up to the present has been almost exclusively associated with Renault cars.

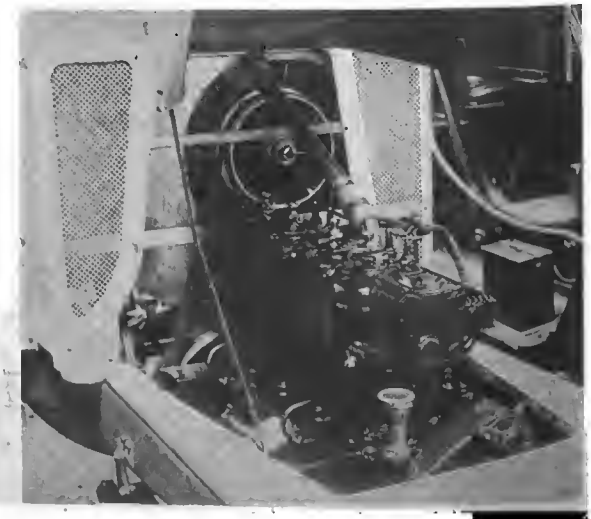
The new radiator consists of a series of circular plain copper tubes, there being twelve tubes in each circle and four or five circles. On the dashboard, and in the center of the inner circle of tubes is a flat blade ventilator driven by a belt direct from the flywheel at one-third increase on the engine speed. The dashboard space left free on each side of the rear of the bonnet does not allow a view of the radiator, as on most dashboard-radiator cars, this being enclosed by sheet metal super-imposed by a perforated plate, the object of the enclosure at this point, of course, being to increase the draught of the fan. The passage of the steering column through the dashboard has not allowed the radiator to be mounted in a central position, but slightly to the left. As no tubes are visible owing to the front covering plate, this peculiarity does not in any way mar the appearance of the car.

Advantage has been taken in the change of cooling arrangements to improve on the lubrication of the engine. On the 1907 taxicabs the flow of oil from the dashboard lubricator was assured by pressure from the exhaust, a system which possessed more simplicity than efficiency. On the new models the Lefebvre lubricator is of the force feed type, being direct driven off the ventilator shaft; the one belt operates fan and lubricator.

There has inevitably been a slight modification of the engine by the abolition of the water pump, but this is really the limit of the changes on the power plant. Transmission and final drive also remain as before, but suspension has been changed, the transverse rear spring being abolished in favor of three-quarter elliptics, a type of suspension which is being more and more generally adopted by European constructors. There has been a strengthening of the steering gear and modifications on the connecting bar to allow of taking up play with greater facility, thus assuring the parallelism of the wheels.

A series of three hundred of the improved models are about to leave the Darracq factory for service in New York and other American cities.

Atlanta, Ga.—Within the next few weeks the new garage being built for the White Company will be ready for occupancy. Their representative, E. W. Gans, will make this the distributing point for the Southern States.



New Thermo-Syphon Radiator Used on Darracq

ONE STORY OF A CLEVELAND RACE MEET.

LEVELAND, Oct. 13.—Dashing and tearing around the track, ling like an alarm of musketry, flying around dangerous ves, yet always holding true to the track, roaring monsters iron and steel, emitting flashes of flame and smoke, kept tators and officials keyed up to a highly nervous strain for days last week.

Vomen shrieked and all but fainted as the daredevil drivers ed life and limb in their mad efforts to be first at the tape! ng men grew sick at heart as the powerful machines seemed med to destruction, and laughed with relief when the cars ped as by a miracle. The whole crowd swayed with the rs as they tore around the turns and held their breath when car or the other gained a slight advantage. Never had such derful work been witnessed upon a race track! All the ers were striving to do their best (?), each wishing to cleave himself a niche in the hall of fame. And what roars went when first one and then the other won during the heartling two days. Oldfield, Christie, Kelsey, and Soules are es that will live forever in the hearts of Cleveland motorists!

---

his was received in THE AUTOMOBILE's mail early Monmorning, and upon wiring our Cleveland correspondent to out what it was all about, it was discovered that the "Nal Circuit Meet" was held in that city last week. No records broken, as the track was not fast on either day.]

NCH AUTOISTS ANNOUNCE SAILING DATES.

RIS, Oct. 8.—Passage has been secured for the French teams g part in the Grand Prix of the A. C. A., at Savannah, on teamship *La Lorraine*, leaving Havre Saturday, October 24. drivers will consist of Szisz, of the Renault team; Duray, ie Dietrich firm, and Rigal and Hautvast, the two Bayardent drivers. Each driver will have his own mechanic, and or two helpers will be taken over. Six racing cars will be ed on the same boat, the Renault firm sending two and rd-Clement three, though racing one and two, respectively. tober 14, Victor Breyer, the European representative of the ican Automobile Association and manager of the first e Grand Prix, will sail from Cherbourg in order to attend anderbilt Cup race and the Savannah event.

is declared by Henry Fournier that two Italas will be ed in the Savannah Grand Prix, one of which will be hanby himself, and the other by Cagno. In the Bologna race ly, Fournier proved himself one of the fastest drivers, and or missing the turn might have been very near the winner.

. KELSEY IN DIFFICULTY WITH HAYNES CO.

VELAND, Oct. 13.—After having made a good showing in ack races here on Friday, and while he was tuning up his at night preparatory to doing still better work the follow-y, Robert G. Kelsey, of New York, the well-known driver, aken into custody by the Cleveland police, charged with a fugitive from justice, the arrest being made by request Chicago police. The warrant was sworn out by the s Automobile Company.

ey will say little, but he is mad clear through, and inhat the Haynes people are taking into the criminal courts which belongs under civil jurisdiction. All day Saturday sts of this city who know Kelsey offered to bail him out, der the charge bail cannot be accepted. Kelsey says he ake things warm for somebody.

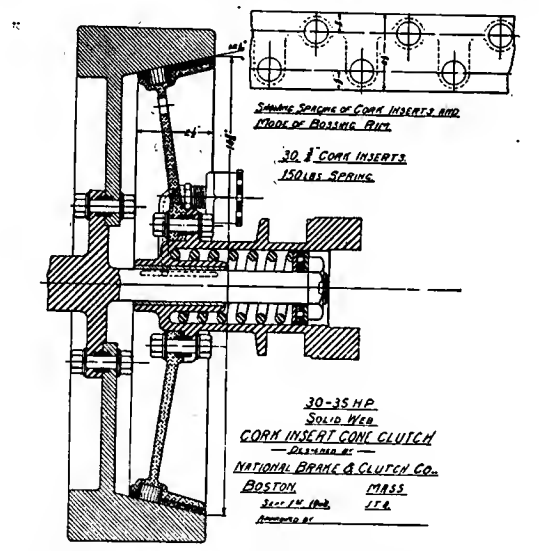
TERNATIONAL ROAD CONGRESS OPENS.

s, Oct. 12.—M. Barthou, the French Minister of public officially welcomed the delegates to the first International Roads Congress, which was formally opened to-day. The es represent 24 different countries.

DRAWINGS OF CORK INSERT CLUTCHES.

Editor THE AUTOMOBILE:

As the demand for cork insert clutches is constantly increasing and as the designers of these clutches have not always the necessary data to bring the best results, our engineer has prepared plans of three clutches of 20-24, 30-35 and 45-50-horsepower, respectively, embodying the results of three years' experience in designing these clutches and indicating the angle and width of face, diameter of



cone, area of cork surface, weight of spring, etc., required to give the best results, and we are forwarding to the automobile manufacturers drawings of these in reduced size and will furnish full-size drawings to engineers or manufacturers (without charge therefor) where they will be of use, and we suggest that the publication of this letter or a statement of its contents may be of value to some engineer or prospective manufacturer who may not otherwise have an opportunity to receive these drawings.

NATIONAL BRAKE & CLUTCH CO.,
LAWRENCE WHITCOMB,
Treasurer.

Boston, Mass.

NEW JERSEY'S BIG CLUB TO CHANGE NAME.

NEWARK, N. J., Oct. 13.—It is very probable the name of the New Jersey Automobile and Motor Club will be changed to the New Jersey Automobile Club at the annual meeting of the organization. At the last meeting of the trustees a resolution to that effect was passed, and the matter was referred to the special committee consisting of Secretary A. B. Massena and Dr. James R. English, which was appointed some time ago to revise the by-laws of the club. The club was originally organized to admit motorcyclists as active members, but the by-laws have since been changed so as to admit only automobile owners, hence the word motor is superfluous. It is not likely that there will be any objection to the change.

The new club house will be formally opened on Thursday evening of this week. A delightful program, which will take the nature of a house warming, has been arranged, and several hundred of the members have notified Secretary Massena of their intention to participate in the festivities.

FORT GEORGE CLIMB ON ELECTION DAY.

The New York Automobile Trade Association has postponed its Fort George hill climb, originally scheduled for next Saturday, to Election Day. It has assurance that the Board of Aldermen ordinance giving the permission will be signed by Mayor McClellan. A previous ordinance of the Board of Aldermen intending to grant permission for the climb had failed to provide for police surveillance or to mention the name of the promoting organization. For this reason Mayor McClellan had vetoed it.

Arthur Lee Trying Out a Four-cylinder Maxwell for the Jericho Sweepstakes.

alisbury Wheel Company's "Annual."
n keeping with its established custom, Salisbury Wheel Company of Jamesn, N. Y., gave its annual three days' ertainment to its customers at the comy's camp at Lake Ctautauqua the latter t of last week, and nothing was left one to make the visitors feel that they had the time of their lives before they through. Among those present were the owing: R. Harry Croninger, Penn Auotor Co., Bryn Mawr, Pa.; Benjamin sco, Maxwell-Brisco Motor Co., Tarryn, N. Y.; B. J. Walker, Erie Malleable n Co., Erie, Pa.; Mr. Harris, Driggsbury Ordnance Co., Sharon, Pa.; W. J. idervoort, Moline Auto Co., Moline, Ill.; A. VanWie, Overland Auto Co., Indipolis, Ind.; H. W. Hayden, Dayton Mo- Car Co., Dayton, O.; W. S. Gorton, ndard Welding Co., Cleveland, O.; H. McDonald, W. H. Vanduesen and J. Edsel, of the E. R. Thomas Co., Buf-; B. B. Covert, Covert Auto Co., Lockt, N. Y.; G. W. Atterbury, Autocar ipment Co., Buffalo, N. Y.; S. E. Babk, Babcock Electric Co., Buffalo, N. Y.; nk Barnett, representing *The Automo-* and *Motor Age;* L. W. Palmer, Jamesn, N. Y.; T. G. Meachem, New Process whide Co., Syracuse, N. Y.; Mr. Grunr, secretary of the Auto Manufacturers' dit Association; Charles Backus, West- Malleable Steel Co., Detroit, and E. Sherman, S. H. Penfield, C. A. Mccheon, C. A. Pickard, E. D. Cook and tcher Goodwin, of the Salisbury Wheel

Why Pierce Transmission Is Changed.
peaking of the change from the prossive gear, operated by a small lever on steering column, to the side-lever oper- selective gear, which will be a feature the Pierce cars for the coming season, announcement from the George N. rce Company, Buffalo, is as follows: uch greater significance than appears at t glance is contained in the change in transmission on all the new model rce-Arrow cars. Heretofore cars of this ke have been equipped with a threeed progressive transmission with the r-shifting lever under the steering wheel. w, however, all five Pierce-Arrow modwill have four forward speeds, and selective type of transmission, while gear-shifting lever will be at the side, and will work in an H double slot. Several reasons have been responsible for the retention of the former type after the selective had been proven a success. Among the more potent of these was the fact that it has been the belief of the George N. Pierce Company that the progressive system, with the lever under the steering wheel, is the simplest and most convenient style for the man not thoroughly up in motoring. In other words, the Pierce company held that, in former years, the general autoing public had not advanced in its knowledge of conditions to a point where the selective type would prove more serviceable than the progressive."

Autoists Combine to Fight Thieves.—The automobile owners in Fort Wayne, Ind., have been troubled to such an extent of late by automobile thieves that they have formed the Fort Wayne Automobile Protective Association. At the first meeting over $500 was subscribed to a fund which should be at the disposal of certain officers of the association to use in the apprehension and conviction of all auto thefts and for the purpose of taking some action against the careless throwing of glass and tacks on the highway. The members also pledged themselves to do all in their power to aid in the crusade against those persons owning automobiles who persist in disregarding all speed regulations to the detriment of all others.

Buys Beaver Engine Plant.—The Filer & Stowell Company, Milwaukee, Wis., has secured control of the Beaver Manufacturing Company, builders of Beaver engines, and will conduct the business in the future, gradually increasing the output to about 25 engines per day. A new four-cylinder, 40-45-horsepower, vertical engine will be added to the line, the same design as the present R. A. type. The Filer & Stowell Company's interest in the Beaver Company furnishes ample capital to do business on a large scale which was a much needed requisite of this rapidly growing business. New buildings are being constructed to take care of the increased output, and over one-half of next year's business has already been contracted for.

How One Company Does It.—A six-day conference for traveling mechanics of the Franklin Manufacturing Company, whose duty it is to instruct and assist Franklin dealers in the proper care of Franklin automobiles, has just closed, and the nine men who cover territories that represent all the United States left for their several quarters. The entire week was taken up in study of the 1909 models and their features augmented with talks given by Chief Engineer John Wilkinson and his staff. One day they took a trial of 225 miles in the 1909 models, and during the journey every man was given an opportunity to drive each of the various 1909 models.

Continentals Out of Smaller Races.—Manager Joseph Gilbert, of the Continental Caoutchouc Company, announces that the numerous races which are being held now have so interfered with the regular business of the company that the company will have to withdraw its support from the racing game, except for the large events.

Cleveland Taxicab Company.—The Cleveland Taxicab Co., with its factory in the old Geneva steamer plant at Geneva, O., will not have its new machines ready until the 1st of January. The factory is busy now, but no completed machines will be ready for some time.

Jones Speedometer.—The Jones Speedometer Company of New Rochelle, N. Y., has been incorporated with a capital stock of $100,000, for the manufacture of instruments, tools, machinery, etc.

Oakland, Pontiac, Mich.—The Oakland Motor Car Company, of Pontiac, has filed a certificate at Lansing, increasing the capital stock of the company from $200,000 to $300,000.

Made Record-Breaking Easy.—Herbert Lytle used Harris oil to lubricate the Isotta he drove to victory in last Saturday's Motor Parkway Sweepstakes.

IN AND ABOUT THE AGENCIES.

Rambler, Kansas City, Mo.—The Rambler Automobile Company has been organized with the following named as incorporators: W. L. Lacy, Estel Scott, George Devol, J. R. Nave and E. G. Anderson, the latter to act in the capacity of general manager. The new concern will handle the Rambler line exclusively and establish branches in this section.

American Locomotive, Chicago.—General Sales Manager James Joyce of the American Locomotive Automobile Company has completed arrangements whereby the Chicago branch will be located in the old Zion Tabernacle, at Twelfth street and Michigan avenue. Benjamin C. Day, who has been with the Winton Company for some time, will be in charge.

Lancia, Boston.—The Hol-Tan Company has decided that a Boston branch would be profitable, and have secured quarters at No. 66 Hereford street, where salesrooms will be opened within a few days. W. M. Hilliard, who has driven for the Hol-Tan Company for some time, will be in charge of the new branch.

Gray & Davis, New York City.—A branch of this well-known concern, which has its factory at Amesbury, Mass., has been opened at 377 West Broadway, near Broome street, the telephone number of which is Spring—2478. William H. Gray is in charge of the branch.

Continentals, New York State.—The Continental Caoutchouc Company, 1788-90 Broadway, New York City, has added one more distributing agent to their long list. The Albany Hardware & Iron Company, Albany, N. Y., will represent this company in the Northeast and middle part of New York State.

ozier.—W. S. M. Mead, Eastern sales ager of the Lozier Motor Car Com- , has established the following new cies: Westcott Garage Company, a; A. C. Foss, South Norwalk, Port- er, Stamford and Greenwich; C. S. om, Albany, and Newburg Auto Shop, burg, N. Y.

anklin, Utica, N. Y.—The Franklin r Company has been organized with s in the Commercial Travelers' build- to handle the Franklin cars in Utica. Gardinier, the former manager of . H. Childs & Company automobile ess, bas been elected president and al manager.

ne, Savannah, Ga.—The Graham nobile Company, of No. 14 Bryan , has taken the Georgia agency for the and some adjoining territory. This my has for its president and treasurer es Graham, with Thomas Halligan as ary and general manager.

rry Autocab Company, New York —The Cherry Autocab Company, of York has been incorporated to carry garage and sell and rent automobiles, capital of $25,000. Incorporators: rd Stein, L. L. Dobbin and A. S. t, all of New York City.

Consumer's Auto Supply Com- Pittsburg.—With C. D. Mandille, rmer manager of the automobile de- nt of Kauffmann's store, as presi- nd H. G. Kimmich as treasurer. This n has opened up for business in the block.

h, Philippine Islands.—The Brush ut Company, of Detroit, Mich., re- made a shipment of samples of its t to H. R. Cooper & Company, Philippine Islands. This latter firm present the Brush interests in that y through 1909.

and, Indianapolis.—Charles R. formerly of the Olds Company, anized the Independent Automobile y, which will be located at 214 East ork street, Indianapolis. The new ll carry a complete line of Oakland

on, Utica, N. Y.—Cbarles H. & Company have arranged to act as ting agents for the Jackson cars in ork State outside of New York id will establish branch agencies wns where the trade warrants it.

ell, Indiana.—The agency for the cars in St. Joseph and Elkhart , has been taken by George F. Eb- who will have his headquarters at Second street, Mishawka, Ind.

, Philadelphia.—The Acme cars aken care of by the Theobold Mo- Company, 608 North Broad street. mpany has H. P. Childs for its t, and J. B. Theobold for manager.

Kar, New York City.—The Ap- otor Car Company, in addition to ge on West Eightieth street, has salesroom at 2250 Broadway, for of Kissel Kars.

r Pumps, Boston.—S. F. Heath ny, 288 Columbus avenue, Boston, n appointed New England distrib- the well known Spencer power ps.

New York City.—Charles A. s removed the Moon Agency to in the old Smith & Mabley build- roadway and Fifty-sixth street.

Blanchard, New York City, has incorporated with capital stock , for the manufacture of auto- nd supplies.

Midland Motor Car Company, Kansas City.—This concern has removed to its new quarters at No. 1608 Grand avenue.

Michelin, Philadelphia.—A branch of the Michelin Company has been opened at No. 320 Broad street by H. D. Benners.

PERSONAL TRADE MENTION.

"Pete" Estey, Studebaker Publicist.—Following the announcement to the effect that E. L. Pelletier, of the E-M-F Company, will handle the entire advertising of the Studebaker Automobile Company, as well as the E-M-F campaign, comes the further announcement that Mr. Pelletier has engaged as assistant advertising manager for the Studebaker, F. L. ("Pete") Estey, who for several years has been attached to the automobile department of the Chicago *Inter-Ocean*. Mr. Estey is known to almost every newspaper man in any way interested in the development of the automobile industry. Mr. Pelletier plans to superintend all Studebaker publicity and advertising from the Detroit office, and Mr. Estey will follow up stunts and contests, reporting them in detail.

James F. Patton, superintendent of the F. B. Stearns Co., Cleveland, has resigned to go into the repair business for himself in that city. Patton is very well known in the trade, having been connected with the Stearns company for the past five years. He was presented with a diamond pin and Morris chair upon leaving the factory.

George B. Levy, who has been secretary and sales manager for C. A. Coey & Company, of Chicago, for two years, is leaving that company to go into business for himself in a concern which will be known as the Standard Automobile Supply Company, No. 1428 Michigan avenue, Chicago.

W. F. Reynolds, Southwestern representative for the H. H. Franklin Mfg. Company, finds business in general throughout his territory to be in a most prosperous condition. Automobile dealers are enthusiastic over the outlook.

Frank Lowry, a former Indianapolis newspaper man, well known in the East and Middle West, has signed with the Moline Automobile Company, of East Moline, Ill., to handle publicity and advertising.

F. C. Morgan has been appointed sales manager of the American Automart, 1619 Broadway, New York City, where extensive improvements are being made for the coming winter.

B. F. Blaney has resigned as Boston representative of the Selden car.

GUY VAUGHAN JOINS BENEDICKS

Guy Vaughan, manager of the mechanical department of Wyckoff, Church & Partridge, the Stearns New York agents, well-known as a crack race driver, was married Thursday, October 8, at New Rochelle, N. Y., to Miss Helen Knapp. When the newly married pair started on their wedding journey, which will comprise an automobile trip through the Berkshires and New England, they were pursued in cars by fun-loving tormentors, but managed to outfoot their pursuers.

DEATH OF VETERAN WRITER.

L. C. Boardman, former automobile editor of the Chicago *American*, died in that city on October 7. Mr. Boardman was a graduate from the ranks of cycle newspaperdom, in which he was rated as a pioneer, his bicycle page in the New York *Recorder* bearing a national reputation. He leaves a widow, herself a journalist in the same lines as those of her late husband.

BUSINESS DIFFICULTIES.

The Association of Motor Car Dealers, New York City, which has offices in the *Times* Building, New York City, has made an assignment to John H. Winans. The concern, which was incorporated for $10,000 in March, 1907, has assets consisting of cash in banks, $1,603; accounts, $2,100, and office furniture with the value not given.

A. L. A. M. 1909 HANDBOOK.

The work of publishing the sixth annual "Hand Book of Gasoline Automobiles" is well advanced, and the book will be issued before many weeks. This hand book is the hall mark of the Association of Licensed Automobile Manufacturers, and this year it will be larger and even more attractive in appearance than it has been in the five previous editions.

There was held last week at the rooms of the A. L. A. M. a meeting of the committee which deserves the credit for the merit of the book in the past. Among those present were Thomas Henderson, of the Winton Motor Carriage Company; William E. Metzger, of the Everett-Metzger-Flanders Company; Charles Clifton, of the George N. Pierce Company, and E. P. Chalfant, assistant manager of the A. L. A. M.

L. XIX NEW YORK—THURSDAY, OCTOBER 22, 1908—CHICAGO No. 17

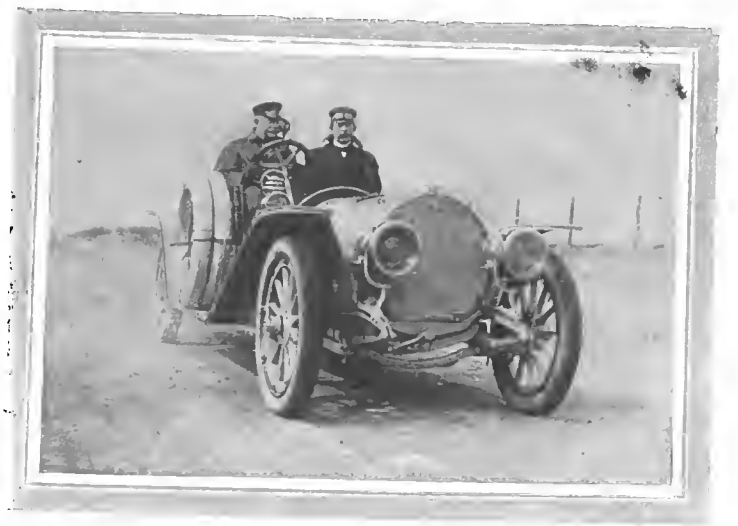
THE AUTOMOBILE

ALL IS READY FOR FOURTH VANDERBILT RACE

GINNING at daylight next Saturday morning will be run the fourth race for the William K. Vanderbilt, Jr., Cup eleven laps of a 23.45 mile course, aggregating 257.983

Seven European and twelve American cars have drawn ig numbers. They embrace for the most part cars of ished records, and, in the matter of pilots, proven long- ce performers. In their number and the variety of their they are adequately representative of the fastest and enduring brands of the foreign and domestic product. of them were contenders in the third Vanderbilt race.

ne of the two iobiles, Joseph scored the fast- of that contest, e Thomas, which Salzman is to with Le Blon at ieel, finished a- f all the Ameri- rs in that mem- struggle. The es, entered by Graves, was by Jenatzy in 6 race, and the iss, to be driven patrick, is said duplicate of the Elliot F. Shep- d. A second of 06 Vanderbilt es will have at el Howard W. Baltimore ama- e third Buffalo



Chairman Thompson of Cup Commission and Major Crowley of Irish Brigade.

e is the Thomas used by Louis Strang in the Grand Prix year. Foxhall P. Keene will again drive his former s. Two other contenders were built for the last Vander- ocomobile as an emergency substitute for Tracy's car, in t of an accident in practice, and a B. L. M. not com- time to competc.

f the new candidates for cup honors among the cars eady won distinction—the Isotta by its succession of in the Savannah, Briarcliff, Lowell and Sweepstakes; x by finishing second in the Lowell contest, and the evolving third at Savannah and second at Philadelphia. ting as will be the meeting of these seasoned racers ddition of much new speed blood, it will not compare excitement of the competition among the coterie of illful, and competent drivers of long distance racing in try has developed in the past two years. Public attention is to a considerable extent centered on a trio of drivers, whose performances during the season just closing and successes in very recent races have placed them at the head of the American speed squadron. Herbert Lytle, who was a Pope-Toledo pilot of former Vanderbilt races, is to man the Isotta he drove to victory in the Motor Parkway Sweepstakes. Louis Strang, who was at the wheel of the Isotta at Savannah, Briarcliff and Lowell, is to drive for Paul LaCroix, the Renault that put up a new world's record for 100 miles on Ormond beach. Strang's stirring struggle in a stock car Renault in the last 24-hour race at Brighton Beach, in which he alternated in the lead with the Isotta until his car was put out of the running by an accident, is fresh in the public mind, followed as it was by his close pursuit of Lytle in the Sweepstakes, also in a 40-45 horsepower stock car. The third member of the rival trio, George Robertson, will pilot the Locomobile he drove to victory at Philadelphia, following his capture of the last Brighton Beach 24-hour race in a Simplex.

William K. Vanderbilt, Jr., has secured Walter Luttgen, a veteran of the Long Island classic, to drive his Mercedes. At the wheel of Mr. Graves' Mercedes will be Emil Stricker, who has been a Porthos pilot in the Grand Prix contests. The Hotchkiss will be guided by H. J. Kilpatrick, who was the driver of the Shepard Hotchkiss when it scored the world's straightaway mile road record at Jamaica last spring.

Willie Haupt, J. B. Ryall, Cyrus Patschke, and William Bourque. drivers of no little experience in long-distance road and track contests in this country, will be found respectively in the seats of the Chadwick, Matheson, Acme, and Knox cup candidates. The pilotage of the Le Blon Thomas has been entrusted to George Salzman, who has won fame in endurance runs and road record trials, and the fate of the new Matheson racer to Louis Chevrolet, who several years ago scored not a few track records for Major Miller in a Fiat.

Leon Pouget, Brasier; Howard Gill, Thomas, and Thomas

Willie Haupt in the Six-cylinder Chadwick, Which Is Rated at 90-Horsepower.

illiams, B. L. M., are practically unknown to road racing, is also Alfred Dennison, who has been substituted for Charles isle as the pilot of the big Knox.

Jim Florida, who has been driving the second Locomobile in actice, may be the final pilot of this car. Wednesday it became own that the Grand Prix Thomas would not be able to meet e weight restrictions of the contest, and, therefore, its entry om the race was withdrawn.

Previous Races for the Cup.

The first Vanderbilt Cup race was run in 1904. It was run ith controls. Its net distance was 284.4 miles. The race re-lted in a memorable duel between George Heath, Panhard, id Albert Clement, Clement-Bayard, the former winning by a arrow margin in 5:26:45 net, an average of 52.2 miles per hour. is fastest lap averaged 67.2 miles. The fastest round of the ce showed an average of 70.8 miles per hour, which was ored by Teste in a Panhard.

Controls were abolished the next year, the course being 283 iles. Hemery in a Darracq evolved as the winner in 4:36:08. eorge Heath piloting a Panhard was second. Joseph Tracy in a Locomobile was third, being the first American combination of car and driver to officially finish in an international road race. Hemery averaged 61.49 for the race and 68.42 for his fastest lap. Lancia, Fiat, however, scored the swiftest round with an average of 72.88 miles per hour.

The third race for the cup took place in 1906 over a 297-mile course, and resulted in another victory for the Darracq, Wagner winning in 4:50:10, with an average of 61.43 for the race and 65.11 for his fastest lap. The best round of the race, however, was scored by Joe Tracy in a Locomobile, at an average rate of 67.66 miles per hour.

Effectual Guarding of the Course.

The crowd at the 1906 event was enormous and almost uncontrollable. But one fatality to spectators, however, resulted, though there were several onlookers injured. The result was that the A. A. A. Racing Board voted not to hold any further contest for the cup until it could be adequately guarded by militia as well as police, or to be run over a protected course. The wisdom of the A. A. A.'s policy in this particular has been very generally recognized, so that at practically all of the big road races, and even at hill climbs the promoters have succeeded in providing militia to guard the course.

The A. A. A. in 1907 failed to secure legislative action or the sanction of the Governor to use State troops and the race was not run. It is interesting to note that those who howled the loudest at the postponement, have been foremost in casting obstacles in the way of the present contest being run. The building of the Motor Parkway, however, solved the problem for this year. Although but a portion of it has been completed, it is over that section of the course that the chief danger would arise and that is protected from end to end by a high wire fence. The militia protection will be afforded by Thomas Francis Meahers' Irish Brigade, a corps made up largely of veterans, who saw service in the Spanish war, and had its first service in the war of the Secession. In its ranks are many trained athletes. They will co-operate with the Pinkerton men, and Nassau county deputies, the soldiers being detailed more particularly at turns and in places where the greatest crowds are sure to congregate.

The Acme Six-cylinder, Rated at 60-Horsepower, to Be Driven by Patschke.

That Dream of an Autoway.

That nine miles of cement parkway will be included in the 23.45-mile circuit, over which this year's Vanderbilt Cup race will be run, marks a new era in automobile road racing, the entire fulfillment of which will come with the completion of the entire 60 miles stretch of the Long Island Motor Parkway next season. The great American classic next year will be run over a speedway exclusively constructed for automobile traffic without speed limitations.

Almost since the birth of the motor car there has been a dream of such an automobile roadway. For nearly a decade there had appeared in print "fairy tales" of the projected building of such a great speedway at the gates of the metropolis. It was for the American Automobile Association, however, to take the initiative step toward the realization of this

. On October 6, two days before the last Vanderbilt Cup he directors of the national body passed resolutions direct- e president of the association to appoint "a committee of to consider various propositions to conduct automobile on especially reserved rights of way, and, in view of the ility of conducting the elimination race for 1907, to in- the committee to at once carefully consider such propo- as may be submitted before referring them to the full of Directors."

liam K. Vanderbilt, Jr., Jefferson deMont Thompson, . R. Pardington, the committee appointed by President kiss, considered propositions made for speedways in the of New York, New Jersey, and Connecticut. The com- did not let grass grow under their feet, for on October ere was a conference of wealthy Long Island property s at the Lawyers' Club, the outcome of which was the ay proposition. Assurances of financial support came so tly, not only from Long Island, but from automobile

George Robertson and No. 16 Locomobile, a Likely Combination—Designer A. L. Riker in the Background on the Right.

as well, that on December 18, 1906, the Long Island Parkway was incorporated with a capital of $2,500,000. months of persistent hustling and diplomatic effort to right of way followed. Success was finally attained. ne 6 of the present year work was begun with appro- naugural ceremonies near Central Park station, and rapid icient constructive work resulted in the present stretch

being completed in ample time for the preliminary practice for the novel combination sweepstakes, run over the full Vanderbilt course on October 11, resulting in the winner of the principal race proving the speed qualities of the new course by setting up a new American road record, supplanting by a big margin the former figures established first by Heath, then by Hemery, and closely approached by Wagner in the last contest.

Cars Are Practicing Daily.

Following the drawing of the position numbers last week daylight practice over the course began. A large majority of the entrants were easily able to show laps running from 21 to 23 minutes. But one accident marred the tryouts. Emil Stricker on Sunday last was rounding the Jericho turn at high speed in Robert Graves' Mercedes, when a tire blew out. The car dashed through a fence, throwing out Stricker and his mechanic, Arthur Murray. Both members of the crew were taken to the Nassau County Hospital at Mineola. Stricker, who was badly bruised, is confident of being able to drive in the race. Murray, however, was more seriously injured, having sustained concussion of the brain. The car escaped with a broken rim and hood, and was soon repaired and will start Saturday.

The weighing-in of the cars took place at Gray's scales at Garden City yesterday. Several cars were over weight and found it necessary to reduce in order to make 2,644.8 pounds.

DETAILS OF THE NINETEEN CARS ENTERED FOR THE FOURTH RACE FOR THE VANDERBILT CUP.

The Two Matheson Candidates for Cup Honors.

Luttgen and Mate Don't Look Like Daredevils.

WHAT FRANCE WANTS FOR 1909 INTERNATIONAL RULES

PARIS, Oct. 15.—France wants a maximum bore of 140 millimeters (5.51 inches) for a four-cylinder engine, and a minimum weight of 1,984 pounds as the essential conditions of the 1909 Grand Prix and of all international races held throughout the world. It was a foregone conclusion that the 155 millimeter bore and 1,100 kilos minimum weight would be abandoned after this year, for the 1908 season has proved that cars are too fast for tires to stand the strain.

The Sporting Commission's regulations will be submitted to the international conference of recognized clubs, to be held in Paris, October 19, and will doubtless come in for severe criticism, Germany, Italy, and England being in favor of a reduction to 130 or even 120 millimeters for the four-cylinder engines. As the French delegates have instructions to hold out for the 5 1-2-inch limit, the fight is likely to be a keen one. The argument of the other members of the congress is that with 140 millimeters and the reduced weight cars will be as fast as this year, and there will be danger of the tire falsifying the mechanical results. When the present rule was formulated at Ostend, Germany was in favor of 135 millimeters, while France held out for 160. In a spirit of compromise France came down to 155, the belief then being that the reduction would produce a car slightly lower than the square motors of 170 and 180 millimeters bore, and as Henry Brasier expressed it, "It would be valuable to slightly reduce the bore each year and still maintain the same average speed." The possibilities of long-stroke engines were not sufficiently realized by the experts, as is proved by the fact that contrary to general expectations, more power was obtained with the restricted bores than with the unlimited engines. With a bore of 130 millimeters an average long-distance speed of nearly 70 miles an hour is possible on a good course, and at such a rate of travel tires are near their limits of resistance. It is probable France will have to come down to 155 millimeters.

The question of the changing of wheels will come up for discussion at the meeting, with the probable result that this departure from standard racing practice will be allowed. The question was brought forward prominently last year, when S. F. Edge asked to be allowed to use Rudge-Whitworth dismountable wheels. His request was refused, and he thereupon commenced an active campaign that was doubtless more profitable than winning the Grand Prix. As the last Grand Prix was largely lost to the French by the failure of rims and tires, and as the English device allows a reduction in weight of 140 pounds per car, it is likely that France will have no objection to the change.

For voiturettes it has been decided to increase the bore where two and four-cylinders are employed. For one-lungers 100 millimeters remains as the maximum bore. For two-cylinder cars the limit of bore has been carried from 78 to 80 millimeters, and for four-cylinder engines the maximum bore will be 65 in place of 62 millimeters. This, however, will not affect the international conference, the French voiturette race being considered a national affair.

What the International Committee Will Recommend.

PARIS, Oct. 20.—At a meeting to-day of the racing committee of the International Association of Recognized Automobile Clubs it was decided to recommend that the rules for high speed racing in 1909 limit the cars to a minimum weight of 900 kilograms (1,984 pounds) with a cylinder bore of 133 millimeters (5.23 inches) limitations.

Robert Gravee's Mercedes After Its Sunday An

USE OF THE FARM TRACTOR IN FRANCE

By W. F. BRADLEY.

RGES, France, Oct. 15.—Central France, the most highly eveloped agricultural district of the world, has been se- is the spot for the first International Agricultural Motor ion. But though this is a country where the land is made uce its maximum, it is not one in which mechanical aids to ture have been most highly developed. Thus, when the ition for mechanical means of plowing was commenced, ee machines which lined up in front of the judges were ively from Chicago, Bedfordshire, England, and Paris. n the International Harvester Company's machines are old articles in France, the American tractor is a new fea- nd as such was watched with considerable interest. The Ivel machine is one which has made itself known in the s and foreign countries during the last three or four years, French Castelin is practically a new comer. The method ation on both the American and British appliance was for stroke. First connection with the transmission gear is a leather-faced cone clutch, the gear being reduced twice before drive is finally taken to rear axle by a single chain. Though water cooled, the engine has no radiator, the necessary amount of water being carried in a large tank at the rear of the machine and circulation assured by thermo-syphon. The road wheels are all metallic, the two rear ones taking the drive, and the single front one being steering. When used across country, transverse ribs are attached to the face of each of the rear wheels, being detached when running on macadam roads.

The Castelin tractor has a single-cylinder vertical De Dion motor as its power producer, the bore and stroke being 4 3-10 x 5 1-10 inches. The engine is water cooled, has automatic inlet, mechanical exhaust, and ignition by storage batteries. Power is transmitted to the front wheels by means of a low-reducing gear, a countershaft and side chains. The rear wheels are

ree machines were put practical tests on a d divided off into equal e award of the judges ade on the speed with e work is done, is reg- nd economy of opera- o report has yet been t it is evident that the prize distribution will be between sher and the Yankee only.

ternational Harvester Company's tractor consists of a linder horizontal engine, mounted on a four-wheel car- he engine is of the long-stroke stationary type, with two wheels, and a modified form of water tank forward, the leaving the engine being sprayed through a fine wire een, then collected in a tank below. The valves are in the exhaust only being mechanically operated, and the ntrolled by a governor operating on the exhaust lift.

el machine is a compact three wheeler, having as its nt a double opposed engine of 6 x 6 inches bore and

Castelin Tractor Coping with a Wire Cable.

steering, with control by tiller. For stationary work, the drive is taken in a similar manner from a separate countershaft bearing small pinions to the drumshaft by means of side chains. When required for plowing, the tractor is immobilized by dropping down a powerful strut and fixing in the ground a couple of posts between which is laid a chain to carry the pulley, around which the cable runs. The practical operation is the simple one of setting the winding drums in operation and drawing the plow through the ground, one man remaining in charge of it, while another occupies himself with the engine.

Although interesting comparisons could be made by watching the three machines at work together in one field, it was impossible to arrive at very definite conclusions without detail figures of cost of operation in each case. The French tractor, having the lowest power and the lowest initial cost, would at first sight appear to be the most economical, but, as the tests showed on rough ground, the cable had difficulty in performing what was accomplished easily by the two hauling tractors.

After the plowing tests the tractors were invited to operate a reaper, which task was very successfully accomplished by both

he Ivel and the International Harvester machine; the Castelin id not take part in this. Finally, by means of belt connection, he three tractors were put to stationary engine work, driving arious types of farm machines.

The feature of the exhibition held for one week in the town f Bourges was the number of stationary engines of various ypes operating threshers, grinding mills, choppers, churns, saws, tc. Single cylinder machines of both horizontal and vertical ype were in the immense majority, and varied in power from 1 o 30 horsepower. Gasoline was practically the only fuel used, he alcohol section, which it was expected would be important, failing to attract entries; steam was unrepresented, with the exception of one English tractor. Single cylinder engines, vertical type, with mechanically operated valves and high-tension magneto, mounted on a light carriage with two wheels, were shown in numbers, generally linked up with a water pump, or provided ith pulley for belt connection to various machinery. It is in this direction that the greatest opening for the introduction of internal combustion motors to agriculture in France is likely to be found.

During the exhibition lectures were given by experts on the application of motors to farming, comparative costs supplied, and general pioneer work undertaken.

GOOD RESULTS OBTAINED WITH VARIOUS FUELS IN FRENCH TEST

PARIS, Oct. 15.—Gasoline is not the only fuel on which automobiles can be run economically, as is proved by the taxicab and delivery vehicle competition which has just taken place in the neighborhood of Paris. The competitors were given a difficult course in the vicinity of the capital to be covered each day, giving a daily distance of 76 miles. Sixty per cent. of the course was over rought paving stones such as the environs of Paris alone can provide; 30 per cent. was over bad macadam; the rest of the course was good going. Hills, with a maximum grade of 12 per cent., tested the climbing abilities of the cars.

Gasoline, White Spirit, carburated alcohol, benzol, and any fuel the competitor desired had to be used on five successive days. Before each fuel test the vehicles went over the course with the fuel they were to use on the following day, but without any other control than that of a time schedule. This allowed them to make the necessary adjustments and tune up the carbureter for the fuel test, all the work being done by the driver only, no mechanics being allowed on the cars.

The annexed table tells the story of the competition, the chief feature of which was the good results obtained on various fuels and the small amount of fuel used. There were no mechanical defects except on a Cottereau, which overheated, was supplied too suddenly with cold water, and cracked a water jacket. The vehicles engaged consisted of a couple of single-cylinder De Dions of 100 by 120 bore and stroke, one having an hotel omnibus body and the other a closed delivery van, both loaded with sacks of sand; Unic had a four-cylinder 12-horsepower hotel 'bus and a similar chassis with a delivery body; Cottereau had a four-cylinder cab, 85 by 105 bore and stroke; and a three-cylinder engine, which failed to finish; Vinot had a 80 by 110 four-cylinder taxicab; Bayard-Clement had a couple of two-cylinder chassis, 85 by 110 bore and stroke, developing 10-horsepower, the one carrying a taxicab body, the other a closed delivery van. In each case the full load was carried in the shape of ballast, and interior dimensions were demanded for all delivery vehicles. The following table shows the comparative consumptions with the four different fuels employed. It is worth noting that the circuit was the same for each test, the roads always dry, and the weather fine from beginning to end.

	Vehicle.	Cylinders.	Bore and Stroke.	H. P.	Total Weight, Pounds.	Fuel Consumed, 76 miles. Gasoline, 680 deg. gallons.	White Spirit, gals.	Alcohol, 50% gals.	Benzol, gals.
1	De Dion - Bouton 'bus	1	100x120	8-9	4,890	3.04	2.63	3.30	2.60
2	Unic 'bus	4	76x119	12-14	4,386	2.63	2.48	2.92	2.17
3	Cottereau taxicab	4	85x106	16	3,638	3.62	3.16	3.47	3.22
4	Vinot-Deguingand taxicab	4	80x110	12-16	3,119	2.56	2.62	2.89	2.20
5	Unic taxicab	4	76x110	12-14	2,976	2.29	2.17	3.01	1.84
6	Bayard-Clement taxicab	2	86x120	10	2,436	2.05	1.79	2.17	1.55
7	Demeester delivery van	4	72x80	10	2,050	2.99	2.18	2.43	1.70
10	Unic delivery van	4	76x110	12-14	4,250	2.40	2.39	2.69	2.03
11	De Dion - Bouton delivery van	1	100x120	8-9	5,522	4.04	3.62	3.60	2.86
12	Cottereau delivery van	3	85x105	10	4,772	6.87	Retired.		
13	Bayard - Clement delivery van	2	85x120	10	3,042	1.95	1.98	2.21	1.81

With one exception the carbureters were not changed for the tests with different fuels, the drivers merely changing the floats and in some cases putting in different nozzles. There was considerable difficulty in starting up cold on alcohol, but once going the engines ran well and seemed to develop as much power as with the other fuels. The slight difference in time at the various controls shows that the engines were not disadvantaged by the frequent changes of fuel. Final awards will be made on a price basis only, the car in each class having the lowest expenditure for fuel being the winner. Owing to the small number of entries in the various classes the competitors are grouped in the accompanying table.

JACOB'S LADDER TO HAVE AN IMPROVED ROADWAY

BOSTON, Oct. 19.—One of the most important contracts for State road, in the opinion of autoists, ever given out by the Massachusetts Highway Commission, was that which has been awarded to Joseph F. McCormick, of East Providence, for constructing a road around the famous Jacob's Ladder grade in the Berkshires. The contract involves an expenditure of $37,352, and by its terms requires that the new road shall be completed by August 15, 1909. To do the work within the time limit the contractor will have to use a double force all the time. He has already begun getting the materials on the ground and intends to make a big start this fall.

Jacob's Ladder, with a maximum grade of 16 per cent., lies on the most direct route between Lenox, Pittsfield and the western towns and Springfield and other places in the central and eastern part of the State. It can only be avoided by a long detour over poor roads and ever since automobiles came into use has been one of the most troublesome grades in the State. Incidentally Jacob's Ladder has been a gold mine for the farmers in the neighborhood, as they have earned good pay hauling automobiles over the hill.

The new State road will have a maximum grade of 6.36 per cent. It will start at the end of the State road in Chester, and for some distance will be built on the site of the present highway, three new concrete bridges being a part of the contract. After a stretch of new road on the old site, the route will swing northward, paralleling the present road, but with easier grades. It will then return to the present right of way and follow it to near the base of Jacob's Ladder. From there another detour will be made of about 6,500 feet around the hill. The contract calls for the construction of 3 1-2 miles of road.

C. G. Bleasdale and His Maxwell, a Perfect Scorer.

Perfect Score Thomas Light "Six," Geo. Sperry Driving.

FOUR ADJUDGED PERFECT IN CLEVELAND TEST

VELAND, Oct. 17.—The most successful endurance con-
st ever held under the auspices and direction of the
nd Automobile Club came to a close in this city last
with four cars out of the original nine starters having
cores.

committee in charge had some mighty hard points to

At first brush the Maxwell four-cylinder roadster,
by C. G. Bleasdale, was given the only perfect score,
er three hours' consideration, and having had a number of
ficials, entrants, and drivers on the carpet, the Garford
car driven by E. E. Ernest, C. S. Carris' Franklin, and
v Thomas light six, handled by George Sperry, were de-
to have perfect records. This decision was not arrived
l very late last night, the chairman of the contest com-
W. F. Bonnell, being called from his home to reconsider
inal decision.

1 the tbird day's work had been finished, and D. E. Bee-
f Chicago, was examining the cars, it was found that the
of the Garford touring car, A. R. Davis, secretary of
ford company, had been told that if he would enter at
e hour, it being the afternoon before the start, his car
ıot have to take the brake test. His machine was brand
ken off the salesroom floor, and was admittedly not in
n for such a contest. With the knowledge that he
ıot be penalized for loose brakes, his car went in, com-
ɔugh perfectly. Driver Ernest, when ordered to take
ɛe test, refused to do so, and 'phoned for Davis to
the examination. Upon arrival Davis told his side of
r, but the technical examiners could not remit the test,
is then stood for it, the car going too far on the foot test. Davis later appeared before the committee and clearly stated his side of the case, also declining to protest the decision in case his car was penalized, as he did not wish to make trouble for the local club. Under the circumstances, and upon the recommendation of Mr. Beecroft, the brake test was not counted at all. This allowed the Garford and Thomas to have perfect scores, the latter car having originally suffered a penalization of five points on the hand brake test.

The Franklin's case was very queer. It appeared that the car ran many miles out the right way owing to wrong confetti marking, and, being compelled to "beat it" at a fast clip, ran out of oil. This gave the car a penalty of twelve points on the second day. After the contest was over, however, it was found that many observers had been lax, and that oil had been used in other cars in violation of the rules without having been noted. The drivers afterwards admitted this, claiming that, owing to the lateness of their entry, they had not studied the rules carefully. It would have been impossible to penalize all cars, owing to lack of clear information, and had the Franklin penalty stood, it would have been manifestly unjust to that one car. Consequently Chairman Bonnell gave the Franklin a clean score under the circumstances.

The run was a most severe one for several reasons. In the first place the schedule called for a straight twenty miles an hour, with an average daily distance of 157 miles, and four controls each day, the object of which will be explained later. This meant that the cars could keep ahead of their schedule but a few miles, for whatever they gained would be quickly lost, as they had to wait to allow the schedules to catch up. Combine this with a twenty mile average on the last portion of the

S. Carris "Beating It" in Clean Score Franklin.

E. E. Ernest's Garford "30"—Another Clean Scorer.

day's running, which took the cars through the streets of Cleveland when the traffic was the densest, and one can gain an idea of the speed required.

The perfect scores commenced to go by the board the first day, when a loosened screw in the coil box of the Stoddard-Dayton caused trouble. Driver Moore broke both his bonnet and battery box seals before locating the trouble in the coil, and suffered a penalty of 53 points. All the other machines ran into the control that night with nary a penalty, but early the next day the severe pace commenced to tell.

The first car to get into trouble was the steady little Chalmers "30." The motor died, and from its actions Driver Stickney went after his spark plugs, changing them, the trouble then being found to be dead batteries. Being unable to locate an extra set in the car, Stickney telephoned ahead to Chagrin Falls, and after waiting a half hour, one of the passengers found some tucked away under one of the seats. Stickney hurriedly wired them up, and a few minutes later was tearing along. Incidentally, he passed the relief car from Chagrin Falls at such a fast clip that he was not recognized. His car was penalized, of course, for breaking the seals and work done, but he might

Oldfield Carrying the Officials in the Stearns "Six."

have made up his lost running time had it not been for the fact that the short controls prevented. As it was, he drew 209 points.

Then Wedler's Garford roadster, the only amateur entry, found trouble, the radiator springing a leak which necessitated refilling twice. This penalized him 14 points.

Johnson's Jackson was the next to suffer, breaking a main bearing just out of Youngstown. This put the car down and out, and at the end of the second day left the Garford touring car, Thomas light six, Maxwell and Chalmers "40" fighting for honors with clean scores, the Franklin having drawn the penalty which was afterward removed.

Early the next morning the Chalmers "40" went out, the fan breaking and tearing a hole in the radiator. Driver Emerson could have continued without the fan, but he was unable to plug the radiator leak. Nothing else was penalized that day, the cars coming through to the examination in splendid shape, surprising even Examiner Beecroft. In fact, after carefully looking over every machine as to wheels, axles, springs, motors, clutches, fans, bearings, differentials, mufflers, steering mechanism, transmissions, ignition systems, etc., only one lone car was found to have the slightest trouble, the amateur Garford, which, by the way, was entered at the last moment without preparation, having the front wheels sprung one-quarter of an inch. Everything else was ship-shape throughout on all the machines, and the condition of the springs after the many hard humps was universally commended. Not one had sagged a quarter of an inch.

Then came the committee meeting Friday night, and the changing of penalties, as noted above.

The only trouble with the entire event was the fact that it was really gotten up at the last moment, six of the nine entries coming in the day before the start. Then, too, the confetti was sprinkled by a man who knew nothing about such work, and was carried in a competing car. Aside from this, the contest was handled in a brisk, snappy manner, and plans are even now being made to repeat it in the future.

The event just finished introduces to the trade a new figure—W. B. Bonnell, next president of the Cleveland Automobile Club. This was the first event ever handled by Mr. Bonnell, and although handicapped by the work of some of the club officials, he swung the contest with admirable vigor.

To D. E. Beecroft, vice-chairman of the Technical Board of the A. A. A., is due the credit of making the contest a real event when everything looked black. At the conclusion of his work Friday evening he was given a real ovation by the crowd in the club rooms, and a motion to ask him to assist him in the next run brought a hearty assenting vote.

Of secondary consideration in the minds of the contestants, but of considerable import to the Automobile Club officers, was the "speaking" feature of this run. An effort, quite successful, was made to interest the farmers in this contest, and to bring home to them in a forcible manner the best way to secure good roads throughout the State. Barney Oldfield, with his six-cylinder Stearns racer, carried a number of well-known Cleveland citizens along, who made addresses at the short controls to the farmers who had previously been notified of their coming. At these controls every car was held for ten minutes, and as a result, by the time the speaking commenced anywhere from three to nine cars, dust covered and showing the strains of travel, were lined up. A crowd was naturally drawn, then the speakers introduced the subject of good roads, the best way to secure appropriations for this purpose, etc. But, be it related, the speaker generally made one mistake, for Barney Oldfield was introduced, and the fact that he had his racing car along was mentioned. Whereupon Barney seemed to rivet the greater share of the farmers' attention upon himself and car.

Following is the summary of the run:

No.	Car.	Driver.	H.P.	Cyls.	Score.
8.	Maxwell	C. G. Bleasdale	28	4	1,000
6.	Thomas	George Sperry	40	6	1,000
7.	Garford	E. E. Ernest	30	4	1,000
3.	Franklin	C. S. Carris	28	4	1,000
2.	Garford	C. R. Wedler	30	4	946
1.	Stoddard-Dayton	H. S. Moore	45	4	922
12.	Chalmers-Detroit 30	J. H. Stickney	30	4	791
4.	Chalmers-Detroit 40	Sam Emerson	40	4	—
9.	Jackson	Grant Johnson	40	4	—

PHILADELPHIA NOW WANTS ANNUAL RACE.

PHILADELPHIA, Oct. 19.—Since the phenomenal success scored by the Quaker City Motor Club with its 200-mile Founders' Week race little else has been talked of here. Some of the more enthusiastic of the Quakers are even talking of putting on a 24-hour race in November, but there is a division of sentiment over this scheme, and it will likely be abandoned for the reason that November weather is not suitable for an all-night grind and that a profitable "gate" is improbable.

The city fathers are so enamored of the thrilling wind-up the Q. C. M. C. furnished them for the Founders' Week program that when sounded on a proposition to make such a race an annual fixture in Fairmount Park every man-Jack of them acquiesced and said that it would be a good thing to advertise the city.

The "consistency cup" for regularity of running throughout the contest was awarded to the Acme, driven by Patshke, which was the cup for second place.

Last Wednesday a committee of inspection from the Fairmount Park Commission went over the course and found that in two working days it had been restored to its former condition; in fact, it is in better shape, for while many other of the park roads were inordinately dusty as a result of the dry weather, those roads forming the 7.8 mile course were clean and smooth. The $2,500 bond put up by the club to guarantee repairs will be returned less than $500 shy. The $25,000 bond put up to make the city safe, in event of suits instituted for injuries from accidents, will be returned intact.

THE UTILITY OF AUTOMOBILE CLUTCHES

By THOS. J. FAY, E. E., President Society of Automobile Engineers

THERE are very few clutches of the type involving the expanding hand, and, as a rule, they are not so good as to warrant their use. The mechanism required to move the shoes is complex, and centrifugal force is bound to play an undesirable part. If the shoes are of manganese bronze with cork inserts, as in Fig. 3, the surfaces will hold to the work to a marvelous extent, provided the mechanism is such as to serve for the clutching function to an adequate degree. Cone clutches of the conventional sort were once so prevalent as to lead one to the conclusion that they were the permanent standard. Fortunately, there is no such thing as a standard, excepting in so far as principles must hold throughout the designs.

Fig. 3—Shoe of expanding band clutch, fitted with cork inserts.

The earlier cone clutches were faced with leather, riveted onto the periphery, without any means of providing for evenness of contact. The leather thus did not serve the purpose well, and the next important improvement was hy way of flat steel springs under the leather facing, with a view of pressing the leather into contact at numerous points around the entire circumference. This scheme made cone clutches possihle. For a time after this innovation it looked as if cone clutches were the acme of perfection, hut the adoption of cork inserts protruding through the leather rendered the clutches far more stable and lasting. Cork inserts, if well placed and of sufficient surface, work very well indeed without any leather.

Fig. 4 shows a leather-faced cone clutch, with the cork inserts located around the periphery. The same figure will serve to illustrate this particular type in general, since the only difference lies in the application of the cork, in which event the section of the aluminum spider must he provided with inwardly projecting "bosses" in which the holes may he drilled to take the corks. With the cork inserts there is a slight increase of weight if leather is used as well. If, on the other hand, cork alone is used, the weight is lower for the cork insert cone clutch than it is if the leather facing is used. Leather is heavy, especially if we consider that the requirement for the average cone clutch is not far from 75 cuhic inches. It must also he borne in mind that the leather is at the extreme radius, where weight is the greatest detriment. Through the courtesy of the National Brake and Clutch Company I am enabled to offer some data of the performance of cork in clutch service, which data was procured by that company for the purpose of aiding designers in the process of applying cork to the class of work of the subject and for brake shoes, such as are used in automohile and other work.

Fig. 5 gives the pressure and equivalent friction of cork on steel without luhrication, the cork heing inserted in cast iron discs or plated of sufficient thickness. As will be seen by inspecting the chart, the frictional resistance for one pair of plates without the cork inserts is about 80 pounds, if some 500 pounds pressure is applied. It will also be seen that 20 corks in a similar plate, under the same pressure, just ahout doubles the friction. This is equal to saying that the clutch ability is double. The same curve or chart shows a variety of possihilities, using various numbers of inserts, and it shows that the resistance is not in direct proportion to the number of inserts, considering a given pressure. The exact test as reported by Prof. John R. Nichols, of Harvard, is worthy of note, in that it gives more exact values than can be taken from a chart, although the latter affords a bird's-eye view of the whole performance, which would be lost in a tabulation.

550	83	113	132	149	156	...

The corks, one inch in diameter in holes (put in wet under pressure), were in plates of cast-iron five inches wide by ten inches long, and were smoothed down to a uniform hearing and pressed against a clean dry steel surface; the cast-iron plates were ¾ inch thick. The resistance offered was that of the plates with cork inserts considering the loads in pounds as given at a low speed. The consequences of a high velocity was not here taken into account. This is not necessary to consider in ascertaining the coefficient of friction, although it may be well to keep the difference in the mind's eye, against the time when the conditions to be met, in any given case, may introduce a variahle.

The question will naturally arise as to how much of the friction is due to cork, as against other materials, such as dissimilar metals in contact with each other. This is a matter that can he disposed of if tests of the dissimilar metals are taken. The following tabulation will show the results of metal to metal contact, under the same conditions and by the same authority, made at the same time and place. The test then should hear a close relation. It will, of course, be well to keep before the mind's eye, the fact that the tests are associated with the accuracy, naturally expected, of a laboratory of some pretensions.

450	72.9	68	63
500	81	75	70
550	89	83	77

The tests as above indicated for metal to metal contact were made on plates ten inches long hy five inches wide, with polished

urfaces, free of any foreign substance. The area of the plates hen was $10 \times 5 = 50$ sq. in., and for 500 pounds the pressure er square inch was:

$$P = \frac{500}{50} = 10 = \text{pounds per square inch.}$$

It is plain to be seen that differences in metals influence the riction, but it is equally plain that cork increases the friction ery greatly indeed, in comparison with metal to metal, no natter what metals are used. If the coefficient of friction is aken as the resistance divided by the pressure, then the coeffiient for bronze on cast iron may be taken as:

$$f = \frac{70}{500} = 0.14.$$

On the other hand, if cork inserts are used in the bronze lates on a basis of 20 per cent. cork surface, the coefficient of riction will be:

$$f = \frac{131}{500} = 0.262.$$

These relative results are of no great value, because they do ıot take into account practical conditions that cannot be avoided. In practice, oil will furnish a slippery surface in the case of the netal to metal contact, and unless the pressure is very high the slippery surface cannot be eliminated. On the other hand, the ork coefficient of friction does not seem to be affected by the ɔil film to any marked degree, and high pressures are not required to get rid of the slippery surface. The life of the members will be far longer if the pressure is low, and with cork the life can ɔe prolonged because the pressure *can be low*, even if oil does

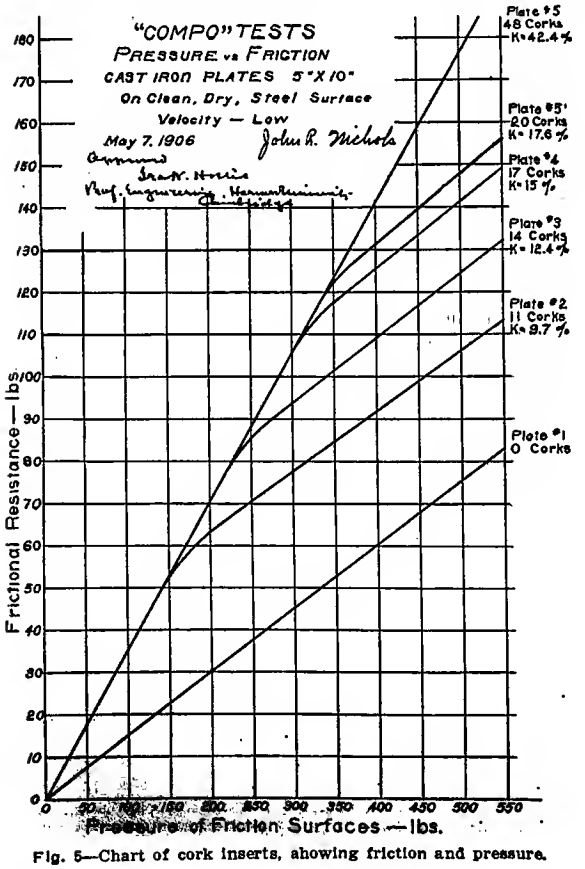

Fig. 5—Chart of cork inserts, showing friction and pressure.

get on to the surfaces, and in an automobile it is almost impossible to keep it off.

If, however, a clutch is designed for metal to metal contact, involving enormous pressures, it will not be very practical to insert cork as a final act of defense, because the conditions will not be the best for cork. Failures oftentimes result because the conditions that are necessary under certain circumstances are impressed into service under a change in the nature of the requirements. In the use of cork inserts there are two fundamental conditions to be taken into account, *i.e.*,

(*a*) When the pressure is not so high as to cause the metal to contact. The time when cork is in contact with metal.

(*b*) When the pressure is so great as to compress the cork enough to indicate metal to metal contact.

If the pressure is applied directly, as in the case of the loaded flat plate bearing upon a "platen," for the purpose of ascertaining the coefficient of friction, the resistance will be equal to the load in pounds, multiplied by the coefficient of friction in any given case, but if the pressure is increased enough to compress the cork and enable the metals to contact and to press on each other, there will be an added resistance which may be determined as follows:

$$R = f W + N A (K - a),$$

where R = resistance to motion in pounds;
W = total load on plate in pounds;
f = coefficient of friction of the metals used;
A = total area of the plate in square inches;
K = area of the cork in per cent. of A;
N = a constant, depending upon the nature of the materials and the prevailing conditions;
a = another constant.

This formula, devised by Prof. John R. Nichols, was extended and applied by him in the manner as follows:

The first modification of the formula is indicated as follows:

$$r = fw + N (K - a).$$

where r = the frictional resistance in pounds per square inch;
w = the pressure in pounds per square inch.

In a purely engineering sense, the formula is claimed to be accurate to a satisfactory degree, even above the critical point. The critical point, according to the authority stated, will occur as follows:

For cast iron:

When $W = 0.7\ A\ (K - 5.6)$
$w = 0.7\ (K - 5.6)$

For bronze:

When $W = 0.66\ A\ (K - 5.4)$
$w = 0.66\ (K - 5.4)$

According to the complex formulæ, the values of R and r may be found as follows:

For cast iron:

$$R = 0.16\ W + 0.118\ A\ (K - 5.6)$$
$$r = 0.16\ w + 0.118\ (K - 5.6)$$

For bronze:

$$R = 0.14\ W + 0.126\ A\ (K - 5.4)$$
$$r = 0.14\ w + 0.126\ (K - 5.4)$$

In all of the above cases the cork inserts are, of course, used in the cast iron, and in the bronze discs. The cork must be especially prepared to correspond with the quality known on the market as "Compo," as natural cork does not perform in quite the same way. A compact summary of the formulæ, taking into account the effect of a range of values, is given by the same author, as follows:

For cast iron (cork) on cast iron:

When W is less than $0.7\ A\ (K - 5.6)$
$R = 0.33\ W$
When W is more than $0.7\ A\ (K - 5.6)$
$R = 0.16\ W + 0.118\ A\ (K - 5.6)$

For bronze (cork) on cast iron:

When W is less than $0.66\ A\ (K - 5.4)$

$$R = 0.33\ W$$

When W is more than $0.66\ A\ (K - 5.4)$

$$R = 0.14\ W = 0.126\ A\ (K - 5.4)$$

For cast iron (cork) on steel:

The formulæ will be modified as follows:

$$R = 0.15\ W = 0.124\ A\ (K - 4.5)$$

$$r = 0.15\ w + 0.124\ (K - 4.5)$$

The critical point occurs when $W = 0.62\ A\ (K - 4.5)$ or $w = 0.62\ (K - 4.5)$.

The summary involving a range of values may be taken as follows:

For cast iron (cork) on steel:

When W is less than $0.62\ A\ (K - 4.5)$

$$R = 0.35\ W$$

When W is more tban $0.62\ A\ (K - 4.5)$

$$R = 0.15\ W + 0.126\ A\ (K - 4.5)$$

The above work has the sanction of Prof. Ira N. Hollis, also of Harvard, under whose supervision the tests were conducted. The deductions are much more complete and reasonable than usually can be attached to tests of this sort. They apply in this case to a marked degree, because they were conducted with a view to the automobile, whereas the tests generally available are of a nature not taking the automobile into account, or of so abstract a nature as not to directly apply. Prof. Nichols compiled a table for use in spacing cork inserts with a view to fixing upon the percentage of the total surface that the cork inserts should occupy, on a basis of quick and accurate results. The table is given here without modification. As will be observed, the cork inserts are pressed into holes, or sockets.

While the opportunity affords, it may be well to mention the fact tbat a new class of clutch and brake facings is now in use, *i.e.*, facings of asbestos, interwoven in a wire mesh in such a way as to afford the higher resistance of asbestos and the mechanical strength of wire. In a general way, it is quite possible that the action of these facings will be found to be with a critical point. In other words, they will probably be found to act differently under great pressure than will be the case with comparatively little pressure. In a twelve-hour non-stop run of a Chalmers-Detroit "30," over mountain roads, made by the author September 27, 1908, an opportunity was afforded to try out this class of facings on brakes, and it seemed to the author as if the initial friction (per pound of effort) was more pronounced than the later effort.

The results, on the whole, were very satisfactory, and the brakes were just as effective at the end of 240 miles of the hardest kind of work as they were on the start. The ordinary fabric would have given out long before the end of the run, as the author found by an actual run with another car over the same course. The Nichols formula would probably apply to the use of the asbestos products as well as to the cork inserts. subject to a correction of the constants of the formula. In the case of the asbestos (wire mesh) products, the pressure can be applied to an extent such as will compact the fiber enough to engender more nearly the metal to metal conditions than can be possible with the fabrics in which there is no metal binder. It is true, of course, that the percentage of metal will be small, relative to the total surface, but it is true as well that the percentage of cork, if increased beyond certain points, does not evolve a corresponding increase in results. In other words, there is no occasion for having more than a certain percentage of the total surface covered by the cork inserts.

When it comes to leather, red fiber and such materials, there is no compounding of the effect on critical point nor a change in the coefficient of friction before the change in structure due to charring as a result of a greater temperature than the materials will withstand. Wood chars at about 550 degrees C., and bursts into flame at about 600 degrees C. Leather will show effect of heat considerably sooner, and the coefficient of friction will change as soon as the leather suffers any change in character. When leather is subjected to the combined action of pressure and heat it loses its oily condition and becomes "as hard as a board."

John R. Nichols

"COMPO" TESTS
D = DIAM. OF SOCKETS
S = SPACING
K = % OF CORK TO TOTAL AREA

In this "crusty" condition leather is no longer suitable for the purpose, because it will no longer act in the same way. The leather will not cling to the same extent, or anything like it, and as a consequence the spring strong enough to do the work with the leather in its most receptive state will be too weak when the leather becomes hard, unyielding and glossed over. Red fiber has the ability of wood (it is wood) as long as it lasts. It does not last long enough, as a rule, in work of an exacting character. Wood has long been used in its natural state for frictions in brakes and clutches, and it seems to be more durable than the fiber. In automobile work wood cannot well be applied, because of the spinning tendency, if the friction member is of any great weight, at a distance from the axis of rotation.

Coefficient of Friction in the Abstract.

It was said the tests given in connection with the cork inserts were at a low speed, such as that due to drawing a flat plate over a smooth surface at a low speed. This coefficient does not, of necessity, show what would follow were the friction members caused to rotate at a high speed. Indeed, there are clutches that will not engage at a high speed, and the motor has to be slowed down. In general, it is conceded that the laws of friction will be different as the materials and the state in which they reside are varied. We have to consider, then, the laws as follows: (*a*) the friction of solids; (*b*) if the solids are unlubricated; (*c*) rolling friction; (*d*) fluid friction; (*e*) intermediate conditions.

Rolling friction may be stated as the force required to slide one body over a relating body, between which bodies rollers or spheres are interposed, in some cases to reduce the friction of rolling and in other instances to the detriment of the process, if, in the latter case, the resistance is desired on a basis of the maximum.

In ball-bearing work, the absence of friction is the quantity desired, whereas in clutch work the friction is sought. In clutch work, oil interposes a slippery surface and the coefficient of friction of the oil is the result. Oil then is not as a roller.

Sand or other hard foreign substances might be regarded as having the properties of rollers. A bearing (ball) in thrust might be as a friction member if the thrust is high enough to pinch the balls into wedge-shaped grooves. The law of rolling friction was well set forth by Henry Hess in a paper before the Society of Automobile Engineers, at the summer meeting of 1907, in Buffalo. This question will be of no further profit here because clutches are not as yet built of ball bearings in thrust to such an extent as to engender enough friction to enable them to perform the clutching function.

Friction of Rest.—The force required to start a body sliding is called the friction of rest (Kent). This phenomenon requires a little elucidation in order that it will be the better understood. When a member is at rest, the oil is squeezed out (because of the time allowed) and solid friction is the result. The friction of rest, then, is substantially "solid friction," and instantly the body is caused to rotate oil is picked up and thrust into the space, with the result that the friction of the slippery surface is the phenomenon to be noted. In the one case the coefficient of friction is that of solids on solids, and in the other instance it is the coefficient of friction of the lubricant.

The Friction of Solids.—(*a*) If the solids are of a fibrous nature the friction will probably decrease as the pressure increases. The friction will also decrease with increasing speed. The cork insert illustrates this set of conditions adequately, in that increasing pressure results in a critical point if the pressure is increased enough to bring about metal to metal contact. The curve of friction is maintained (as the formulæ show) because, as the friction of the cork tends to diminish under pressure, the friction of the metal to metal makes up for the deficit.

(*b*) The friction of non-fibrous materials will be proportional to the pressure only (within the limits of abrasion). Here, again, is evidence of the fact that a soft, yielding mass is of considerable advantage, if the mass is backed up in such a way as to allow of solid friction at the higher pressures. The reason for this lies in the fact that the soft yielding mass will afford the maximum resistance at the lower pressures and specds, while the later metal to metal contact will introduce the increasing resistance with increasing pressures and speeds.

(*c*) Increasing hardness is attended with decreasing resistance. This is adequately illustrated in leather facings when they become charred and glossy. Hardened steel discs also act in the same way. The spring pressure in a clutch will have to be greater for hardened steel on steel than it will have to be for bronze on steel or bronze on cast iron.

(*d*) The limit of abrasion is the limit of ability in clutch work at any rate, and this limit will increase with the hardness and toughness of the materials in contact. Hardened steel on steel, then, possesses the virtue of a high limit of abrasion, and can well sustain high pressures.

(*e*) If the surfaces are lubricated, it is the friction of the lubricant that must be taken into account up to the time the pressure is high enough to expel the lubricant.

Unlubricated Solid Friction.—The behavior of unlubricated solids, caused to slide upon each other, is such as to render the mistakes of designers fully accounted for. They sometimes use the coefficient of friction, as determined at a low speed, assuming that it will represent the friction that will obtain at a high speed. On the contrary, the unlubricated friction will decrease with increasing speeds, at first rapidly, thereafter less rapidly, and ultimately follow no man's law; in practice, at any rate. To be safe is to allow for a fall in the coefficient of friction in clutch work wherein the lower friction is a detriment, since friction is what is wanted. It is a well understood fact that bearings, for illustrations, run easier at higher speeds than they do at low speeds. This is true if they are lubricated or if they are not, up to a certain point.

Fluid Friction.—This is a phenomenon that should receive some consideration in clutch work because of the drag of the clutch, due to the fluid friction, in the class of clutches of the disc type in which the discs are submerged in oil. Fluid friction has recognized characteristics, as follows:

(*a*) The friction is in direct proportion to the wetted surfaces, hence in direct proportion to number of discs in clutch.

(*b*) So long as the oil stays between the plates (discs) the fluid friction is independent of the pressure.

(*c*) The friction is proportional to the square of the relative velocities at the higher speeds. The drag of the clutch will then increase enormously with the speed of the motor.

(*d*) If the speed is low, the friction will be proportional to the velocity.

(*e*) The friction will not be influenced by the generic nature of the metals in contact. This is to say, as long as it is fluid friction it matters not of what metal the discs may be.

(*f*) The degree of smoothness will have some bearing, but clutch discs are never rough enough to have any influence on the friction of the fluid. Were they put in rough they would promptly wear smooth.

(*g*) The resistance (drag of the clutch) will be proportional to the density of the fluid (oil), and the viscosity of the fluid will also have a bearing on the performance.

(*h*) The unctuousness of the fluid will have bearing upon the performance of the clutch, as is adequately proven from the fact that light grades of cylinder oil will not act well until tbey are charged with their own weight, approximately, of kerosene. The unctuousness of kerosene is almost a minus quantity, while the light cylinder oil is of a high value.

(*i*) The mobility of the oil has a considerable bearing on the performance of the clutch from the point of view of drag. If the oil falls off in density as the temperature increases, it is a mobile product and not so desirable for a clutch, for the reason that the density of the oil will be very marked when the temperature is very low, as it would be in winter.

Some Coefficients of Friction.

Leather: (Gen. Morin).

(*a*) On clean, dry, smooth metal	0.56
(*b*) On wet metal	0.36
(*c*) On greasy metal	0.23
(*d*) On oily metal	0.15
*(*e*) Dry, compressed, charred leather; on greasy, polished metal	0.08

*The effect of compressing and of the dry polished surface is a condition peculiar to the automobile clutch.

As will be observed, leather furnishes all the conditions between the most satisfactory possible, when it is new and well applied, to the most abject failure, from the clutch point of view. No motorist of experience has escaped the two extremes.

The question of the applied pressure is one that probably belongs to lever systems, in so far as the several modes of application are concerned. In the main, however, it does not seem desirable to separate the subjects. The foot pressure should not be so little as to render it impossible to use the pedal as a foot rest. On the other hand, the pressure should not be so great as to make it tiresome to press the pedal and hold it down. Forty pounds should be about the right pressure, with the clutch open and the initial pressure should, and would, be less.

(To be continued)

THIS IS WONDERFUL, IF IT IS TRUE.

This description is from a Chicago daily paper. It is doubtful if even the maker of the car could recognize it: "The transmission is on the floating type rear axle, and a drop frame is used, with herringbone gears for quietness. There is an 18-inch steering wheel, the ball-bearing knuckle making it exceedingly easy to steer. There is a fan on the flywheel and four brakes. We use the three-point motor suspension, aluminum boods and fenders and geared lubricator. The body is of hand-hammered aluminum and there is seating capacity for six people. Tbis gives a car without noise, jar or vibration and with speeds of from five to fifty miles on the high gear."

LETTERS INTERESTING AND INSTRUCTIVE

CESSIVE FUEL AND OIL CONSUMPTION.

THE AUTOMOBILE:

91.]—Your department of "Letters Interesting and Instruc- leads me to write the following: I have an eighteen-horse- runabout with rumble seat, equipped with a Schebler car- r and a ten-gallon gasoline tank. There is absolutely noth- rong with the running of the car, but the amount of lubri- oil and of gasoline used seems to me rather excessive. On aturday I made a demonstrating trial over a known course nty miles. At the end of the run I had used one quart and int of lubricating oil. Turning round, I made the run di- back to the starting place, a second twenty miles, and at the this I had again used a full quart and pint of oil. In noting moke from the exhaust at all times during the run, there wae ess of this oil being burned in the cylinders; the engine at e misfired, until at the end of about fifteen miles, when the plug of the right-hand cylinder was found to be badly . After changing the plug the balance of the run of twenty- iles was made with no trouble whatever.

ng the trip of forty miles six gallons of gasoline were con- and yet at no time was there a single misfire in the ex- or puffing in the carbureter, giving any indication of either h or too weak mixture. There ie one fact that seems hard lain, and that is that the oil thrown off by the flywheel itself through the hinges and openings of the hood and along enings between the hood and the frame.

you give me any information that will prove of value in a ke this? W. L. H.

ville Center, L. I.

sooted spark plug indicates a slight excess of oil fed to linders, but the principal loss is evidently by leakage, as by the oil forcing itself through the joints in the hood. ace for oil is inside the engine, not outside, and when it to appear on the hood or to drip from underneath when is standing still, it is a safe indication that there is some- wrong. The principal source of loss will probably be to be around the bearings of the crankshaft and the gear- Some sort of oil-retaining device ought to be fitted on bearings, and these may require cleaning or fresh packing. car has been in use long, the bearings themselves may be nd require adjustment or even replacement. In case the have neglected to provide for any oil-retainer in the and it is found impossible to make the bearings tight oper adjustment, you may be able to fit some device your- serve the purpose.

gasoline consumption of a gallon for every 6 2-3 miles inly unreasonable for such a light car, and it seems im- that that amount could be passing through the cylinders giving some unpleasant indication of its presence. We uggest that you verify the measurements carefully, mak- that no gasoline is drawn from the tank for cleaning or rposes during the test, and that there are no leaks.

AUTOISTS LIKE TO BE COMFORTABLE?

THE AUTOMOBILE:

]—Can you give me information about the public or owners automobiles? Are they looking for more comfort as to et? Say, for instance, riding for a few hours or a whole nped up in the car you would like to rest your feet or change ition. From sitting to a lying-down position would greatly the monotony. Do you think a foot reet would be in de- at would not take any room from the car, only when in have an article that I want to bring before the public, want to patent, but am a little backward. Can you give encouragement? J. P. HOPPA.

ukee, Wis.

ave no doubt that the automobiling public in general gladly welcome any device which would increase their provided the price were no more than commensurate increased enjoyment. But there are already a number rests on the market which fold up when not in use, and rs next year will include them in their regular equip- The lying down device, however, hardly seems likely to the comfort of traveling over ordinary roads.

SOME QUERIES ABOUT THE TRANSMISSION.

Editor THE AUTOMOBILE:

[1,593.]—I would like to ask you several questions and would be much obliged to you for answering them:

1. How is the transmission employed on the Cameron car constructed, and how does it work?

2. Could you tell me what advances have been made toward eliminating the differential gear? What devices have proved successful?

3. Would you explain the construction and operation of a gas turbine? Are there any you may know of that could be seen in operation? A. M. W.

New York City.

1. The change-speed gear-set (popularly misnamed the "transmission," which properly includes the entire drive from the motor to the rear wheels) of the Cameron car consists of a single short shaft carrying three spur gears, to give the three forward speeds, and the large driving bevel. This large bevel meshes with the bevel pinion on the end of the propeller shaft, as is customary. The short shaft in question is placed transversely, or parallel to the rear axle, and is carried on a heavy yoke that may be rocked up and down, a large spur gear being bolted to the case of the differential. The entire gear-set, bevel drive and differential, are contained in one small housing at the rear axle. In order to obtain any one of the forward speeds, the pinions in question are shifted along the short shaft mentioned, until the one representing the speed desired is exactly opposite the large spur gear on the differential. The shaft is then rocked downward, engaging the two gears face to face, and is locked in place, the entire operation being accomplished by a simple movement of the side lever. To go from one speed to another the lever is manipulated in the same manner, the operation consisting of unlocking the speed then in, shifting the shaft forward out of engagement, sliding the new pinion into line and again locking the gears together—something that sounds complicated in a description, but is quite the reverse in practice. The great advantage of this gear-set is that the pinions are engaged face to face, making no side contact, as in the ordinary form of sliding gear. The reverse is obtained by an intermediate pinion that is only thrown into engagement for this purpose. In coasting with the gears in neutral, the rear axle turns entirely free, and if the clutch is out, the propeller shaft and all the gears are idle as well.

2. There have been a great many attempts to eliminate the differential, but so far as our knowledge goes, the only one that has actually survived and been applied to any extent, is known as the Hedgeland axle, which is an American invention and is made in this country. Its principle is that of permitting the outer wheel, which has the greater distance to cover in traversing a curve, to run free, or ahead of the inner wheel, which, for the time being, transmits all the power.

3. To our knowledge the only gas turbines in actual operation are in use in France. The principle consists of the utilization of the pressure generated by burning a mixture of gas and air in a retort, against the blades of the turbine rotor in much the same manner as steam is employed, the modifications necessary being those required to handle the gases at the extremely high temperatures involved. A detailed description of this turbine may be found in *Cassier's Magazine* for January, 1907.

POSSIBLE CAUSE OF CARBURETER POPPING.

Editor THE AUTOMOBILE:

[1,594.]—In regard to letter No. 1,578 in the issue of October 8, Mr. Hutchings may find that his trouble is due to scale of metallic hardness having been formed on the valve stems and their bearings. In starting the engine under this condition, the camshaft speed is so low that the full force of the valve springs cannot be used to seat the valves, thereby allowing them to stick by reason of the scale. At a higher speed, however, the cams get from under the valve stems quickly enough to allow the seating of the valves in spite of the scale. The popping in the carbureter

ould thus be due to leaky inlet valves. To remedy this, remove ne valves and scrape off the scale, both from the valve stems nd from their bushings. I think this will remedy the trouble.
Ithaca, N. Y. CHARLES E. YATES.

We do not quite follow your reasoning with respect to the ull force of the valve springs not being available to seat them. t is evident that the springs exert the same force irrespective f the speed of the camshaft. If the valve stems really were ticking, the missing or popping would be more likely to occur t high speeds than when running slowly, owing to the valve not aving sufficient time to return to its seat. In fact, we think hat if Mr. Hutchings has not already discovered the source of is trouble, he would do well to make sure that the inlet valve tems are not too loose, as leakage of air through the guides on he suction stroke would have the effect he described.

MORE ABOUT PERCENTAGE OF DIFFERENCE.

Editor THE AUTOMOBILE:

[I,595.]—I am sorry we still disagree, but since you say I have ide-stepped the question I will try to return to it. We began alking about the vibration of a single-cylinder motor of a given ower and comparing it with motors of like power and more ylinders. I explained that two cylinders would give impulses of alf the power and twice as often, so that the vibration effect would be but one-fourth that of the single cylinder. Likewise hat three cylinders gave impulses of one-third the power and hree times as often with one-ninth the vibratory effect, while our cylinders gave one-sixteenth the vibratory effect given by he single cylinder of the same power. So the fractions refer not o each other, but to that single-cylinder impulse with which ve started.

In the wooly West where I went to school, every fraction presupposed a unit. And that unit had one hundred per cent., nine ninths and sixteen sixteenths. It is preposterous to assume one of the three fractions used as the unit base of comparisons. But if his is to be done, why select the one-ninth? The one-fourth mentioned is larger and more important. Or why not the one-sixtesnth? The use of this as a unit or base for comparison would give a perentage difference of 78. But everybody knows that the multiplication of cylinders rapidly reduces the vibration, and it would be he height of absurdity to tell a user that there is 78 per cent. lifference between cars of two and four cylinders in the matter of vibration, for his own feelings tell him more reliably. Your answer to C. W. M. rightly indicates very little difference. My hanke to "Cincinnati." His brand of arithmetic is all right.

I pride myself that in my arithmetic, as in other matters, I ry to stick to the plainest English of which I am capable, and am disappointed that I did not make it clear that the public had been offered side-entrance surreys for years before the rearentrance French freak ever was seen. They were offered wood wheels before they bought wire ones. They were offered gasoline rigs that ran before they swallowed the dinky steam toys and sickened so badly on steam that the really fine steamers now on the market are regarded with suspicion. Magneto ignition was an accomplished fact in America ten years ago, but the public are really just beginning to find it out. And the list can be extended much farther.

The side door is an imported nuisance. It was designed to shut the high-born lady in from the vulgar crowd, and will always be used by those who think they must be exclusive, but watch the growth of the practical surrey without the doors. Of course the doors serve a useful purpose in that the tires and repairs so frequently piled in the rear can not fall out, but rigs are getting better every year, so this need is passing. The enclosed box stall is a good dust receptacle, and this alone is enough to condemn it. In properly designed rigs the rear seat can ride nearly as easily as the front and with no more need of doors to keep the riders from falling out. I again say that on subjects new to it the public opinion is usually wrong. Watch the light car with light motor displace the heavy one. CHAS. E. DURYEA.

Reading, Pa.

We are glad that you have again stated the subject of the discussion, as it had dropped completely out of sight. In comparing the vibration of a three and a four cylinder motor, if the vibration is assumed to be in the proportion of one-ninth to one-sixteenth, there is a difference of 43.78 per cent. between the two. We have already demonstrated the way in which this result is obtained, and if you have any doubts as to its correctness you had better consult some fourth or fifth year school arithmetic. But we do not admit the correctness of your method of stating the proportionate vibration. Assuming that it is correct for the cylinders alone, which is doubtful, you make no allowance at all for the flywheel. Of course it would be preposperous to say that there is 78 per cent. difference between the vibration of a two-cylinder and a four-cylinder motor, no matter what brand of arithmetic was used, because all such motors have a flywheel of suitable size. The vibration of a motor depends on many things besides the number of its cylinders.

As to the poor, much-abused public, it may have shown its wisdom in some of the very cases you mention, by buying cars in which the quality of the material and workmanship was not subordinated to a few talking points. And side doors will keep out a good many cold drafts this winter.

A PLEA FOR SIMPLIFYING AND STANDARDIZING.

Editor THE AUTOMOBILE:

[I,596.]—In all the hill-climbing contests which have come under my notice the engine ratings have been based on the piston displacement, and invariably the volume is expressed in cubic inches.

This is one of the mathematical absurdities that have descended through generations and have produced mental habits hard to break. Always we think of volumes as having rectangular boundary lines, and we must convert all forms, however regular and common they may be, to the cubic form before comparing them.

So also we think of surfaces and sections as squares, hence our units of area are always square, and we go on converting the value of circles and cylinders and spheres into terms of squares and cubes, for each equation, requiring the use of a long decimal multiplier or divider, wearing out gray matter, better devoted to more useful service.

When we get away from this worship of the rectangular god, we are free to set up a new and more convenient rule for comparing volumes and areas, viz.:

When volumes or areas of like form are to be compared with each other, the unit of measurement should be of the same form.

The electrical people have adopted the "circular mil" as the unit of sectional area for wire, etc., which is much more convenient than a square mil, for it requires only that the diameter in .001 inch be multiplied by itself to give the sectional area, and the diameter in .001 inch of a wire of any desired area expressed in circular mills is the square root of the area.

d^2 = area, is a much shorter equation than d^2, 7854 = area, or nR^2 = area, and for purposes of comparison a much better one.

Why should not the engine builders and users adopt the cylindrical inch as the unit of piston displacement and cylinder capacity. Then the equation for displacement would be d^2L = volume, the proportion would remain the same as if reduced to cubic inches.

Thus the displacement of a cylinder 4" diameter with 6" stroke = 96 cylindrical inches or 75.3984 cubic inches.

The displacement of a 6" cylinder with 4" stroke = 144 cylindrical inches or 113.0976 cubic inches.

96:144::75.3984:113.0976. You see, it is just the same, and if you took your choice without prejudice you would take the shorter one expressed in whole numbers.

It is as easy to convert the volume of irregular cavities such as the compression space into cylindrical units as cubic units, the ratio between them being of course 1 to .7854.

The sectional area and volume of intake and exhaust pipes, the area of any circular opening such as valve ports could bets be expressed in circular and cylindrical inches.

Simple and easy understood methods of comparing one engine with another would be a boon to the automobile user, who is not always an engineer; neither has he a slide rule with him all the time, but he could readily multiply the diameter by itself and that product by the length of stroke. The calculation usually involves whole numbers or simple fractions, and could be done mentally.

There should also be a standard of speed at which an engine is rated, or rather there should be two points at which a variable speed engine such as used in an automobile should be rated.

Various compressions and valve timing may give an engine a high power at high speeds at the sacrifice of power at low speed, and vice versa; so it is hardly fair to compare two engines of the same bore and stroke at only one speed. Hence a rating should be given at a point between 400 and 600 r.p.m. (the normal running speed) and between 1,200 and 1,600 r.p.m. (the point of greatest output).

The power curve in most engines rated at from 30 to 50 horsepower is a rising one up to from 1,200 to 1,600 r.p.m. At some point in this range, the inertia and other losses which are rapidly rising compensate any increased power due to speed, the curve flattens out and shortly begins to drop.

Why not establish these extreme points in some engineers' convention as a standard of speed for power rating, publish it widely, and thus "put a crimp" in the practice of trading in ambiguities and fairy tales. FREDERICK PURDY.

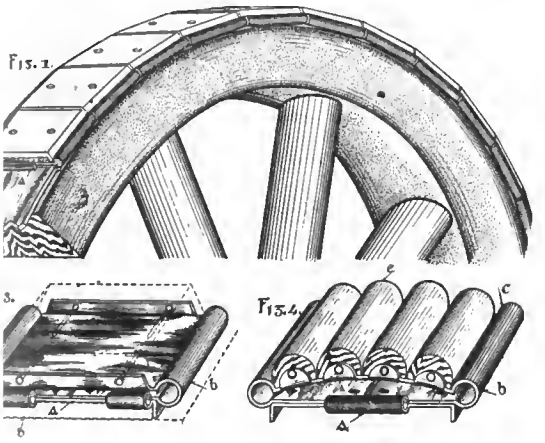
TION SPRING WHEEL FOR POWER VEHICLES.

ır THE AUTOMOBILE:

97.]—I have designed a new tire for heavy commercial ve-
, and I wish to submit it to your judgment for criticism. I
ully aware of the great virtues of the pneumatic tire, and am
oolishly attempting any improvement in that direction. The
matic tire cannot he even approached. It is peerless, and the
gold of the tire industry.

tire is especially intended to eupplant the solid tire of pure
ər. I think it will give just as good service, last much longer,



From the Patent Drawinge of Mr. O'Meara's New Tire.

ost less. The solid tire of pure ruhher gives fair service under
loads while it lasts, hut its life is indeed short under an unful load, whether it he a continuous or a sectional construc-

My aim is to design a mechanically constructed tire that afford some resiliency. Something that will hold fast to the hery of the wheel of a truck making 20 miles an hour.

ompanying my letter you will find a sketch of the tire in refe, also a photograph of a model. In the sketch ie shown a nuous chain of douhle flat metallio springs, shod with hlocks k, secured thereto with wire nails, and forming an annular of spring sections removahly secured to the felloe of an ory artillery wheel. These sections can he removed individually, nay be secured to all compression spoke wheels of ordinary ruction without alteration. It is a formidable spring, and properly designed and mounted cannot be disturhed. It is nely low, and hecause of ite form can he easily eecured to heel and becomes a part thereof. It is a truee in itself, of nse reeistance for its weight, and effectually unites even a ection of wood to the wheel. It is formed of sheet steel, and, without guides, pivots, sockets, etc., which cause friction rouble, it is noiseless.

s extremely hard to get anything in a sectional type of tire will stay fast on a power-driven wheel. Yet I believe that ng-looked-for mechanical tire will be sectional. Some who nad experience in spring wheels have finally come to the con- n that a plain block of wood is the only thing that can stay wheel. But a plate is necessary, and the epring shown on heel being, properly considered, a cushion plate, a section of mounted thereon, is evcn hetter eecured than when attached y to the rigid felloe of kindred material, because the spring stion, having a slight yield and a slight swaying lateral movill neutralize the most severe shocks, while the sections will n any weight that the wheel can.

design of spring shown in Fig. 4 is capahle of considerahle and it must be shod with two or more sections instead of one block. The circular sides will not shear. They will bear times the weight that the spring can at the center, and, not rigid, they will neither rock the spring nor collapse. These sections should be diagonal and rest diagonally on the wheel, llowing two or more sections to touch the road at once and as many independent yielding surfaces, hesides giving the hetter traction and ahility to shed dirt.

importance of euccessfully covering this type of tire ie than any other consideration. These springs must he tight. The model that I have made is covered with sheep- This model is intended for lighter vehicles than motor trucks. vering is a continuoue plain piece of leather drawn over the , which are too close to preeent any edges to he feared. ood portions are twin supplementary rims adjusted from side. I do not fully approve of all the details in the con- on of the very wheels shown, but my principal ohject is to prove the adaptability of this spring as the germ of a epring wheel when shod with a block of wood or more suitahle material. The cushion plate and the hlock of wood are both practical. I helieve it to he the only spring that can be poesihly considered for the purpose. These are my own reflections. Now, may I ask what are yours?

DENIS H. O'MEARA.

Hamilton, O.

PISTONS, MAGNETOS AND STORAGE BATTERIES.

Editor THE AUTOMOBILE:

[1,598.]—What is the procese for figuring the diameter of piston rings for any size pistons? What is the composition of the cemsnt used for celluloid storage hattery cases? How may the armature of a magneto he tested for a ruptured wire? What is the prohable trouhle with a high-tension magneto when it delivers a feeble spark direct, and the magnets seem very strong—magneto perfectly clean? How many thousandths of an inch smaller ehould the piston he than the cylinder?

L. T. S.

It is impossible to give any formula offhand for the diameters of pistons or piston rings, and even if it were, such formulæ would be of very little practical use. The smallness of the quantities involved makes accurate figuring useless, as it soon exceeds the limit of accuracy of the tools. Most engineers go entirely by "rule of thumb." A good cement for celluloid is composed as follows: 25 parts shellac, 25 parts spirits of camphor, 100 parts 90 per cent. alcohol; apply warm. Another consists of fine celluloid shavings dissolved in 90 per cent. alcohol. The best way to test your magneto armature for a ruptured wire would be to substitute a new armature known to be in good condition, and observe the results. A magneto is a very delicate thing to experiment with, and when any trouble arises that cannot be cured by cleaning and adjusting the contacts, the best course is to ship it back to the factory immediately.

REFINISHING THE STEERING COLUMN.

Editor THE AUTOMOBILE:

[1,599.]—The steering column of my automobile is of steel tuhing and is hraes plated. The plating has worn off eo much that the post rusts, and this is difficult to remove. Does "The Automobile" know of any paint I could use to cover the column, and must this he specially applied? Or would an enamel he of eervice?

Milwaukee, Wis. A. S. H.

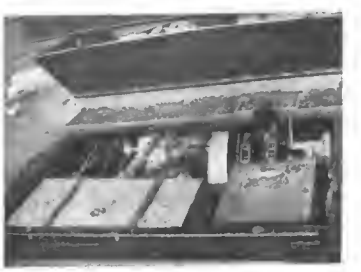
Many cars now have the steering column, as well as the levers and the radiator, painted to match the body work of the car, and this practice seems an improvement from every standpoint. No special paint is necessary. Enamel might serve the purpose.

INSTALLING 10-H. P. MOTOR IN AN OLD MODEL.

Editor THE AUTOMOBILE:

[1,600.]—Some time ago I promised to let you know the result of an attempt to install a two-cylinder 10-horsepower motor in a curved-dash Olds runabout 1903 model. It certainly was a decided success, and A. H. Phelps, a mechanical engineer, who owns the car, now has a fine working little runabout. Though this is a very mountainous country, the car takes some very stiff grades on high with perfect ease, and can make about 30 miles an hour on the level. Mr. Phelps did the job of making the change himeelf.

Mr. Phelps in His Reconstructed Olde.



Showing How the New Power Plant Wae Neatly Installed.

By having a transmission shaft made to bolt to the flywheel, he used the old transmission, and by making some slight changes he also used the old levers and connections. The two photographs which I send for illustrations show the complete car with Mr. Phelps at the lever, and the other shows where the engine is located in the chassis.

E. R. WELLS.

Keene Valley, N. Y.

CONCERNING THE SILENT KNIGHT MOTOR

By THOS. J. FAY.

'HE invasion of Europe by Americans and American devices is nothing new. The Silent Knight motor takes rank ong the invaders, although it cannot be said the same motor much of a swath in America during the time of its trial e. The reasons why this motor failed to win a place for itself ing the time of its sojourn in America, beginning some six rs ago, could be traced to environment more than to the ure on the part of the motor to perform.

Iad the motor been well constructed and properly applied, it bably would have failed to make its mark at that time, because period was one devoted for the most part to the types of tors as they then emanated from the factories of France and many. At that time cars were strictly luxuries and the fad s for a foreign "Red Devil."

'hat the Silent Knight motor failed to impress the designers America (not to mention users of cars), is an assured fact, l it is now that we learn of the taking up of this motor by the imler company and by the Minerva people also.

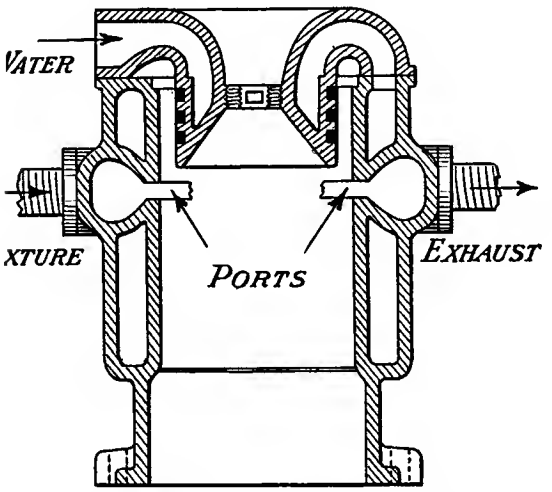


Fig. 1.—Cross-section of a Silsnt Knight Cylinder.

At all events, the motor in question is now being exploited by Daimler company, and it is reported generally that they have ndoned the conventional four-cylinder motor—on which they ays placed such great reliance—and more completely offer the antages of the new motor in their future cars.

'his motor as they are now turning it out, according to the st devices, differs only in minor particulars from the same tor, as we (in America) were accustomed to know it first ne six years ago. Presumably, the new product will reflect advances in modes of construction and in the quality of terials entering into the respective parts.

t would be untimely to say much by way of bragging about Silent Knight as an American product by an American, now t it has to be transplanted to make it grow. While we were sing the rainbow, by way of foreign designs, to the utter glect of "nuggets" lying under our feet, we were paving the y to our more or less future undoing, if **what** the Daimler npany says is true.

f the "beggar" proves to be rich, it will cause us a pang or o, and, having thus ruthlessly driven him away from our or, we will have small claim to the future glory that naturally ivitates towards merit. If, on the other hand, the Silent light motor fails to keep step with the claims now being de for it, we may pat ourselves on the back and flatter ourves that we know a ripe watermelon when we see it.

This motor in relation to which our English cousins are now making such a stir about will be remembered as one of the class formerly said to be valveless. The appellation "valveless" was a misnomer, on the ground that the motor has more valves about it than any other type of motor yet offered to the patient public, but the valves are not of the "poppet" genera.

Appellation "Valveless" Is a Misnomer.

The valves in the motor in question are of the well-known piston type, as they have long been known in steam engineering. True, the valves in this motor are not located in a valve-chamber, as they are in steam engines, but instead the valves are by way of concentric sleeves, concentric with the piston proper. There are two of these valve sleeves, one of which is next to the piston of the motor, and the other of which is next the cylinder wall. The valve so constituted is actuated by means of a linkage to an eccentric (one for each cylinder), just as in steam engines. The admission and exhaust ports are properly located in the respective sleeves and in the cylinder wall, in such a way as to afford the functions requisite to a four-cycle motor.

The whole arrangement is such as to afford timing of the openings as follows:

1. The inlet port opens before the exhaust port closes.
2. The exhaust port is covered by ths outer slesve.
3. On the inlst side the port is at full open, sincs ths slot in ths inner and the outer slesves ars in juxtapoeition.
4. Ths inlet port is still open at the beginning of the compression stroks.
5. The inlet closes before the compression exceeds the inertia component of the incoming mixture.
6. All ports remain clossd during the compistion of the compression stroke.
7. Ignition is with all ports closed.
8. Expansion of ths chargs with all parts closed.
9. Exhaust ports begin opening just before the snd of ths expansion stroke.
10. Exhauet ports wids open when ths pistons reach lower dead center.
11. Exhaust port remains open until beginning of suction stroke and until the inlet port opsns. (See Fig. 1.)

With valve timing such as would satisfy the conditions of operation of a conventional (poppet valve) motor. The time of escape of the exhaust is quite as long as would be the case with the conventional motor, and the incoming mixture is afforded the same time as in the conventional motor.

In these relations, then, the Knight motor would be quite up to the usual expectations, were a conventional motor in the mind's eye. On the other hand, the conditions would be no better.

Actual Gas Velocity May Be More.

There is a chance that the actual gas velocity will be more in the Knight motor for a given flow of gas on cubic inches, since the piston valves have to slide to a full opening; whereas, the poppet valves raise to full opening on all edges at the same instant and quickly, due to the shape and angular velocity of the cams placed to actuate the valve tappets.

As regards leakage, there is this to say. The poppet valves are usually tight and more to the point; any novice can render them tight if they become leaky. The Knight concentric sleeves are within the cylinders (out of sight), subjected to the temperatures prevailing and stressed by pressure of the piston in each cylinder.

Cylinders go out of round as a consequence of variations in pressure and of temperature, even if they are symmetrical in shape and of even texture. If they are symmetrical in shape it cannot be said of them that they are of even texture, and at best there will be three remaining conditions tending to make them go out of round.

If the cylinders do deform (and they do), the sleeves within the cylinders must deform also, or, what is worse, stick. If the sleeves resist deformation, they will cause oiling troubles, and

noise will be one of the products. The facilities for oiling are by the splash system, and it is not quite apparent as to how the oil will provide a slippery coat over all surfaces on both sides of the two sleeves and on the rubbing surface of the pistons as well.

Some of the surfaces are quite well concealed, and oil will be resisted in its search for a dry surface to cling to, especially

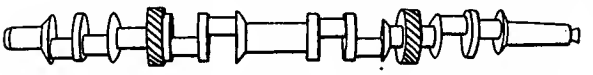

Fig. 2.—Complicated Shaft Required to Operate the Sleeves.

since the conditions are such that the oil must reach its place of lodgment in short time, or be sucked out again, ere it has a chance to reach its goal. Oiling troubles then would be more prone to attach to this type of motor.

Referring to Fig. 1, it is to note that the cylinder head is separable and that it protrudes down into the cylinder for some distance. It is water-jacketed, to be sure, but, as far back as twelve years ago, it was found (when this scheme was tried) that the water ports served as lodgments for foreign substance from the water and that it was best to eliminate the separable water jacketed head on that acount.

Claims Advantage for Separable Head.

The Daimler company claims there is an advantage in having a separable head, although they fail to call attention to the fact that the construction compels them to have it. Be this as it may, the separable water-jacketed head will be cooled by the water, if the same is not shunted away from the head by lodgments of foreign substances.

It has been found that holding bolts for separable heads are wont to stretch for two reasons; i.e., (*a*) because of the tension, and (*b*) because of the heat changes. These disadvantages are more than a theory without a practice to support it, and it was largely on this account that automobile builders expended thousands of dollars in devising and building special boring machines to finish cylinders with a blind end.

As will be observed, by again referring to Fig. 1, the head is provided with packing rings, in order to pack against the inner shell of the valve system. These rings are made in the same way as piston (bull) rings, and should work just as well, barring one circumstance. If piston rings stick in the slots provided to nest them, they fail to serve their purpose, and they will stick if they are not lubricated, or if they soot up. They are kept from sooting up by the movement of the piston, but, in the case of the rings for the head, they do not move, and they will soot up, and, as a consequence, they will not remain tight. If they do not, it seems a waste of space to say what will happen. If we take into account the ill effect of so small a leak in a cylinder, such as follows if a spark plug is not snug, this small leak, in comparison with the leak around packing rings if they do not nest properly, is as a pea to a plum.

Knight Has a Pretentious Eccentric Shaft.

The Knight motor has a very pretentious eccentric shaft, as will be observed by inspecting Fig. 2; a shaft, in fact, that takes on the characteristics of a crankshaft, and there are none of us who feel called upon to hanker after a collection of crankshafts in any automobile we ourselves have to pay for, drive, or keep in good repair.

This is not to say that the Knight eccentric shaft will fail to work, but it is to say that there can be no valid claim of superiority over a conventional camshaft of fair design and construction. In a steam engine, every engineer knows that the eccentric is very prone to run hot. Why should the eccentric behave any better because its geographical position is somewhat altered?

The reports of the Knight motor include a statement that the compression can be increased on the ground of superior cooling and because the poppet valves are eliminated. It is said, nevertheless, that the Daimler company will stick to the conventional compression (about 80 pounds per square inch), but it will be well to give this matter a moment's thought, for fear the claim of advantage by way of increased compression may be with the idea of concealing the facts in the case. In the first place, the cylinder head is no better provided with a water-jacket than is the case with motors of the conventional sort; indeed, it is possible to see how the reverse might be true, as before intimated. In the second place, the piston is not water-jacketed, and it is the piston that does the mischief in all motors, because a zone on the piston head reaches the highest temperature in all cases. In the third place, the cylinder walls in the Knight motor are not nearly so well protected by water-jacketing as are the walls in motors of the conventional sort, because the concentric valve shells intervene.

It is a well-known fact that two parts of metal in contact with each other will not transmit heat nearly so well as a solid wall of the same combined thickness. It will not be necessary to dig up proof of this contention, because every schoolboy knows it. In this case the conditions are even worse, in that the concentric shells must reciprocate and must have a bearing fit inside of cylinders that expand from 15/100 to 30/1000 of an inch, so that there must be an actual clearance equal to from 15 to 30 thicknesses of the oil film to prevent sticking of the members due to expansion from heat changes.

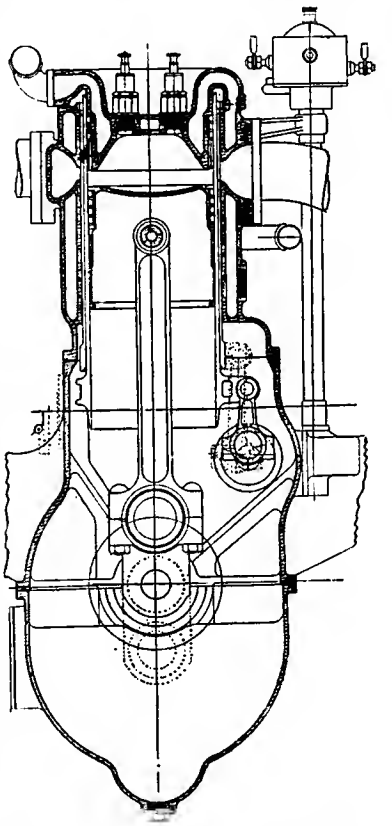

Fig. 3.—Cross-section Silent Knight Motor.

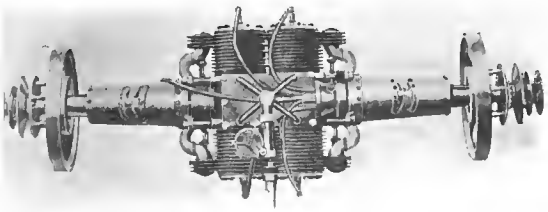
It has been pointed out that the valve system in the Knight motor, instead of the valveless product as originally claimed, is complex and extensive. From this point of view then, there is not a whit of simplicity. Take the question of packing rings. In a conventional motor the packing rings are limited to the pistons, while in the Knight motor there are two sets of these rings. The second set, as before stated, packs the separable head as it bears against the inner shell of the valve system. (See Fig. 3.) In this we see no migration towards the goal of simplicity, and in this we are dealing with packing rings, long regarded as fragile and prone to fail in service. Let us have another look at Fig. 2, and while thus devoting our time, remember that the double linkage required to actuate the two shells of the valve system is something to ponder over.

Dry batteries become inefficient in time, if they are near any source of heat. In such cases, to drill a hole in the sealing compound and spill some water in through the hole is a simple expedient. Seal up the hole, to prevent evaporation; give the cells a short interval of rest, and they will then be ready for service.

IRECT transmission of power from the motor shaft to the wheels without intermediate gears is accomplished the first time in the history of the automobile in- try." The foregoing statement precedes the announcement of Holsman Automobile Company, of Chicago, in placing upon market its new model, Holsman "Gentleman's Automobile." a pioneer in the construction of what is known as the auto- gy type, the Holsman Company is well qualified to speak, and special and distinctive feature that characterize the company's ducts, and which are set forth in a neatly printed and illus- ted booklet, make interesting reading for the thoughtful buyer. One of the most noticeable features of the new model is the tor, which is an air-cooled, four-cylinder, four-cycle type, ed at 26 horsepower. In the illustration below, the motor, nplete, with carbureter, twin mufflers, oiling device, ignition



Unit Power Plant and Drive of the 1909 Holsman.

paratus and transmission for both low and high gear is shown, ving an idea of the compactness of the power plant. In the spension of this unit power plant great care has been used at no vibration of the motor is communicated to the body of e vehicle, and is so attached that the whole machinery may be uickly removed from the frame for repairs or even for transfer another Holsman. Throughout the whole machine, either yatt flexible roller bearings or radial ball bearings are used, and the illustration at the bottom of the second column is shown ie rigid connection between two pistons with the roller bearings place, and two of the three 5-inch radial ball bearings used.

There are no gears in the motor, the inlet valves being auto- iatic and the exhaust valves are operated from the shaft without ny intermediate appliances, such as gears, push-rods, etc. The ubrication has been accomplished in a very novel way without ie use of an oil pump or similar attachment, by dissolving the equisite amount of oil in the gasoline, whence it is carried in ie form of a vapor directly to the parts where it is most needed. No oil adjustment is considered necessary, as the proper quantity f oil is always in proportion to the work required of the motor, or as the work increases the amount of the charge has a corre- ponding increase with its quota of oil.

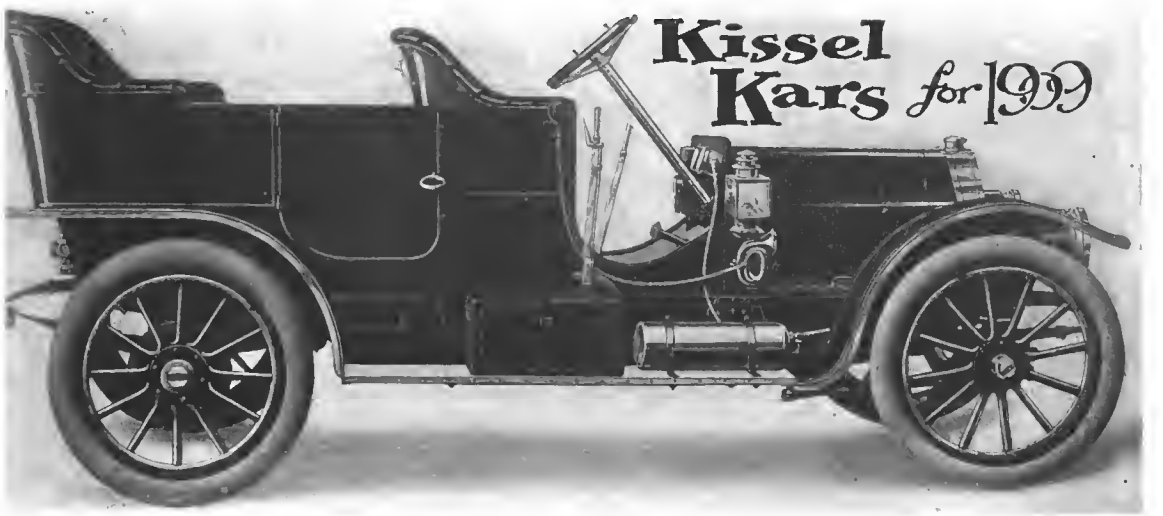
In the design of the transmission the Holsman Company has ollowed out its desire to make the whole machine as simple as possible, both the low and high speeds being direct from the motor shaft to the wheels, through the newly patented steel friction chain. One control lever of the rack and pinion type easily operates both forward speeds and reverse. There are no other change-gear parts or levers except the foot brake, and the vehicle starts and runs from zero to 25 or 30 miles an hour by friction of the steel chains operating on grooved sheaves on the ends of the motor shaft to the sheaves on both the rear wheels. In case of hills or mud, etc., sufficient to stall the motor on high speed, the low comes into action by engagement of sprockets on the motor shaft with the chain, and when the necessity for greater power has passed, the high gear automatically returns into operation by simply relieving the tension on the chains by the control lever. The reverse is accomplished by pushing the grooved pulleys on the ends of the shaft back into engagement with the channels or rims of the wheels, by the same control lever. The driving chains are wholly and automatically raised from engagement whenever the tension on them is relieved or the brake is set, or reverse is in action. Thus all operations of driving are accomplished with the power direct from the motor shaft to the wheels through the friction chain drive without the intervention

Crankshaft Blank and the Finished Piece.

of any countershaft or jackshaft, and the power is so sufficient that the company guarantees the motor to turn the wheels on any road surface whether the vehicle moves or not.

In the matter of conveniences, which go to make up a complete automobile, the manufacturers have provided some handy methods of operation. The motor shaft being across the car arrangement is made that the engine may be started from either side, and hand-in-hand with it goes the provision for steering from either seat, the steering lever being so designed that it can be turned either way, and operation is equally convenient from the right or left hand seat. The switch, ignition and carbureter adjustments are brought to the middle of the front seat so that the carbureter can be adjusted without stopping the vehicle. A weather-tight box is supplied in front and in the rear another compartment for carrying luggage, etc. Both the front fenders and the lamps turn with the wheels. In addition to this model there will be eight other Holsmans for the coming year.

A Pair of the Twin Pistons and the Shaft B



Forty Horsepower KisselKar Continued for 1909 in an Improved Form.

HREE chassis types of KisselKars are listed for 1909, one a carried-over type with improvements, the others new crea- . The carried-over style is a 36.1-horsepower, four-cylinder egularly rated at 40 horsepower. The new models are a 28.9- power, five-passenger car, also built in roadster and tour- t lines, and a six-cylinder 60-horsepower machine which, ac- ng to A.L.A.M., has a 54-horsepower rating. In all three the Kissel Motor Car Company, with its factory at Hart- Wis., follows the same design which can be summarized as cardinal constructions as cylinders in pairs with valves on eft side, cone clutch, selective gearset, shaftdrive, a general f Timken bearings, and double ignition.

e cars show many improvements over the constructions of resent year, many of which can be gleaned from the 36.1- power model, which is a continuation of this year's car. road wheels have been increased from 34 to 36 inches in ter; the wheelbase lengthened from 108 to 115; the I-beam lropped so that it affords a carriage 2 inches lower than this ; in the rear axle Timken roller bearings are used in front ear on the driving pinion; brakes have been increased from 14 inches in diameter with 3-inch width; the emergency is pulled instead of pushed in applying the brakes; instead making the tonneau 6 inches longer, gives room for additional seats. To these changes could be added a list of minor ones, all of which show the care with which the next year models have been worked out during the past year.

Of the two new models, the 28.9-horsepower one will doubtless be the popular branch of next year's output. It is made with a 4 1-4-inch square cylinder, conventionally designed with a two-part crankcase, three-bearing crankshaft, enclosed engine gears, and valves opened by direct lift from the camshaft, through lifter-rods with rollers on their lower ends; the crankshaft goes through the usual machining and grinding process and is carried on hand-scraped Babbitt bearings; the other motor parts, such as valves, camshaft, pistons and connecting rods are carefully manufactured. Lubrication is by mechanical force feed oiler, carried on the right rear motor arm; the Stromberg carbureter is fitted, and ignition is of the jump-spark type. In the ignition outfit is used an Atwater-Kent combination with dry cells, and Remy magneto with single unit non-vibrating coil, each operating with an independent set of spark plugs.

In the 40-horsepower four-cylinder, and the 60-horsepower six-cylinder, use is made of a 4 3-4-inch square cylinder, made in twin castings along the design identical with that of the little motor. In these the ignition is similar, except that in the six, when built for seven-passenger use, a Bosch high-tension magneto is fitted.

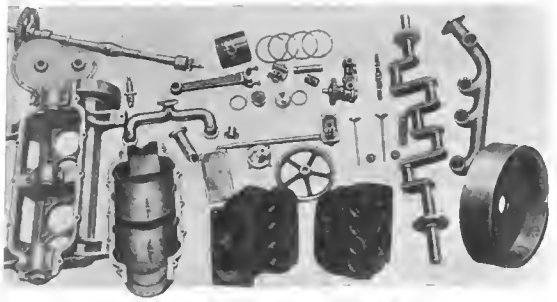
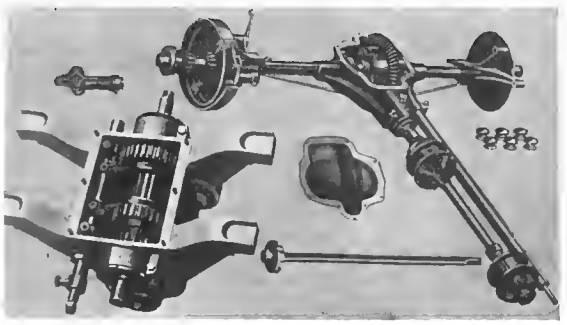
Motor of the KisselKar as Seen from Intake Side.

Conspicuous in the KisselKar transmission is the use of an inside change speed lever, which operates through a slot in the floor of the footboard, which location has been used to obviate the boring of the side member of the frame to accommodate the shifter sleeve attached to the bottom of the change speed lever. The transmission box finds support on the same



Chief Essentials of the KisselKar Motor.

bframe members which carry the motor, both of these import- it functionaries having a pair of integral side arms for support irposes. The Spicer universals, two of which are used in the opeller-shaft, are fitted with hardened and ground pins and ishings, and have metal covers for adjustment, giving proof gainst dust and the leakage of grease. The floating rear axle nstruction used in all models has the driveshafts supported on imken rollers, and the greatest improvement is the increased ze of the internal and external brakes. In connection with the loption of 3-4 elliptic springs in the rear, which is a change in irmony with several of the leading American makers this year, id which has been taken up by foreign makers during the last



Sliding Gearset and Rear Axle Driving Unit.

ouple of seasons, is the use of a conventional torsion bar be- veen the differential housing and the frame cross piece for osorbing the driving strain. Springs of this nature give a irticularly low body carriage at the rear, and afford good spring tion. The specifications of the different models are as follows:

-HORSEPOWER TYPE.

Motor, four cylinder, twin castings.
Bore, 4 3-4 inches.
Stroke, 4 3-4 inches.
A. L. A. M. horsepower rating, 36.1 horsepower.
Transmission, selective three speeds.
Rear axle, floating Timken bearings.
Front axle, dropped I-beam.

KisselKar Model LD 9, the New Car at $1,500.

Brakes, internal and external rear hubs 14 by 3-inch drums.
Wheelbase, 115 inches.
Wheels, 36 inches with Q. D. rim.
Rear springs, 3-4 elliptic.
Ignition, Atwater-Kent, or Remy magneto.

30-HORSEPOWER TYPE.

Motor, four cylinder, twin castings.
Bore 4 1-4 inches.
Stroke, 4 1-4 inches.
A. L. A. M. horsepower rating, 28.9 horsepower.
Transmission, selective three speeds.
Rear axle, floating, Timken bearings.
Front axle, dropped I-beam.
Brakes, internal and external rear hubs 14 by 3 inch drums.
Wheelbase, 107 inches.
Wheels, 32 inches with Q. D. rim.
Rear springs, 3-4 elliptic.
Ignition, Remy magneto with coil and dry cells.

60-HORSEPOWER TYPE.

Motor, four cylinder, twin castings.
Bore, 4 3-4 inches.
Stroke, 4 3-4 inches.
A. L. A. M. horsepower rating, 54.1 horsepower.
Transmission, selective.
Rear axle, floating, Timken bearings, re-enforced.
Front axle, dropped I-beam.
Brakes, internal and external rear hubs 14 by 3-inch drums.
Wheelbase, 130 inches.
Wheels, 36 inches.
Rear springs, 3-4 elliptic.
Ignition, Atwater-Kent system and Bosch magneto.

THE AUTOMOBILE CALENDAR

AMERICAN.

Shows and Meetings.

Dec. 31-Jan. 7..—New York City, Grand Central Palace, Ninth Annual Automobile Show, conducted by the American Motor Car Manufacturers' Association, with Exhibits by the Importers' Automobile Salon, Inc., Alfred Reevee, General Manager, 29 West 42d St.

Jan. 16-23.....—New York City, Madison Square Garden, Ninth Annual National Show of the Association of Licensed Automobile Manufacturers. M. L. Downs, Secretary, 7 West 42d St., New York City.

Jan.....—Fourth Annual Meeting, Society of Automobile Engineers. Dates to be announced definitely later. Charles B. Hayward, Secretary, 231 West 39th St., New York.

Feb. 6-13.....—Chicago Colleeum and First Regiment Armory, Eighth Annual National Exhibition, National Association of Automobile Manufacturers. S. A. Miles, Manager, 7 East 42d St., New York.

Mar. 7-13.....—Buffalo, Second Annual Power Boat and Sportsman's Show, Convention Hall, Dal H. Lewis, manager, 760 Main Street, Buffalo, N. Y.

Races, Hill-Climbs, Etc.

Oct. 24.....—Vanderbilt Cup Race, Long Island Course, auspices of Vanderbilt Cup Commission.

Oct. 31.....—Philadelphia, Sixth Annual Run of Automobile Club of Philadelphia for the Brazier Cup.

Nov. 5-7.....—Detroit, Three-Day Endurance Run, Detroit Automobile Dealers' Association.

Nov. 26.....—Savannah, Ga., Grand Prize Race, Savannah Automobile Club.

FOREIGN.

Shows.

Nov. 13-21.....—London, Olympia, Seventh International Motor Exhibition.

Nov. 28-Dec. 13.—Paris, Eleventh Annual Salon de l'Automobile, Grand Palais, Automobile Club of France (Pleasure Vehicles, etc.)

Dec. 20-28.....—London, Stanley Show, Agricultural Hall.

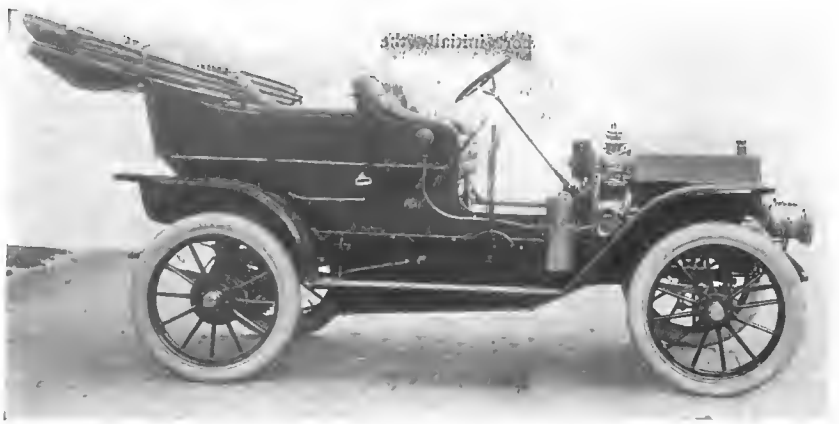
Dec. 22-29.....—Paris, Eleventh Annual Salon de l'Automobile. (Commercial Vehicles, etc.)

Jan. 16-25.....—Brussels, Show Organized by Belgian Chamber Syndicate, Palais du Cinquantenaire.

TWO NEW MODELS OF THE REO FOR 1909

MANY American automobile manufacturers have been striving for some time to produce a machine at a price which would be within the reach of the largest number, but were unable to do this for some years, largely because of the expense of production due to the newness of the industry. For 1909 the Reo Motor Car Company, of Lansing, Mich., is producing two new models similar to the 1908 design but at a lower cost, which it thinks will meet the requirements for this class of car.

Although the specifications for the 1909 models are the same as the 1908 cars with the exception that the wheelbase of the two-cylinder touring car and roadster is increased from 94 inches to 96 inches for the purpose of providing more leg room, some few changes have been made, all tending to add to the general improvement of the Reo product. The hood, which is similar to the 1908 type, has been reinforced at the corners with filler tubes extending through the top in place of the old style loose cover. The body is of aluminum coated metal with detachable rear seat. To insure proper lubrication grease cups are provided on all outside oil holes, spring shackles, steering spindles, and reach rods. The brake lever has been lengthened, giving a greater leverage and insuring better and easier control of the car. The front axle has been changed to the I-beam drop-forged type, with ball-bearing front spindles and 5/8-inch balls. The steering post has been given more rake to facilitate handling the car, and the steering gear has also been materially strengthened. The transmission brake drum is of a new design, in order that improvements tending to make the chain noiseless could be incorporated in the new models.



Five-passenger, 20-Horsepower Reo Touring Car for the Coming Season.

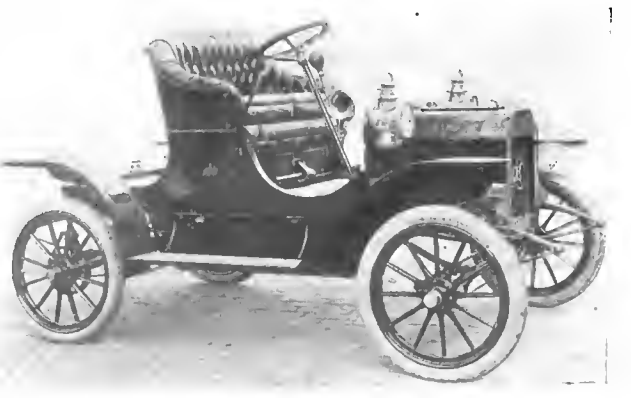
Model H 20 horsepower roadster, listing at $1,000, is built on the same chassis as the touring model except that in place of the tonneau a trunk box is fitted to the back and an extra seat, with a rail around the floor boards; in addition this model is furnished with a top as the regular equipment. Should the owner ever desire to convert this model into a touring car he can readily do so as the design is so arranged as to provide for this.

In the two passenger 10-horsepower runabout the Reo people are furnishing the same car for 1909 as the 1908 model for $500, with some changes for the better. The chassis is the same except that now they have made use of similar cam-shaft bearings and valve mechanism as is employed in the two cylinder machines. The front axles are also of the same type as the larger car, being I-beam sections from drop forgings; 5/8 inch ball bearings are provided on the front spindles the same as for the larger model and grease cups on all outside bearings. In general design the body has not been changed although the seat is similar to the one on the two-cylinder car, undivided, straight back, of aluminum metal material. The fenders on this model are all skirted the same as on the higher priced machine, which protects the body and lessens vibration.

In the matter of finish and general workmanship the Reo Motor Car Company has seen to it that when these new models are sent out from the factory they will make a showing both in appearance and performance on the road that will be in itself a tribute to the moderate and low-priced cars. The power plants of the Reo cars are so well known that comment seems rather unnecessary here; the same two and single cylinder engines with 4 3-4 inches bore and 6 inches stroke being used for 1909. The spring equipment—another vital part of a machine—has also proven itself efficient for the service required and no change has been deemed advisable.

The manufacturing of these two models realizes an old ambition of R. E. Olds and R. M. Owen, that is, to put on the market a touring car and a runabout at a popular price and of material which they felt would bring credit to the makers.

20-Horsepower Reo Roadster with Extra Seat.



Reo 10-Horsepower Runabout Listing at $500.

WILBUR WRIGHT TAKES PASSENGERS ALOFT

By W. F. BRADLEY.

LE MANS, Oct. 10.—Any man, even in France, who would maintain that Wilbur Wright is not at the head of all aeronautical experts would now be looked upon as a fool. Even the weak criticisms against the starting rail and the home-made motor are becoming less and less, experts and the public recognizing that if the workmanship is rough the machine is none the less the only one that can fly whenever its owner wishes to go aloft.

After showing that he could make time and distance records in order, Wilbur Wright began a series of demonstrations with two persons on board. First place was offered to a couple of journalists, the one American the other French. The representative of the New York *Herald* preferred the short initial flight to the second record-breaking soar.

"Sit well back in your seat, push that lever down when I nudge you elbow, then look pleasant; that is all you've got to do." Such were the brief instructions that Wilbur Wright gave to his passenger as he mounted into the roughly made seat stuffed with straw and covered with sacking. A minute later the two mechanics had started the engine by swinging round the propellers, Wright had buttoned his coat, pulled down his cap, then released the pin and shot off into the air.

Wilbur Wright Regulating Aeroplane; Henry Farman Thinking Hard.

Immediately it was evident that with two persons the aeroplane acted better than with only one. During the morning, when flying alone, the aeroplane had advanced with a gentle wave-like motion. With a passenger on board the line of march was so straight, the machine remained so accurately at the same elevation that it appeared to be guided through the atmosphere by invisible cords. As it neared the end of the field it descended a little, for all curves are taken with a considerable inclination, much in the same way as a cyclist would take a banked curve, but immediately after the original height was again attained and maintained. The curves are necessarily sharp, for the field, though about three miles in length, is not more than 400 yards in width, and Wright never uses more than 300 yards. Two complete rounds were made, lasting a fraction over three minutes.

Frantz Reichel, a Parisian journalist, was next invited to get into the machine, and another start was made with just the same ease as before. Instead of a couple of rounds of the field, however, the artificial bird soared around and around for almost one hour, the time, according to the official figures, being 55 minutes 23 4-5 seconds. As it was 5.20 P. M. when the flight was commenced, daylight had given way to dusk before the white flyer settled down again with its calm, collected Yankee pilot and its excited, vivacious French passenger.

Not a word had been spoken up aloft, for the simple reason that Wright ignores French and Reichel's English vocabulary is limited to "all right." But he made up for it on reaching ground, and the story of the tremendous rush at the starting line, the calm, majestic flight, broken only by the monotonous rattle of the open exhaust, the approaching darkness, the wonderful control, and finally the apparently tremendous rush toward earth, followed by a stoppage so gentle that not a tremor was felt—all this was told a score of times in that picturesque manner that only French can command, repeated to all on the journey to Paris and again related on the following day.

After a Sunday spent behind closed doors, the aeroplane was brought out early on Monday morning and an invitation sent to Léon Bollée to come for a flight. Though he needed no pressing, the pioneer automobile constructor was certainly surprised, for he scales 238 pounds, and such weights have not generally been associated with aeroplanes. But the "cent kilos" of the motor manufacturer were taken aloft as easily as the feather-weight journalists, and when Léon Bollée came to earth after 4 minutes 9 seconds in the air he was so delighted with the simplicity of operation that he wanted to make a flight alone. After the president of the Sarthe Aero Club, the vice-president, René Pellier, was also invited to take a ride. Again it was a heavy weight, for though M. Pellier has not the same corpulence as Léon Bollée, he can lay claim to close on 200 pounds weight.

The second flight lasted 3 minutes 54 seconds, but was immediately followed by two others, still with the same passenger, one being for 7 minutes 30 seconds and the other of 30 seconds only. A slight incident marked the last flight which, though not of great importance in itself, was sufficient to show the wonderful control that Wright has over his apparatus. His cloth cap being in danger of being carried away by the wind, Wilbur Wright put up his hand to save it, at the same time releasing his hold of the elevation rudder. The action caused him to touch the string by which the ignition cut-out is operated, and immediately the motor stopped. Seizing the lever again, Wright brought his machine back to earth a little more brusquely than usual, but without any serious shock.

Long and careful preparations were made before any of the two-men flights were attempted. The engine was dismounted, carried to the Léon Bollée factory at Le Mans, and thoroughly overhauled, the lubrication especially needing attention. While it was under repair the two propellers were changed for a pair of larger diameter and much broader face, the pinions also being changed to give a slightly higher speed, the ratio now being 33 to 10. The test on the block was not considered sufficient, however, and for one hour the motor was run in the open air while several thousand people stood round and fumed with impatience. Darkness came down while the motor was running, the crowds reluctantly melted away, and the aeroplane was wheeled back to its shed. Even next morning a flight with a passenger was not attempted immediately, but several rounds of the field made alone at a height of not more than one foot from the ground. It was doubtless done as a precaution after the accident in America, but was nevertheless one of the most remarkable demonstrations ever made, the areoplane just skimming over the ground, yet never striking any of the obstacles. Wright laughingly declared that he was practicing for an automatic shaving apparatus; he would attach the razor to the bottom of his machine and the customer would lie face upwards on the ground. It was only after five or six flights alone, each time at an increased height, that Wilbur Wright appeared to be satisfied and offered to take the first passenger with him.

One of the reasons for the special precautions is that the larger propellers come very close to the wire cables operating the rear propeller, and it was owing to this cable being struck by one of the propellers that Orville Wright's accident occurred. This, at any rate, is the explanation given by the brother in France, and in confirmation of the theory it was noticed that a special stay had been fitted to prevent any of the cables fouling the propeller, even, if for any reason or other, they were slackened off during a flight.

Wilbur Wright's method of control is simplicity itself. On the machine being placed on the starting rail and the 1,700-pound weights being drawn to the top of the pylone, the end of the rope is attached to the wooden carriage on which the aeroplane rests. This task is invariably attended to by Wright himself. Standing in front of bis machine, Wilbur Wright relieves the compression, orders his mechanics to give two or three turns of the propellers, injects a little gasoline through the two air inlets, then gives the order for a sharp pull on each of the propellers. Generally the motor goes off at the first pull, and immediately runs at its maximum, for there is neither spark lever nor throttle control, the pilot thus being under no necessity to occupy himself with the engine while in the air. If it is desired to stop, the pilot puts up his hand and strikes a piece of string attached to one of the wire stays. This short circuits the electric current, and, of course, causes an instant stoppage of the motor. The engine, which bas four separate water-cooled cylinders of 4 by 4 3-4 inches bore and stroke runs normally at 1,100 revolutions a minute. The gasoline supply is carried in a cylindrical tank suspended to the uprights, and sufficiently high to assure a flow by gravity. There is no carbureter, the engine being fed by direct injection, the pump being within the crankchamber and worked by worm gear off the camshaft. Inlet valves are automatic and exhaust valves mechanically operated, but sets in tbe cylinder head. Ignition is by Eisemann high-tension magneto, bolted to the engine base, and having separate coil immediately under the wooden frame on which the motor rests.

Wright and Zens Ready for Flight.

When flying, the pilot has to operate two levers only, the one in his left hand having a fore and aft movement only, and controlling the front elevation plains, and the one in his right hand having a combined fore and aft and left and right movement. If pushed to right or left, it operates the rear rudder in just the same way as the tiller of a boat, and gives a right or left turning movement to the aeroplane. If pushed forward at the same time, it elevates one wing tip and lowers the other; if pulled rearward, the wing tips are pulled in the opposite direction.

Léon Bollés, who during his flight closely watched the operations of Wright, declares that the apparatus is heeled over, by means of the curving of the wings immediatcly before the turn is taken and brought back to a horizontal position a few seconds before the turning movement is completed. As soon as thc aeroplane is brought back to a horizontal position, the wing, which was describing the shorter curve, regains its speed until it is traveling as fast as the other, and there is a very energetic leveling movement for a slight bending of the wings.

To tbe spectators, the turn takes place much earlier than is really the case. Wright first inclines his apparatus to a sufficient degree, and it is only when it is sufficiently inclined that he operatcs his rear vertical rudder and makes the actual turn. This phase of the operation of an aeroplane presents a very interesting study, and its scientific side has phases that never fail to interest.

Wright Captures Official Two-Passenger Record.

LE MANS, Oct. 12.—Still another record for Wilbur Wright. With Arnold Fordyce, a French journalist, on board, the white bird from Dayton has remained above the heather-covered military ground in the neighborhood of Le Mans for 1 hour 4 minutes 26 1-5 seconds, beating all two-man aeroplane records and fulfilling the conditions imposed by the Lazare Weiller committee.

It was not intended to make a flight on Tuesday, October 6, for the magneto had gone out of business and Wright had no desire to venture aloft until the motor was in perfect condition. Contrary to his usual custom, Wilbur Wright allowed an outsider to examine his carefully guarded machine, with the result that M. Girardot and Hart O. Berg's mechanic quickly diagnosed and remedied the defect of the magneto.

A little before six a start was made, the machine at once rising to a height of about 75 feet and remaining there despite the gusty weather for half an hour. At times a guest of wind would catch the aeroplane, causing it to make a dive that looked dangerous to the public. But Wilbur Wright was never caught napping. To each sudden change of the wind he replied by a manipulation of the rudder and a working of tbe wings that brought the artificial bird to an even keel and kept it on its right course to the finish. Later, in view of the approaching darkness, a descent was made to about 30 feet from the ground, and it was while at this height that the signal was given, by means of two white lights from the observation tower, tbat the previous record had been broken. When it was certain that he had been aloft more than an hour Wilbur Wright descended between the starting rail and the wooden shed which serves as home for himself and his artificial bird, when both machine and operator are at rest and hidden from the world at large.

Since making his record flight Wilbur Wright has been allowing aeronauts, journalists and othcrs to taste the joys of mechanical flight. Hart O. Berg, as a reward for his active organization of the Wright demonstrations in France, was given a sail in the air for 3 minutes 24 seconds. Mrs. Berg then took her husband's place, and for 2 minutes 3 seconds evolved over the heads of the spectators. Later in the day four other privileged individuals were takcn aloft with the American aeronaut for flights that lasted on an average 4 1-2 minutes.

The following day a group of Englishmen were initiated into the mysterics of aerial flight, Griffith Brewer, Hon. C. S. Rolls, Frank Butler, and Major Baden Powell being successively flown twice around the field. Madame Léon Bolée, following the example of her husband, asked for a ride and was rewarded by a flight of three minutes. Finally Commandant Bottiaux, chief of the Chalais army balloon station, was given a special demonstration, Wright starting low, then rising suddenly to a height of 80 feet, then again descending until he was so low that his skates almost touched the top of the heather, and his propellers disturbed the loose sand on the open spots.

FOUR-CYCLE FINALITY OF DESIGN.

It is with considerable reason that the present day our-cycle motor has been regarded as a close approach finality of design where its type is concerned, and that total departure rather than a modification of existing ethods has been looked forward to as the trend of the ature. In other words, the development of the two-cle motor to a point where it was considerably the su-erior of the present four-cycle type has been considered s the logical outcome of the persistent efforts of in-entors to improve the internal combustion motor. lence, the report that one of the foremost Continental otor builders has definitely decided to adopt a sliding alve type of four-cycle motor of American origin from ow on, comes as no little surprise.

The poppet valve has its drawbacks, but its advantages ver any other method of admitting and exhausting the harge hitherto developed have been so numerous and ractical that its abandonment has not been considered robable without a change of cycle. The handling f the fuel through ports of large area, opened and closed y the piston itself has always appealed to the designer f internal combustion motors as one of the chief prom-ses of the two-cycle type, in that it makes for a degree f simplicity to which the four-cycle motor, with its multiplicity of small parts, does not lend itself. But if this end can only be achieved by the employment of an equivalent amount of gearing to open and close the ports, wherein lies the advantage?

Simplicity, coupled with a high degree of efficiency, must ever be the chief aim of the inventor whose object is the advancement of the present day motor, and this is not to be attained by the abandonment of a form of mechanism that years of practice on a great number of motors has shown to be practical, in favor of a device, the chief merit of which is that it accomplishes the object in a different manner, but with no reduction in complication, relatively speaking. The mere fact that the result in view may be brought about by the new method is not sufficient to recommend it as being superior to the device it is intended to supplant, which appears to have been the basis upon which many so-called improvements in automobile construction that have since been relegated to the limbo of oblivion, were accepted. But in the present instance the reputation for conservative and consistent adherence to sound and well-tried principles of design on the part of the European house lends added weight to the report of the adoption of this new type, though further developments in this direction will be looked forward to with a great deal of interest.

* * *

A DEPARTURE IN BRAKE PRACTICE.

One of the last things that the average driver is anxious to have come in contact with the brakes of his car is oil, so that at first sight the proposal to employ brakes running in oil appears somewhat far-fetched, in view of the fact that even a small amount of lubricant is destructive of the frictional properties of two rubbing surfaces. This is true of metal, wood, or fiber surfaces, regardless of their character, but it is one of the peculiar properties of cork that its coefficient of friction with a metal surface is but very slightly influenced by the presence of oil in any quantity, and it is this that has made possible what may best be termed an oil-cooled brake.

The metals employed are bronze against steel, the former constituting the shoe or moving member, being shod with corks embedded in its face. This member is immersed in a bath of lubricating oil and is constricted against a steel drum, or expanded to contact with it, according to the requirements of the design. In one instance, a brake of this type has been employed on a car that saw 12,000 miles continued service of the most strenuous kind, but an examination revealed no perceptible wear in the braking surfaces.

This was naturally to be anticipated in view of the protecting influence of the oil, and the possibilities that it throws open in the way of improved brake service, as compared with the present day practice of employing frictional materials that must, of necessity, be renewed periodically, are limitless. It would be futile to attempt to pit either the water or the air-cooled brake against one constantly immersed in oil, as in view of the peculiar property of cork in not losing its frictional properties under the influence of a lubricant, the advantages of a generous supply of oil for cooling are obtained, without the attendant disadvantages of lubrication, which are naturally not to be desired where the object in view is the maximum friction.

FROM BOSTON TO NEW YORK BY MOTOR AIR LINE

BOSTON, Oct. 20.—When the Glidden tour paused in Boston, last July, Charles J. Glidden, the donor of the trophy, caused a brief commotion by letting out the fact that he was organizing a company with the object of establishing a passenger and freight service by balloons or other means of aerial transportation between this city and New York. The scheme was looked upon with considerable scepticism by the general public, but those whose memory carried them back a few years to Mr. Glidden's prophesies of the development of the motor vehicle, did not scoff. To-day it looks as if commercial aerial navigation may not be so very far distant.

Captain Thomas S. Baldwin, the aviator, who recently sold an air-ship to the United States government, was in this city yesterday and to-day and held a conference with Mr. Glidden concerning a contract for a dirigible balloon to be used by the Aerial Navigation Company in establishing the beginning of its New York service. The air-ship will be of large proportions, capable of carrying two passengers in addition to the operator, and it will cost about $25,000 to start the service. The money is available, so that there will be no bonds or stock to be floated as an additional burden on the air line. It is not proposed at once to undertake a direct New York service. In fact, the plans so far arranged are very conservative. They contemplate an air-ship service two or three times a week between a station to be established on the outskirts of this city and South Framingham, about twenty-five miles away.

The Boston station will be established at a point easily accessible for some of the lines of older transportation companies and the hydrogen gas for the air-ship will be manufactured at this station. Captain Baldwin has discovered a fabric for air-ship or balloon envelopes which he believes will help materially in solving the problem of preventing the waste of gas and he will use this material if he is given the contract for the balloon. If the Boston-South Framingham service develops as well as is expected other stations will be added and eventually there will be a through line to New York. The company has not yet progressed far enough to establish a freight and passenger tariff and is more interested in starting the line than in the profits.

AN INTERNATIONAL SPORTING TRUST?

The International Association of Recognized Automobile Clubs of the World has some grand plans in view for the future, and the story heard at Dieppe, to the effect that the scope of its operations would be extended to include motor boating and aeronautics, is now verified by an announcement from Secretary S. M. Butler, of the Automobile Club of America. This is to the effect that this club has been selected as "sole representative in America, which selection carries with it the sole governing authority in all international motor boat races or competitions held in the United States." The exact name of this new motor boating body is "The International Association of Yachting-Automobile." It is known that recently, under the direction of Dave Hennen Morris, the A. C. A. has been organizing a motor boat section, "and this division will be strictly a yachting adjunct to the club."

The principal objection of American automobile clubs against the present international organization is that it permits only one club to represent a country, and compels all other clubs to deal through the club possessing membership, even if that club is not selected by the entire association of clubs. A similar objection will undoubtedly be encountered in motor boating and also in aeronautics.

It is now generally known that an unusual combination of circumstances brought about the continuance of the A. C. A. as the international automobile voice from this country, and there are American clubs which are finding considerable fault with the arrangement consummated. What the future may develop seems to be a matter of varied opinion.

QUAYLE VICTOR IN SPEED TRAP FIGHT.

ALBANY, N Y. Oct. 20.—Oliver A. Quayle, a victim of the notorious Glens Falls speed trap, has won out in his stubborn legal fight to have his conviction set aside. Quite a howdydo followed Mr. Quayle's conviction, for the reason that he is president of the New York State Automobile Association, whose policy is to uphold the speed laws of the State. Mr. Quayle appealed his case, and the county judge of Warren County has just reversed the judgment of conviction.

This Glens Falls speed trap has been operated for the past two years and many a tourist has fallen into its clutches.

Mr. Quayle was arrested last June while touring with his wife. His contention was that the trap was improperly operated, to the end that injustice was done, not only in his case, but in that of many others. The result of his appeal confirmed his contention. It will probably encourage other automobilists to take appeals in cases of flagrant injustice and may possibly enlist the more active and general co-operation of local clubs in their efforts to have the evidences of speed law violations collected in a way that gives no opportunity for injustice.

A Y. M. C. A. SCHOOL FOR PHILADELPHIA.

PHILADELPHIA, Oct. 19.—Following the example of New York, Chicago, and other large cities, Philadelphia will have a Y. M. C. A. automobile school. On the 21st of this month the scheme will be inaugurated at the Kensington Y. M. C. A., at 1854 Frankford avenue, under the chief instructorship of William Vees, a well-known owner and operator of automobiles.

MASSACHUSETTS COURT RULES FOR LOCAL REGULATIONS

BOSTON, Oct. 20.—The full bench of the Massachusetts Supreme Court to-day handed down a decision in the case of the Commonwealth against Arthur Kingsbury, for which automobilists have been looking forward for several weeks, or since the case was heard at the Franklin county session. The court decides adversely upon Mr. Kingsbury's contention that the law permitting local boards of aldermen and selectmen to exclude automobiles from certain highways, is unconstitutional.

Mr. Kingsbury was arrested for driving his automobile on a highway in the town of Ashfield, from which the selectmen had voted to exclude motor vehicles and which was posted to that effect. He was convicted and upon appealing to the superior court lost his case in a jury trial. He then carried it up to the supreme court, which holds that statutory regulations of the speed of automobiles running on highways are reasonable and proper.

The court decides that the right of the Legislature, acting under the police power, to prescribe that automobiles shall not pass over certain streets or public ways in a city or town, seems to be well established upon principle and authority; and that the Legislature has the right to delegate police powers to aldermen of cities and selectmen of towns.

KNOX WINS FREE-FOR-ALL AT LENOX.

LENOX, MASS., Oct. 14.—Under the auspices of the Lenox Automobile Protective Association a hill climb was run here to-day. The course was up Church Hill and Aspinwall Park and finished at the Aspinwall Hotel.

A tangle has arisen over the sanction that has some elements of the humorous to it. It happens that a high priest of the metropolitan club with national aspirations is a patron of the hotel at the finish line and that mine host had much to do with the promotion of the meet. Little wonder was it that the landlord in question knew of no other organization that could possibly rule automobiledom than the club, over which once reigned his distinguished guest, and so wrote the manager of its touring bureau for information as regards a sanction. The touring official promptly replied that no sanction was needed, and mine host proceeded with his meet accordingly. M. L. Downs, of the A. L. A. M., a wise and prudent-going man, who went up to Lenox to officiate as judge, bethought himself before the climb had reached a conclusion to ask the promotor for his sanction and received the rather startling information herein above set forth.

The course was nine-tenths of a mile in length, with three sharp turns and grades varying from 9.15 to 12.5 per cent. There were a couple of accidents in the course of the contests. William Bourque, of Springfield, in a Knox collided with an iron post in Aspinwall and was thrown out. Floyd Knight, of Pittsfield, in seeking to avoid a collision with another machine, ran into a tree and put his car out of the climbing for the rest of the day. The Knox and William Bourque, however, were not injured enough to prevent their being gotten into shape for the subsequent climbs, or to prevent them winning the free-for-all and the event for cars from 24 to 40 horsepower as well. The summary follows:

FREE-FOR-ALL.

1.	Knox	38	William Bourque	1:19
2.	Stearns	30-60	William Swan	1:34
3.	Berkshire	30-35	S. H. Clapp	1:43 1-5

FOR CARS FORM 40 TO 60 HORSEPOWER.

1.	Stearns	30-60	William Swan	1:38 1-5
2.	Stilson	55	F. A. Knight	1:47 1-5

FOR CARS FORM 24 TO 40 HORSEPOWER.

1.	Knox	38	William Bourque	1:34
2.	Pope-Hartford	28	O. R. Hutchinson	1:47 1-2
3.	Pope-Hartford	30-35	Lester Phillips	1:57
4.	Buick	35-40	F. A. Knight	1:55 1-2
5.	Berkshire	30-35	J. E. Crabe	2:25 3-4

A HOTEL TRAIN TO SAVANNAH GRAND PRIZE.

That New Yorkers contemplating witnessing the Grand Prize race at Savannah may be assured of all the comforts of a well-appointed hotel and the finest cuisine, W. E. Conklyn, the general eastern passenger agent of the Seaboard Air Line, has arranged for a special train to leave New York at midnight on Monday, November 23. It will be made up of Pullman compartment sleepers, a dining car, and a buffet smoker. It will leave Savannah so as to reach New York at five o'clock in the afternoon on Friday. During the sojourn in Savannah the train will be side tracked and used practically as a hotel. A reasonable rate has been estahlished for the trip.

THESE MUNCIE HOOSIERS ARE HUSTLERS.

MUNCIE, IND., Oct. 19.—The Inter-State Automobile Company of Muncie, Ind., is setting a record pace in progress. It was only a couple of months ago that Thomas Hart, George Ball, William Ball, T. F. Rose, J. M. Waring and other Muncie capitalists formed the company and employed Claude Cox to design a car. On September 14 they got the deeds to some 40 acres of well-located land and by October 14 were putting under roof their first building, a fine structure of brick, steel and glass, 140x440 feet. They expect to begin turning out cars January 1, and have arranged for an output of 1,000 the first year. They will continue the erection of new buildings.

A NIGHT IN TRENTON WITH AUTO PATROL.

TRENTON, N. J., Oct. 12.—"Seems to me I've seen you before," remarked Captain Cleary, as he chewed his mustache reflectively and looked us over, when we arrived at Police Headquarters.

"Oh, yes; now I remember; violating Section 146 of the motor vehicle law, wasn't it?

"You don't care to stay this time, I suppose?" he smiled.

"Well, no; not exactly. You see, we came over to see the new White patrol and ambulance in its natural environment."

"Say, that car's all right. Haven't had time to make its acquaintance personally yet, but do you know, since we retired that old horse ambulance and the 'hurry up wagon,' your car has done the work of the two of them in one-third the time. The only trouble with it is that it's too popular. Guess we'll have to put a row of tacks in the seat. But there goes the bell."

It took us just four minutes to cover the mile and a quarter of busy street, dodging this way and that.

At a glance we realized what had happened. The horizontal ladder had given way at one end and the two painters at work upon it had fallen three stories to the sidewalk. One was unconscious, the other was suffering intensely from a compound fracture of the leg. The stretcher was produced from its compartment beneath the car, and in another minute we had our two patients on board and were off for St. Francis Hospital.

Trenton, N. J., Now Employs a White Steamer as a Patrol.

We were back at "Headquarters" in twenty minutes from the time we left, but were soon off again on another run. The car was wanted at the Court House to transfer a load of prisoners to the County Jail. This trip was a longer one, and by the time we got back there were two calls waiting. There was no time for dinner, for it was Saturday night and people were beginning to get drunk. The one at Box 23 was of the ordinary uninteresting variety; the other was a regular patron, and treated the occurrence with the indifference gained from many similar visits. Another call soon followed, and again we started. There had been a fight, it seemed, which fact we could well believe when we got there—either *that* or an earthquake—for there wasn't a whole window light left in the place. But the participants had fled, nobody knew where. We looked high and low, but evidently they had made good their escape. Returning to the "wagon" we noticed that the driver, who is never permitted to leave his seat, was missing. Fearing that he had met with foul play, we started round the building, prepared for the worst, when we came upon him. He was down on his knees, the tail lamp in one hand and his pliers in the other, pointing them down a cellar-way. At a glance we took in the whole situation. The driver had spotted one of the malefactors and, lacking a better persuasive, was brandishing the shiny tool in the face of the man in the hole, from which came in agonized tones the repeated assurance that he would give up.

"Well, I'll be hanged," said one of the officers, "if that kid driver ain't put it all over

WHAT IS DOING AMONG THE CLUBS

AGO CLUBS HAVE REAL AMATEUR CONTEST.

:AGO, Oct. 16.—Chicago's record for originality in the tion of motoring events was fully sustained yesterday the Chicago Athletic Association and the Chicago Auto- Club took part in the first amateur inter-club reliability match ever promoted, it is claimed. True, the present n is somewhat on this order, and while the clubs sup- y battle for the big trophy, yet in reality it is a struggle desmen. Not so was this affair of yesterday, for only ; drove, by which term is meant that no one at all affiliated he trade was permitted to drive. This brought about a ide contest which has done much to make motoring com- ns popular among the owners of Chicago.

inter-club team match stirred the town from the ground he leading dealers gladly turned out to act as observers, e whole affair went off with a snap and bang that aroused l enthusiasm. It had been planned to have ten cars eam, but this match being a new thing with the Chicago ic Association, the cherry circles found it hard to get that cars. Six only came to the tape, and as the Chicago obile Club had ten members eager for the fray, the n rule was adopted and the automobile club penalized ths of a point as against a full point for the C. A. A. lts gave the victory to the Athletic association, its team incurring only 4 points penalization as against 732 for the obile club. The latter lost out through accidents early in ht. The match was over the Elgin-Aurora circuit, but the two teams got out of town W. A. Egermann in a er was put out by a broken axle, and, a little later, T. P. rson in a Studebaker, skidded on Milwaukee avenue and a wheel. Egermann telephoned for another car and the circuit, while Henderson secured a new wheel and aught up with the procession. The others went along nly minor mishaps, the most serious of which were a r adjustment, taking on water and motor stops. The of the judges was as follows:

Chicago Athletic Club.

Entrant and Car.	Score.
W. Ham, Locomobile	Perfect.
P. Knisely, Premier	Perfect.
J. Ireland, Stevens-Duryea	Perfect.
K. Cochrane, Stoddard-Dayton	Perfect.
W. Wentworth, Rambler	1 point.
K. Young, Thomas	3 points.
Total	4 points.

Chicago Automobile Club.

E. Nash, White	Perfect.
V. Gethre, Stevens-Duryea	Perfect.
Tarrant, Jr., Stoddard-Dayton	Perfect
L. Van Sickien, Apperson	Perfect.
Joll Shaffer, Stevens-Duryea	Perfect.
I. Purdy, White	Perfect.
. O'Hare, Thomas	1.8 points.
. Gregory, Thomas Forty	15 points.
. Henderson, Studebaker	115.2 points.
A. Egermann, Rambler	600 points.
Total	732 points.

ules were easy, calling for the contestants to make a or stop run, with penalties for taking on fuel or water repairs or adjustments. Owners had to drive them- The running time averaged up about 15 miles an hour me was late at controls.

I CAROLINANS ORGANIZE CLUB AT RALEIGH.

B. N. C., Oct. 19.—The automobile enthusiasts of Ra- C., have decided that it would be to their benefit as he city's if they had some good permanent organization, well attended meeting the Raleigh Automobile Club ially launched with everything pointing toward success. iota of officers were elected and a suitable constitution aws adopted.

MARYLANDERS ELECT DR. ROWE AS PRESIDENT.

BALTIMORE, MD., Oct. 17.—In addition to electing officers for the ensuing year, the Automobile Club of Maryland, at its annual meeting, transacted other important business and determined upon what the members call a rejuvenation with the result that many suggestions for a busy winter were made. The officers elected were as follows:

President, Dr. H. M. Rowe; vice-president, D. C. Walker; treasurer, Ernest J. Knabe, Jr.; secretary, Frank W. Darling.

Board of Governors—James S. Reese, M. S. Hess, C. H. Millikin, A. A. Piper, B. B. Friedenwald, R. M. Norris, Dr. H. M. Rowe, D. C. Walker, Ernest J. Knabe, Jr., and Frank W. Darling. Osbourne I. Yellott was reelected counsel.

An important feature of the meeting was the report of the committee on good roads to the effect that the Baltimore County Commissioners had offered to give the club 800 sign-boards, 2 feet long by 8 inches wide, and furnish posts for the same, provided the club would paint them and place them in position at points along roads to guide autoists on touring trips. The offer of the commissioners was unanimously accepted. The committee announced that it had already decided upon the locations of 250 of these signs, which will be placed at crossroads and dangerous curves. Later on the club will make efforts to have the commissioners of other counties in the State co-operate with them for the purpose of having similar signs placed in the different counties.

One of the suggestions at the meeting was for a club publication. This paper will be issued for the first time next month and will be known as the *Maryland Motorist*. Most of the reading will be of matter in which Maryland motorists are interested. Frank W. Darling, secretary of the club, is chairman of the committee in charge of the publication.

It was also decided to hold a hill-climbing or a non-stop, sealed-bonnet contest in the near future, while it was also proposed to hold an annual endurance contest.

A. C. OF PHILADELPHIA ANNUAL FOR BRAZIER.

PHILADELPHIA, Oct. 19.—The seventh annual Brazier Cup contest of the Automobile Club of Philadelphia will be held Saturday, October 31, over a roundabout course of about 65 miles—via Lonsdowne, Alden and Swarthmore to Media; via Newton Square and Devon to Valley Forge; thence through Bridgeport, Norristown, Centre Square, Antler, and Chestnut Hill to the Racquet Club in this city. The object of the run will be to keep as closely as possible to the legal speed limit, and the committee in charge has already gone over the ground and decided on a secret minimum, the car coming closest thereto being awarded the cup. The number and variations in the speed limits of townships, villages, cities and open country make the computation quite intricate. Intermediate controls and checking stations will be established, and failure to arrive at either at the time calculated by the committee will mean additional penalties. It is expected that a score of cars will start.

ROAD RULES ADOPTED BY PENNSYLVANIA CLUB.

WILKINSBURG, PA., Oct. 19.—The committee on road rules of the Wilkinsburg Automobile Club has given a vast amount of thought to common-sense regulations governing automobile driving on the public roads. Herewith is the approved report of the committee, and the result of its labors will undoubtedly be interesting to many other clubs:

First.—When passing vehicles going in the opposite direction, keep to your right, and when passing those going in the same direction keep to your left-hand side of the road.

Second.—Speed on heavy descending grades should not exceed 15 miles per hour. Brakes should be tested at top of grade.

Speed elsswhsrs always under control; this may bs 4 or 40 miiss psr honr, depending on road and traffic conditions.

Third.—Run slow on a descending grads when passing a car or heavily loaded team ascsnding, giving them the grsatsr right of way. When passing cars on a dusty road, run slowly to prevent dust obstructing the view of the road.

Fourth.—Always sound your horn befors passing a vehicle to give timely warning of your intention to pass.

Fifth.—Do not open your muffler when running on streets where the noise would bs objsctionable to residents.

Sixth.—Approach street or railway crossings under perfsct control, prepared to stop if necessary—"Stop, Look and Listen" before crossing steam railroads.

Seventh.—Approach a horss under psrfect control, prepared to stop if necessary to assist in gstting a timid animal safely past.

Eighth.—Approach curves where view is obstructed under perfect control, expecting to meet a car, keeping well to the right-hand side of the road, sounding the horn frsquently to give warning to approaching vehicles.

Ninth.—When passing farm houses whers poultry ars likely to be on the road, run slowly and give them a chance to get out of the way. Should your car kill any, stop and settle with the owner.

Tenth.—Never pass an nutomobils disabled without stopping ano offering assistance. Every car should carry a manila rope 25 feet long and three-quarters of an inch thick for emergency use.

Eleventh.—Upon observing broken bottiss or glass, barbsd wire or other tirs-destroying material, maliciously placed on the road, stop and remove them. If for epecial reasons a stop cannot bs made, then notify approaching cars of the danger.

Twelfth.—Upon discovering dangerous places in the road, such as holes, land or rock slides, fallen trees, etc., notify the nearsst farm or other house, also ths first hotel stopped at, with the request that motorists bs notified.

Thirteenth.—Light your lamps befors it is quite dark, and when standing on the road after dark bs particular that your front lights show in ths direction of traffic.

Fourteenth.—A continuous sounding of ths horn will be known as a distress signal, and whsn heard by motorists should be quickly respondsd to.

A NEW CLUBHOUSE FOR WILKES-BARRE.

WILKES-BARRE, PA., Oct. 19.—At a meeting of the Wilkes-Barre Automobile Club many things were taken up which are of interest to automobile owners in general. The most important were the plans for a new clubhouse as drawn up by President Lee, who presided at the meeting. He took up the many advantages to be derived from having an up-to-date building of their own, both to the members and their visitors. The results of the work of the committee on roads improvement was shown in the many highways which are either improved or entirely reconstructed in the vicinity of the city; the recent decision of the grand jury, declaring the bridges across the Susquehanna free bridges; and the movement on foot to have a state road to the Delaware Water Gap. The plans for financing the new clubhouse were discussed, and the following committee appointed to take charge of the project: George F. Lee, A. P. Keifer, P. R. Bevan, Charles Bertels, Frank Scouton, and C. F. Huber.

In regard to the hill climbing contest for next year, all members were unanimous in the opinion that everything possible should be done to make it even more of a feature than ever before; in fact, the idea met with great favor of publishing a small pamphlet to be distributed at the shows this winter, containing views of the previous contests, together with a description of Wilkes-Barre and vicinity, and how to get here over the new roads now in course of construction.

MONTREAL AUTOISTS COMMEND AUTHORITIES.

MONTREAL, CAN., Oct. 19.—At a meeting of the directors of the Automobile Club of Canada, held last week, the following resolution was adopted: "Be it resolved, that the president and directors personally, as well as on behalf of the members of the club, desire to congratulate the chairman and members of the road committee of the city of Montreal for the good work which has been performed in repairing and paving the strects of our city during the past season, and express the hope that the committee will be enabled to compete and maintain the good work accomplished."

At the same meeting reports from the various municipalities where oil had been placed on the roads were read, and the directors are much pleased with the results thus far obtained. The placing of oil on the roads not only abates the dust nuisance but preserves the roads, and will cause good macadam roads to last much longer. It is the intention of the club to place oil on several other good stretches of roadway during the early part of next season.

DELAWARE ELECTS SATTERTHWAITE.

WILMINGTON, DEL., Oct. 19.—A definite move for the marking of public road intersections was taken last night at the annual meeting of the Delaware Automobile Association, held in this city, and it was learned that the association is to have the co-operation of some of the turnpike companies. The Kennett Turnpike Company informed the association that it had procured the signs for its road and was preparing to have them put up. Delaware has been lacking in this matter in the past.

The subject of uniform and reasonable toll rates was also considered, the matter being left for adjustment with the incoming officers. The association is affiliated with the Allied Automobile Clubs of Philadelphia.

The following officers were elected for a year: President, John J. Satterthwaite; vice-president, J. Danforth Bush; secretary, Charles G. Guyer; treasurer, William Staniar; executive committee, Joseph Bancroft, Remsen C. Bernard, John B. Bird. Frank S. Garrett, and William F. Sellerd.

The association now has 140 members, the largest number in its history, and is in better financial shape than ever before.

WHAT ONE PENNSYLVANIA CLUB HAS DONE.

MEDIA, PA., Oct. 19.—To-morrow night will be celebrated the second anniversary of the formation of the Automobile Club of Delaware County, whose history of accomplishment, considering its extreme youth, is remarkable. Organized in October, 1906, with 48 members, it now has 220 on the roll, with numerous additions each month. From the start it has worked for the improvement of roads, the passage of favorable automobile legislation in county and town, the stoppage of speeding, the defense of autoists generally against illegal arrest and fines, and in numerous other ways. In two years it has made Delaware county an ideal motoring ground, and it is now engaged in urging and assisting financially in the improvement of the old Baltimore pike. The celebration to-morrow night will take the form of a banquet, which will be preceded by the annual election of officers.

STATE ORGANIZATION FOR MONTANA.

BUTTE, MONT., Oct. 16.—Last week a meeting of representatives from the principal automobile clubs of this State was held at Helena for the purpose of forming a State organization. All the delegates were enthusiastic for a State body which can co-operate with the American Automobile Association for the improvements of the roads, fair legislation and a better understanding of the automobile generally. E. C. Largey, of the Butte club, was unanimously elected president of the new organization, and returned home full of the plans which it is proposed to carry out for the benefit of the autoist.

ORGANIZING OF CLUBS IN MISSISSIPPI.

NATCHEZ, MISS., Oct. 17.—Under the leadership of Robert B. Bridge the automobile owners of Natchez have organized the Natchez Automobile Club. At the first meeting last week the following officers were elected: President, S. H. Lowenburg; vice-president, S. H. L. Landen; secretary and treasurer, W. H. Aikman. In other cities of the State automobile owners are getting together for other clubs.

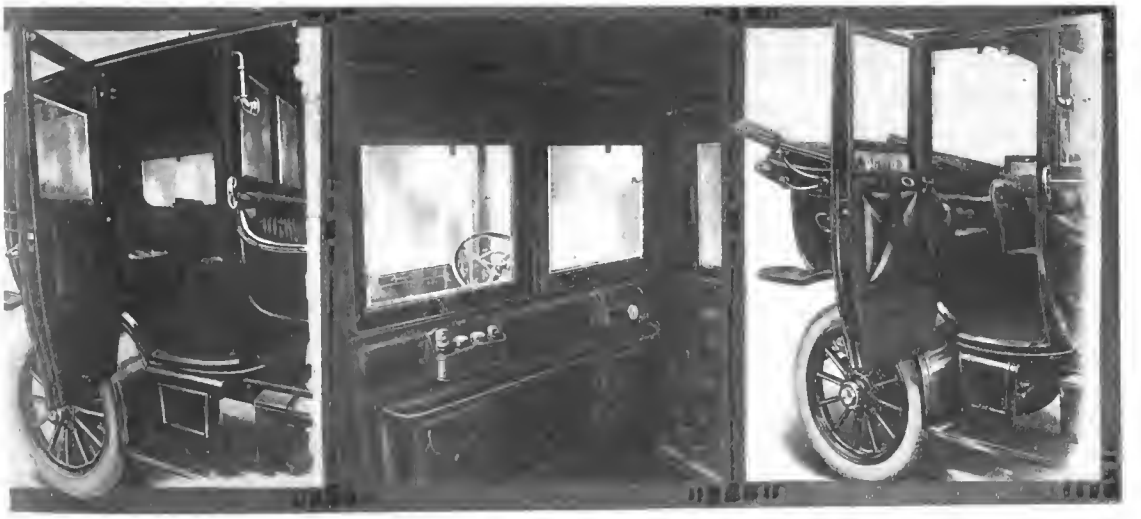
THE INCREASING UTILITY OF THE CLOSED CAR

ever widening demand for the enclosed car has stimulated manufacturers to produce artistic designs and furnishings limousine and landaulet types. The limousine appeals to liscriminating buyers because of its exclusiveness. Planned ilt on a plane of excellence, it appeals strongly to those ave a high regard for comfort and quiet richness and on. To those whose inclinations tend that way, there can greater satisfaction than to realize that a warm and com- c means of conveyance is at one's command, when prep- s are being made to leave home in attendance upon sional and business duties, and the elements of time and e become lessened, if not eliminated, from the mind.

, too, shopping may be easily and speedily accomplished ie greatest comfort, for ladies are conveyed to town and tore to store, and then home again in the shortest time e, and with every convenience at hand. Irrespective of r conditions the children must be taken to school, and not

features have been maintained, yet no new ideas have been set aside because they were new, nor have old features been discarded because they were old. The Peerless limousine offered for the season of 1909 shows clearly the survival of the fittest in motor car building. The tonneau is lighted by two small electric lights of four candle power each. An engagement book, clock, hand mirror and other smaller necessaries are provided, all of which go to complete the equipment of this carefully designed car.

Peerless cars for 1909 are larger, of higher power and more comfortable riding qualities than previous models. The mechanical changes are few and are in degree, not in kind. Each one has been demonstrated by long and careful tests to be a genuine improvement, making the car more simple, reliable, comfortable and more easily managed and cared for. The new body is designed to carry seven people comfortably. Two of the tonneau seats are of the folding types easily detachable and when removed the car is ideal for five passengers.



Showing the Fine Equipment of the Peerless Motor Car Company's Limousines and Landaulets.

d to sudden changes of temperature, and the limousine hly protects its occupants from all climatic conditions.

the sun shines and the days are warm and bright, the s may be dropped in front and at the sides, and thus advantages of the touring car are offered. The back s protection from dirt and dust, and the limousine, while y a car for city use, is thus transformed into an e means of country touring.

ndaulet has the increased advantages that the rear half p may be entirely thrown back, though still maintaining lvantages of the limousine, and the landaulet is becoming popular means of conveyance as the industry develops. tail has been considered with the view of making the limousine weather tight, and yet to allow for perfect n. The most luxurious upholstering is used, and no as been spared in its equipment. Entrance and egress is complished by means of two steps which are carefully to prevent clothes from becoming soiled. A speaking municates with the driver so that he may be directed liverting his attention from the road. The tonneau is enough to carry five people with the greatest degree of

construction of the new Peerless models shows no anges. Improvements take the form of a general of parts as well as their simplified relation. Reliable

NO REGISTRATION FOR UNCLE SAM'S AUTOS.

WASHINGTON, D. C., Oct. 17.—Quite recently a decision was rendered by the Comptroller of the Treasury to the effect that the Federal Government need not pay the District of Columbia authorities for automobile licenses for the numerous automobiles used by the various branches of the Government. This decision has been upheld by the corporation counsel, who likewise holds that automobiles owned by the Federal Government are not subject to a tax by the District government. The latter official has advised the District Commissioners to take no issue on their right to require an official of the United States as "owner" of an automobile to pay the sum of $2 for a license. "I am of the opinion," says the corporation counsel, "that the word 'owner' as used in the present automobile regulations does not include the United States."

The question arose when a bill was sent to the disbursing officer of one of the departments for $2 for a license for the official automobile used by the superintendent of the Capitol. There was some talk of taking the matter to the courts, as there was a possibility that the commissioners might have to issue the licenses without exacting the fee of $2. However, the decision of the corporation counsel has set the matter right by placing Uncle Sam's automobiles on the free list, and there will be no test of the constitutionality of the law requiring a fee of $2 for every license issued to an automobilist.

How the Packard Truck Was Utilized to Break Ground for Factory Addition.

Already possessing what is claimed to be the largest exclusive automobile factory in the world, the Packard Motor Car Company of Detroit is again enlarging the plant by several extensive additions. Several two-story buildings are nearly completed, and ground was broken last week for the first of a series of buildings to be erected on the opposite side of the boulevard from the factory, on a large tract of ground recently purchased by the company.

Between the Twin Cities and Duluth.—While scouting around the country looking over possible roads for the Glidden tour of next year, the Studebaker "Scout" car, with Donald J. McIntosh and "Pete" Estey, last week made a new record between the Twin Cities and Duluth, covering the 174 miles in 7 hours 32 minutes running time. Dr. C. E. Dutton, chairman of the tours and contests committee of the Minneapolis Automobile Club, and R. E. Tucker, automobile editor of the Minneapolis *Tribune*, were in the car and made a careful log of the trip. All kinds of roads were encountered and the record of 7 hours 32 minutes shows that some fast driving was done by McIntosh, who has something of a record as a "speed peddler." Sand predominated, in some places being six and seven inches deep. There are several stretches of corduroy road, some sharp hills with sand, and about fifty miles of the distance is good turnpike where the time can be made. The hotel accommodations in the Twin Cities and Duluth are ample, and everything considered the Glidden tourists would be given a cordial reception in the Northwest.

Lubrication for Racing Cars.—W. T. Kincaid, representing A. W. Harris Oil Company, Providence, R. I., who was in New York attending the Sweepstakes races, where he furnished a number of cars which made a good showing in the different events, including two winners, says that his company is very proud of the record made by Harris oil in this year's racing, giving the following noteworthy performances: The road races at Savannah, Briarcliff and Lowell; Motor Parkway Sweepstakes, where the Buick and Isotta both won their events; the last 24-hour race at Brighton Beach, in which the Simplex made a new record; the 24-hour race at Milwaukee, won by the Locomobile, with a Mitchell second; Bridgeport hill climb; 100-mile stock car race at Elkwood Park, and Ralph De Palma's car, which made new records at Providence on October. 10.

Matheson Annual Meeting.—At the annual meeting of the stockholders of the Matheson Motor Car Company, held at Wilkesbarre last week, the withdrawal of Charles W. Matheson from the presidency to assume the presidency of its selling company, the Matheson Automobile Company, necessitated the election of a new president, Colonel Asher Miner being chosen to succeed him. J. W. Hollenbeck was elected vice-president, Frank Matheson was again chosen as secretary and general manager, R. Nelson Bennett was re-elected treasurer and Daniel C. Mackay, assistant treasurer. The list of directors is the same for this year as for last, except that John C. Bridgman, of Wilkes-Barre, Pa., and E. S. Fretz, of Pottstown, Pa., were elected to fill the vacancies caused by the withdrawal of the Palmers of New York City. The list of directors now includes: J. W. Hollenbeck, I. M. Thomas, John A. Turner, Asher Miner, W. C. Shepard, B. Nelson Bennett, W. H. Son, Frank Matheson, Charles W. Matheson, John C. Bridgman and E. S. Fretz.

A Successful Mountain Trip.—What proved to be a thoroughly enjoyable trip, as well as a strenuous test for the car, was recently completed by Richard M. Shaffer of the Shaffer Manufacturing Company, Baltimore, Md. The tour was through the mountains of West Virginia, Maryland and Virginia, where the road conditions at times were not all that could have been wished for, in fact between Hancock and Cumberland, where the route passed over five mountains, the roads were so stony as to be almost impassable. On the return trip between Winchester, Va., and Berkeley Springs, W. Va., the sand at times was the worst ever encountered by Mr. Shaffer. In all he covered about fifteen hundred miles, using a 1907 Pullman of 20-horsepower, with which he had no trouble, being lucky enough to escape without even a puncture.

A 1,600-Mile Road Test.—A sealed bonnet test of the new $1,600 Jackson car is to be made during a trip from Jackson, Mich., to Bangor, Me. The start will be made next Monday. The passenger list will embrace E. P. Blake, of Boston, New England distributor of the Jackson; Richard Palmer, of Sea Neck Park, N. J., and Dr. C. G. Percival, of New York, the company's publicity manager. Arrangements have been made for reception of the car by the four organizations of Philadelphia, Boston, Portland and Bangor. The idea is to have newspaper men in the car as checkers all the way from Jackson to the finish at Boston on November 1. A schedule averaging 200 miles per day has been framed up in the 1,600 mile trip.

A Story from the West.—Here is a story from out of the West, brought to Chicago by W. K. Cowan, Rambler representative for Thomas B. Jeffery & Co., Los Angeles, Cal.: Two California motorists, traveling in opposite directions, met in a collision on the public road. Both were thrown from their cars but neither was injured, though both cars were badly damaged. "I'm going to sue you for damages," cried one when he got his breath. "I'm going to sue you for damages," shouted the other, wiping the sand out of his eyes. "It was your fault," said one. "No, it was your fault," said the other. "Well, it will cost us $250 apiece to get our cars fixed," ventured one. "And it would cost us $1,000 apiece to bring suit," said the other. "In that case, let's shake hands and save $1,250 each." They did.

Mooers Building Taxicabs.—Louis P. Mooers has entered into the exclusive manufacture of taxicabs and town cars for the Cleveland Autocab Company, of Cleveland, which has established a large plant at Geneva, O., with capacity for a large number of cars. Mr. Mooers is well known to the automobile world as the designer of the Gordon Bennett Peerless racers and Barney Oldfield's Green Dragon. He was until recently the superintendent and designer of the Moon Motor Car Company of St. Louis.

One Agent's Good Scheme.—To create a profitable rivalry among his chauffeurs H. Bartol Brazier, Philadelphia agent for the Marmon car, has offered a gold watch to the chauffeur in his employ, or in that of an owner who stores at his garage, who can show the most economical operation for November. A similar contest last May was closely contested and was won by Ralph Green.

The Rome-Tourney Radiator Company, formerly known as the Long-Tourney Manufacturing Company, of Rome, N. Y., has changed its name for various reasons. The capacity of the plant has been tripled and the output for 1909 will reach 50,000 radiators. In addition a quick repair department has been provided, where the company will take care of any make sent in for that purpose.

A Large Tire Contract.—What is probably one of the largest tire contracts ever given to a tire company has just been made by the Ajax-Grieb Rubber Company, which has agreed to deliver to the Maxwell-Briscoe Motor Company 29,000 tires before July 1, 1909. These 7,250 sets will be used as standard equipment on Maxwells in 1909.

Pennsylvania's Tags.—Over 24,000 automobile tags have been issued by the Pennsylvania State Highway Department during the present year. The 1909 tags, which will be ready for delivery by December 15, will be white with black lettering. It is expected that nearly 30,000 of the new tags will be required.

IN AND ABOUT THE AGENCIES.

Stoddard-Dayton Agencies in South America.—Sigmund Krausz, who has been acting as a South American representative for the Dayton Motor Car Company, has established Stoddard-Dayton agencies in Havana, Rio de Janeiro, Montevideo and Buenos Ayres.

Mr. Krausz found that the European makers had a good foothold in South America, but he succeeded in convincing the dealers that the American car of today is a worthy competitor.

Rambler, New York City.—Manager Hutchinson, who has charge of the agency department of Thomas B. Jeffery & Co., while in New York recently completed arrangements for the establishment of a wholesale distributing house for the Rambler in the East. The upper floors of the building occupied by the local agents, Homan & Schultz, on Sixty-second street, near Broadway, will be utilized. The present agent will look after retail sales and retain its present territory.

Firestone Tires, Boston.—The Boston branch of the Firestone Tire and Rubber Company, which has been located at 9 Park square, has removed to 145 Columbus avenue, the store formerly located by the Rambler agency. Manager T. J. Glenn is making extensive alterations, which, when completed, will give the Firestone agency much larger quarters than heretofore.

Pope, Los Angeles, Cal.—The Pope interests in Los Angeles will be handled by the newly-formed William R. Ruess Automobile Company, situated at 1028 South Main street, after November 1. This company is making extensive improvements which when finished will give it one of the finest salesrooms and garages on the Pacific coast.

Pierce Arrow, Baltimore.—The Foss-Hughes Motor Car Company, agent for the Pierce cars in Philadelphia and vicinity, has established a branch in Baltimore, with temporary offices in the Equitable Building. Frederick E. Devlin will be in charge.

Franklin, Cleveland.—The Standard Automobile Company, agent for the Packard, has taken on the Franklin line for 1909. F. A. Stock, of the former Franklin agency, has accepted a position with the Standard company.

Grout, Philadelphia.—The Grout Automobile Company has recently closed a deal whereby the Stoyle Automobile Company, of 1521 Spring street, will act as Philadelphia agents.

American, Pittsburg.—The Pittsburg interests of the American Roadster will be looked after by P. C. Wood and R. G. Wood, who have opened salesrooms on Wood street.

Franklin, Greenville, S. C.—C. M. Wing, of Greenville, S. C., has taken the agency for the Franklin car, and will be located at his new garage on Buncombe street.

Diamond Tires, Seattle. — C. E. Mathewson, Pacific representative of the Diamond Rubber Company, is preparing to establish a branch at Seattle, Wash.

Baker Electric, Wilkinsburg, Pa.—The Wilkinsburg Auto Garage, located on Hay street, have secured the agency for the Baker Electric.

Overland, Boston. — Hereafter the Overland interests in Boston will be taken care of by J. M. Linscott.

PERSONAL TRADE MENTION.

E. Le Roy Pelletier, advertising manager for the E-M-F and Studebaker Automobile Companies, was in New York last week. Mr. Pelletier is making a tour of all the larger cities visiting the E-M-F representatives and Studebaker branch managers. His trip will not only take him through the South and East, but before he returns to headquarters again he will have visited Los Angeles, San Francisco, Portland and Seattle, besides a number of places along the northern route on his return from the West.

Frederic Coleman, for several years manager of the London branch of the White Company, arrived last Friday on the Mauretania for a short visit to this country. Mr. Coleman has been active in making the White steamer prominent in England, and on his arrival here spoke very optimistically of the outlook in the British Isles for the coming season.

Harold Stillman, who has been a prominent figure in the automobile trade in Philadelphia for some years, died at his home in Hartford, Conn., after a two-weeks' illness with typhoid fever, which turned into peritonitis toward the end. Mr. Stillman had been successively connected with the Mercedes, the Pennsylvania, and later the Foss-Hughes Company.

Olds to Become an Aviator.—Another convert to aerial navigation has been obtained in the person of R. E. Olds, president of the Reo Motor Car Company. He is scheduled to make a flight in company with Charles J. Glidden, at Springfield, Mass., on or about October 24.

F. B. Read, for the past four years with the selling department of the Springfield Metal Body Company, Springfield, has severed his connection to accept the position of assistant manager of H. J. Koehler Company, of Newark and New York City.

Arthur Holmes, assistant mechanical engineer for the H. H. Franklin Mfg. Co., who is visiting the Franklin agencies through the West, including the Pacific Coast States, sends word that the automobile business in that section is very active.

Thomas R. Roberts, who has been acting as assistant manager of the Philadelphia branch of Thomas B. Jeffery Company, has been made manager in place of William F. Smith, who has resigned.

Frank L. Kimball, who has been connected with the Chicago branch of the Autocar for some time, has gone with the Bird-Sykes Company, agents for the Matheson and Corbin in that city.

Charles W. Mears, of the Winton Motor Carriage Company, is making a tour of the East investigating the advertising situation at the different Winton branches.

C. W. Moody, who has had charge of the Pennsylvania Rubber Company branch at Cleveland, O., will hereafter be in charge of the Western territory, with headquarters at Chicago.

Fred McAllister, former automobile advertising manager of the New York *Sun*, has joined the motor car advertising department of the New York *Times*.

BUSINESS DIFFICULTIES.

Baker Company of New York.—The Baker Motor Vehicle Company of New York, doing business at 1788 Broadway, was last week forced into involuntary bankruptcy by the action of some of its creditors. This action had been anticipated for some time, in fact ever since a year ago, when the business formerly carried on by the C. B. Rice Company was reorganized and carried on by the new company in the hope of working out the debts which had been contracted under the old management. It was impossible for the company under the business conditions existing for the past year to operate at a profit and the creditors deemed it advisable to cause the liquidation of the company. This company has no relation to the Baker Motor Vehicle Company of Cleveland, except that it sells the cars made by the last mentioned company. As soon as the bankruptcy proceedings are ended it is expected that the business will be completely reorganized and carried on with new capital put into it. Liabilities are placed at $100,000 and assets from $20,000 to $30,000.

RECENT INCORPORATIONS.

Standard Universal Rim Company, Jersey City, N. J., to manufacture and deal in metal rims and parts. Capital $50,000. Incorporators: B. S. Mantz, J. R. Turner and S. A. Anderson.

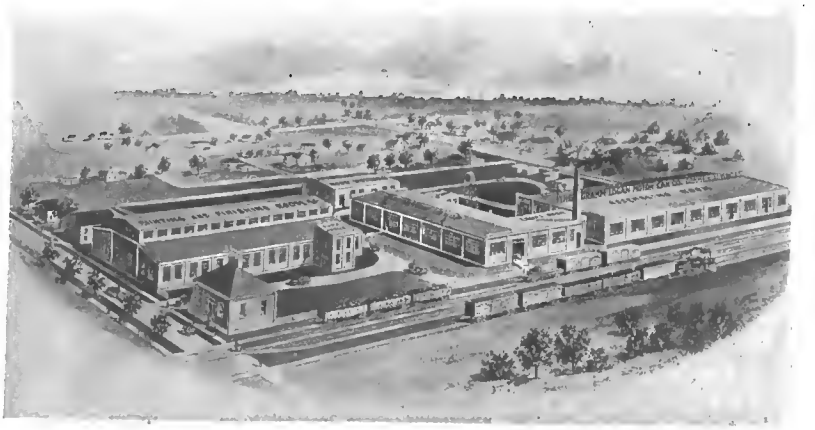
Rex Electric Company, of Kingston, N. Y., manufacturers of electrical lamps. Capital $600,000. Incorporators, E. M. Betts, C. J. Kleber and B. B. Maloney.

Champion Tire Company, Syracuse, N. Y.—Manufacture tires. Capital, $100,000. Incorporators, Q. C. Reed, E. O. Kinne and S. G. Schlachter.

Preston Fabric Tire Company, Buffalo.—Capital $100,000. Directors are Christian Wesp, M. R. Evans and J. F. Preston, of Buffalo.

Southern Tier Motor Company, Elmira, N. Y.—Capital, $25,000. Directors: G. N. Shoemaker, C. S. Satten and H. K. Crandall.

G. H. Pexley Company, Boston.—General automobile business. Capital $50,000. Charles H. Tebbetts, Marshfield, president.



New Factory of the Gramm-Logan Motor Car Company, Bowling Green, Ohio.

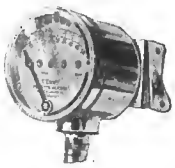
INFORMATION FOR AUTO USERS

Stewart Speedometers for 1909.—The Stewart & Clark Mfg. Co., of Chicago, maker of Stewart speedometers, announces that a number of attractive features have been added to the regular models, and that the line has been increased by two new models. A reduction in price in the 75 ninety-mile model to $50 is announced. Both this and the 90 model will have a new and unique trip recorder of three dials indicating the mileage in miles and tenths, with an automatic resetting device, different in construction to anything of the kind on the market. These models will be equipped with maximum speed hand. A feature of the mechanism operating the trip and maximum hand is the elimination of springs and other devices liable to derangement.

STEWART MODEL 4.

The new models are No. 11, at $25, and No. 12, at $15. The $25 model, which is of new construction, indicates speed from 0 to 60 miles and has a new trip recorder and resetting device. Owing to the indicator being mounted in the center of the dial, the scale is three times as long as is ordinarily used. The $15 model, which is the same in design as the $25 model of last season, has a 50 mile scale and 10,000 mile season odometer. It is three inches in diameter and has a number of refinements in construction, which its makers believe will insure satisfaction.

MODEL 11.



MODEL 12.

TWO NEW STEWART SPEEDOMETERS FOR 1909.

All models will be equipped with the Stewart & Clark flexible shaft and swivel joint and are guaranteed absolutely for five years.

New Rear Lamp.—A new rear light, known as Foy's patent automobile rear light, is being manufactured by Meisel Press & Mfg. Co., 944 Dorchester avenue, Boston, which has some special features. It is an electric lamp which fastens permanently to the rear of the car, and may be lighted by any ignition battery, bulbs being furnished for either 4-6 or 8 volt batteries. The globe is held in place by two spring terminals which, the makers claim, will prevent any possibility of the globe loosening or dropping out. As shown by the accompanying illustration, the light is placed horizontally and parallel with the back of the car, thus throwing the light well over the number plate, and through the ruby light, which is directly in front. The rear half of the lamp box is hinged to facilitate cleaning the silvered reflector. The number plate holder attached to the lamp is made so that it will take any size State number plate without the use of any tools, because of the spiral springs which hold the plate in place.

FOY AUTOMOBILE REAR LIGHT.

"Myhtib" Tire Overcoat and Inner Tube Patches.—The Myhtib Composition Company, of Hartford, Conn., is producing a preservative for the outer shoe or casing of tires which is of especial interest to automobile owners. Anyone familiar with rubber tires knows that they will deteriorate and lose their life if left standing unused for any length of time, the rubber being kept in much better condition if the tire is in use. The manufacturers of this new composition claim that when the "Myhtib" overcoating is used this loss of life will not take place. They especially recommend it for use when a car is jacked up for the winter, and also to dealers who carry cars in stock for two or three months with tires on before sold; also for keeping the extra tires carried on the car in the best condition. This "tire saver" comes in an outfit composed of a cake of "Myhtib" composition and a bottle of "Myhtib" preserver; the cake being melted and applied while hot.

TRADE-MARK OF THE MYHTIB PATCH.

This company is also making a tire patch which has the good qualities of being sold with the cement on in shape to be applied to the injured spot, and the consequent feature that the patch may be put on in three minutes. The patches are sold in one size only, 2¾x2⅜ inches, and are placed in boxes of five.

Oildag.—The Acheson Oildag Company, of Niagara Falls, N. Y., are manufacturing a mixture of deflocculated unctuous graphite and oil, which they claim will not only reduce the oil consumption, but increase the power of the engine and prevent pitting of valves when used according to their instructions. This mixture is in the form of a paste, and when mixed with the quantity of oil specified on the package it gives an amount of graphite content to the oil equal to .35 of one per cent. of its weight. This is the same as though you took one cubic inch of solid graphite, divided it into molecules, and mixed it with three gallons of oil. It is said that instead of the usual 200 miles per gallon of oil, as advised by a number of car builders, a machine using Oildag will do over 600 miles on one gallon of oil. Because of the graphite, which, as an impalpable powder, is carried by the exhaust and deposited on the metal surfaces, the claim is made that all future pitting is effectually prevented. The product is put up in three sizes of packages, the smallest enough for one gallon of oil, one for five gallons, and the largest for ten gallons.

Thomas Shock Absorber.—The shock absorber shown in the illustration is manufactured by the Buffalo Specialty Company, which has bought the plant of the Thomas Spring Works, Canisteo, N. Y., and transferred all the machinery, patterns, etc., to one of its Buffalo factories, where the manufacture of Thomas shock absorbers will be extensively carried on. A number of improvements have been incorporated into the device. Among the advantages claimed for this form of shock absorber might be mentioned the increased ability of the lever arm of the spring by the length of the lever arm to the point of application of the force. This same length of lever arm will reduce the periodicity of the oscillations. The makers point out that the shock absorbers afford the snubbing phenomenon during the period of reaction only. In this way the tendency to disrupt the spring leaves will be less, if not entirely eliminated, while the rebound, which is the matter to be considered, falls off to very comfortable proportions. The very fact that the periodicity of the oscillations would be reduced by the length of the lever arm tends to reduce the lateral rolling of the body, which in itself is an extremely important matter. Obviously this device should occupy an important nich by way of an accessory to the automobile, if it will reduce the rebound and more or less eliminate lateral rolling. It is not alone in the matter of spring breakages that these disagreeable factors have to be noted, but because the rack shock and the products thereof are by way of considerable increase in the cost of upkeep of the cars. The makers of this shock absorber claim that they very materially reduce the factor of upkeep.

AMERICA has at last come into her own. An American car, designed by an American, built by Americans in an American factory, of American material, and driven by an American, finally won America's classic contest in this the fourth year of the stubborn perseverance of Americans to place American cars on a speed level with the product of Europe.

The Vanderbilt Cup race of 1908 has been run and won by a Locomobile, designed by A. L. Riker, built

The Isotta, Lytle Driving, Which Finished In Second Place, With a Fine Record for Consistency.

y the Locomobile Company of America, and driven by George obertson, of New York, Saturday, October 24, over eleven laps f a 23.46 miles course, an out-and-out American combination volved a triumphant winner. The 258.06 miles, made up of Nasau county roads, except for some nine miles to the round of the ong Island Motor Parkway's cement stretch so far completed, as covered in 4:00:48 1-5. The fastest lap of the race, 20:17, an verage of 69.49 miles per hour, also was credited to the Locoobile. The average scored was 64.38 miles per hour, a new ecord for American roads, beating the previous best record f 64.25 miles, made by Herbert Lytle with the Isotta in the lotor Parkway Sweepstakes over the same course two weeks efore. More to the point, however, is that the result of the ace transfers not only an American record held by a foreign ar with an American driver, but also a hitherto best Vanderlt Cup average, scored by an out and out European combinaon, to an utterly American aggregation; for the Locomobile id Robertson also beat the 61.49 miles average scored by the arracq and Hemery in the 1905 race.

The average put up by the Locomobile and Robertson far utstripped the other records of this season's road races in this ountry, in addition to the Sweepstakes figures. Louis Strang, the triple-winning Isotta, averaged 50.70 miles at Savannah, 5.15 miles at Briarcliff, and 53.6 miles at Lowell.

The runner up Cup honors fell to the Isotta, hitherto unbeaten in any road race this year. With Herbert Lytle at the heel, this marvellous little racing craft finished in 4:02:38 2-5, ith an average of 63.88 miles per hour, but a fraction below s record performance in the Parkway Sweepstakes. It lost rst honors by but 1 min. 48 1-5 sec., putting up the closest ace in the history of American long-distance racing, surpassing ven the closeness of the memorable struggle between George eath and Albert Clement in the first Vanderbilt event.

Following Lytle's finish the crowd swarmed over the homeretch and was reported as also to have overrun the outlying ourse. Accordingly, Referee Vanderbilt called the race off s a precautionary measure of safety. Two pilots, however, readed their way through the maze of people and finished. hey were Walter Luttgen in W. K. Vanderbilt, Jr.'s, Merdes and "Jim" Florida in Locomobile No. 1. Unofficial but eliable timing gave 4:30:35 to Luttgen, who had crossed the ne unhampered. On the other hand Florida was hemmed in y the crowd and long delayed. There would seem to be no oubt of his having finished third. Allowing him three minutes or his delay, his time would be 4:28:10. Even had but two minutes' delay been granted him, he would still have finished ahead of the Mercedes pilot.

In enthusiasm and enormous attendance, it was the same old Vanderbilt Cup race. As a contest it was the best race ever run for the cup and the fiercest fought battle an American road race has ever produced. At the end of the seventh round, when 164.22 miles had been run, ten contestants were still fighting it out. Six of them at this point had yet winning chances, less than 15 minutes separating the leader from the tail-ender of the sextette. These ten were still running when the race ended.

George Robertson and Willie Haupt divided the honors of leadership, the Locomobile setting the pace for three rounds and then the Chadwick captured the running for the next three laps. The Locomobile had experienced slight delays, but they were sufficient to put it back in the ruck, so close was the contest among the leaders. Throughout the race the Isotta, running steadily and consistently from start to finish under Lytle's able pilotage, never lost its position in the pacemaking trio. Emile Stricker was also in frequent evidence in second and third place with Robert Graves's Mercedes until the tenth round, when the Mercedes entered by the cup donor got a grip on third place that was not shaken off until the last lap.

Robertson gained the lead in the seventh lap. The last five laps of the race was made up of an exciting duel between the Locomobile and the Isotta with from but two to four minutes separating them at any time. Robertson entered the last lap with but 3 min. 50 sec. to his credit over Lytle. Soon after word came that the Locomobile had stopped near Jericho on the backstretch. The grandstand was thrown into a turmoil of excitement and fairly seethed with suspense until a second megaphone bulletin told of his being off again with but a loss of about two minutes he had taken to replace a tire.

When Lytle and his Isotta had flashed by the stand first past the post, there followed minutes of anxious waiting and pent-up excitement that no race ever run in America before had ever called forth. Robertson had started ten minutes after Lytle and so had that margin in which to finish. Watches were out and anxious eyes shifted from them to the hill up the stretch. Five, six, seven minutes passed and no Robertson. Eight minutes, and a mighty shout went up as the big radiator of the Locomobile showed itself over the hilltop. It took but seconds for Robertson to dash down the homestretch and across the tape.

There were seconds of tense waiting for the final word from the timers' stand. It came and then there arose such a mighty whole-souled cheer and shout of triumph from the grandstand

and the thousands along tbe homestretch as no Vanderbilt Cup finish had ever called forth before. It was a mighty howl of glee and victory over America's first great road racing triumph. That stupendous cheer raised the curtain on a new era for America in international racing. Long patience and stubborn perseverance had at last won out and America was no longer a second-rater among the motor car racing nations of the world.

A wet course during the early stages of the race interfered somewhat with the speed attained by the contenders, otherwise the record would doubtless have been beaten by a broader margin than it was. It had rained for two hours before tbe start and the rain continued well into the second round.

Though the new course was less accessible than the old circuit and the location of the grandstand was remote and unfamiliar, as has been said above, the same old monster Vanderbilt Cup race crowd was in evidence. It probably did not equal the migbty throng that swamped Nassau county in 1906, but it reached the hundred thousands and maintained the prestige of the Vanderbilt Cup as America's greatest sporting event.

The race was utterly without fatalities and absolutely free from injuries to contestants beyond the singeing of Foxhall Keene's moustache during his attempt to put out a fire on his Mercedes. In fact, an accident apiece to cars and spectators was the sum total of casualties to onlookers. "Jim" Florida at the finish bumped into a touring car and damaged its radiator and in the mix-up a young man was thrown to the ground and had his leg broken.

To tell the unvarnished truth, the preparations that had been made to bandle the crowd and guard the course proved to be inadequate. The instinct of self-preservation did more to save the crowd from injury than did the private militia company that had been obtained or the Pinkerton men and the deputies that had been hired. There was an insufficient number of guards to make the wire fence barrier efficient. Hundreds scaled it and crowded those that had paid big prices for choice parking spaces along the homestretch. At the finish there was a rush of hundreds to the space in front of the grand and official stands. The supply pit hose pipes were brought into play with some momentary success, but they only checked the onrush temporarily and then the homestretch was again overrun, and Referee Vanderbilt was compelled for safety's sake to call tbe race off with the passing of the victor by the tape. There was also confusion anent the directions for reaching the parkway entrances and parking spaces. To most automobilists tbe region of the parkway and tbe location of the toll gates were unfamiliar. As these entrances had to be reached at night time, the route to them might have been indicated by guiding signs along the various roads of approach.

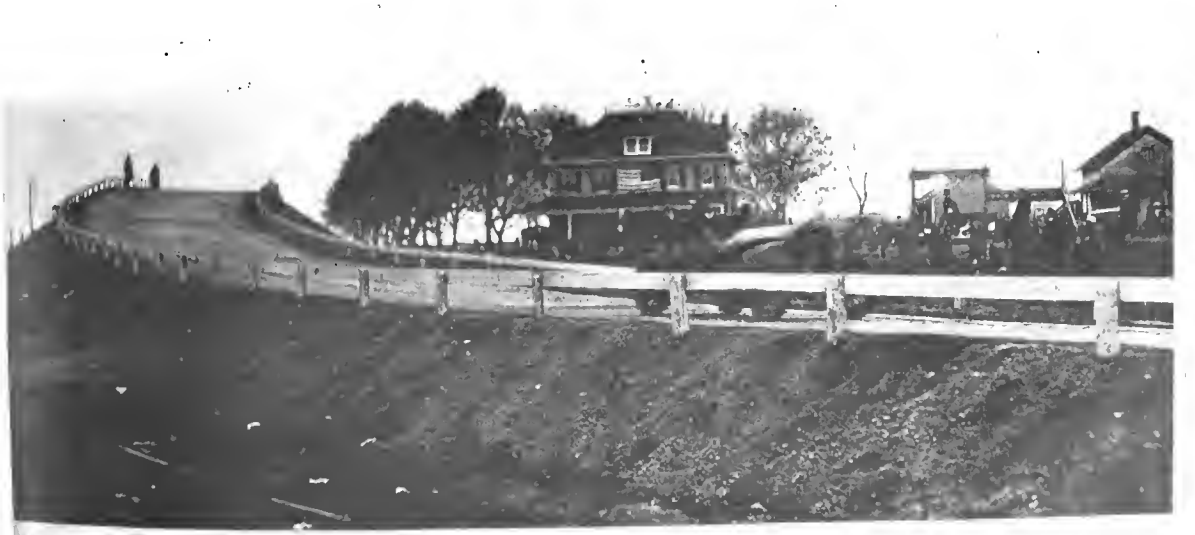
The arrangements for the conduct of the race itself and the convenience of officials and newspaper men, however, left no ground for complaint. The telegraph and telephone service on the press stand were pronounced adequate by the scores of newspaper men who had come from all sections of the country.

So far as crowds of foot passengers and numbers of automobiles went, the Vanderbilt Cup race of 1908, generally speaking, was not behind the average of its predecessors. No guesser witb any regard for truth and reason will attempt to assert that the throngs of people and cars equaled or even approached the attendance at the cup race of 1906, when transit facilities were swamped, and for a week before the race there was a steady pouring of machines into town from a radius of 500 miles.

The absence of the foreign makers and drivers from the contest resulted in a falling off of visitors from distant points, and, of course, of parties that toured to Long Island. Still all automobiledom in the metropolitan district was on band with its cars and that means the Greater New York and nearby Jersey furnished fully fifteen thousand machines. The daily newspaper guesses at the crowd hovered around 200,000, but that was, of course, mere guess work. There were fully 5,000 people in tbe grandstand and easily twice as many more packed along the homestretch in its immediate vicinity. There were thousands gathered at eacb of the towns and turns, and all around the circuit was a fringe of onlookers.

The road race goers of New York demand the novelty and adventure of an all night pilgrimage or encampment. They would not leave at 6 o'clock to see the start of the Sweepstakes at 9 o'clock. They welcomed the chance, however, to camp out all night on Long Island, or to start from the Rialto at midnight to see the Vanderbilt Cup race.

There were the same old familiar midnight scenes in the Broadway hotels and cafes, the late suppers, and the early breakfasts of the sporty element that was out for a racket and wanted to make sure of being properly keyed up. During the night two bridges and two ferry companies transported considerably over 4,000 cars. Add to these fully as many more that drove to the course from Broadway and then include the thousands of machines that had traveled to Long Island during the week, or had started earlier in the afternoon to put up at the various Nassau county hotels and farm houses, and the estimate of 15,000 cars to view the race would not seem to be an exaggeration.



Unofficially, the Third Car Was Undoubtedly No. 1 Locomobile, Driven by Florida, Which Ran Into Unruly Crowd Near Grandstand.

How the Race Was Contested Won, and Lost

IE weather-wise man at Washington had forecasted rain. But not a drop of it came during the long , in which the mechanics and motor sharks were with the final touches to their charges at the train- amps around the circuit, and there were hopes of a day and course for the race after all. But at half four o'clock, when the captains of the camps had about called from dreams of conquest and glory and night- s of punctured tires and magnetos that would furnish no the men on whose courage and skill the fate of each army was to depend, the dread drops began to fall and soon oped into a steady and what seemed a hopeless rain. There a hustling for rubber togs and a digging out of anti-skids. in the next hour the racing machines were en route to the e and the squads of tire tossers and oil jugglers to their s at the grandstand pits and the backstretch supply station. e first cup candidate to reach the starting line was George an in the Thomas, who got there at half past five o'clock. rs followed in quick succession and soon the number was ient for "Wag" to begin his task of getting them in their s in the starting line. Referee Vanderbilt and Chairman pson were also on hand in water-proof jackets, "knickers," puttees" to answer a hundred questions. Long before 6.21 ., the hour originally set for the start, the hustling starter he cup candidates lined up. Then came the announcement he start would be made at 6.30. The rain had ceased, but tening clouds dimmed the dawn. Even at this hour the and stand were well filled and black lines of intruding ands swarmed among the hundred automobiles to the east tretched in solid walls to the hill to the west a half a mile

the appointed hour grew near, the starter took his stand Locomobile No. 1. Charley Dieges and Sam Butler were with chronometer and note book. This time it was good ankee "ten, nine, eight," and not "dees, nuff, weat, set," n which "Wag" prided himself at former races, for this a bunch of American pilots unadulterated by any famous n mixture were to be sent away.

ven, six, five, four, three, two, go" and Jim Florida was off e great race of 1908 was on. There was applause as each ot away, but the first big cheer went to Lytle, who was to start. Ryall, Seymour, and Kilpatrick were dispatched er without incident. Then came a gap, for Pouget and the r were missing. En route to the course Mr. Whitney's d had the ill-luck to break its steering gear. Robertson, vorite, got away amid a mighty roar of encouragement and ishing. Hardly less of a demonstration started for Strang, was nipped in the bud by the inability of his mechanic to the Renault. There was a scurrying of camp followers rescue, a lifting of the bonnet, and further desperate crank- it still the stubborn spark could not be coaxed into life. time for the next "get-away" and the referee hastened to with willing shoulder to push the car to the side of the

Magneto trouble had been its undoing. During Strang's e in town the evening before, so the story goes, a new o had been put in. At the start its interrupter had panned fective and refuse to work. Finally, in despair the car shed back to the Renault pit. Twenty-eight minutes later it was gotten going at last and Strang started with a hopeless half hour handicap to make up. Strang and La Croix are popular and the tardy luckless Renault that suffered misfortune through accidents in both the Brighton Beach races got a cheer of good fellowship.

First Lap (23.46 Miles).—With all the seventeen cars under way came a craning of necks up the stretch for the first car that should heave into sight. There was less than five minutes of waiting, for at 6.53.10 "Jim" Florida in the pacemaking Locomobile shot by, having completed the round in 23:10. Next Stricker in Mr. Graves's Car, the Jenatzy Mercedes having overhauled and passed the Dennison Knox, which had started second. "Willie" Haupt was also burning up the road with the Great Chadwick and had also gotten by the Knox. All the time Robertson was climbing up the steps of the racing ladder, and though Chevrolet, too, was hitting a hot pace with the Matheson and had started a minute a head of the Locomobile, it was cut down by the favorite. Word came from the backstretch that Mercedes No. 18 was afire, the gasoline having ignited. It was another case of bad luck for Foxhall Keene, who in 1905 race had banged into a telegraph pole on the hairpin turn. He finally extinguished the flames and finished his first lap after the leaders had completed a couple of circuits.

Robertson completed his first round in 20:54 and in actual time was the leader in the race. As he finished his lap he slowed down to his pit to take on water and oil. It was feared from his seeking fuel so early that his engine was heating, but he was up and away again in less than two minutes. Already Robertson had gathered a margin of but a couple of seconds less than a minute on his nearest pursuer, the Isotta. Lytle and Haupt had had a neck and neck race for the place, the former capturing it by a second. They were being chased by Chevrolet and Salzman less than fifteen seconds behind them, the Thomas leading the Matheson by but fire seconds. Florida, Patschke, and Luttgen followed in order. The field was running well, only Keene have encountered any obstacle. Despite the slippery going, the leading trio were running among the records, Robertson with an average of 67:3, and Lytle at a 64:50 miles rate.

Second Lap (46.92 Miles).—The speed honors of the second round fell to Haupt and Lytle. The Chadwick by a lap in 21:29 made up the one second lead and gained 4 seconds besides on the Isotta. Stricker was making a splendid run in the Mercedes and put up a 21:58 lap to his credit. Despite his stop for water, which came out of the second lap, Robertson had spurted so hard that his gross for the round showed 22:15, and he still held the lead by a margin of 15 seconds. Florida, too, was well holding up his end of the Locomobile plank in fifth place, and Salzman and the Thomas hung stubbornly to the sixth. This sextette was running with a margin of but three minutes separating the first and last man. The indomitable Keene made a plucky run after he had extinguished the fire in his carbureter,

Vanderbilt Mercedes Ascending a "Hill" of the Parkway.

No. 2 Knox Overhauling No. 6 Grand Prix Thomas.

No. 12 Thomas Best of the Buffalo Trio.

No. 7 Matheson Which Had Its Share of Misfortune.

covering the second lap in 22:32. Strang had gotten the Renault going, but it was somewhat in the doldrums and no greater speed than 23:58 could be gotten out of it. In this round Chevrolet's fight in the Matheson was stopped for good by a cracked cylinder, and the Baltimore youth, Howard W. Gill, had his road racing début nipped in the bud by the gears of the Thomas refusing further to work. Chevrolet had made a fine first lap in 22:09, and the Matheson's downfall greatly disappointed those who had expected much from the new Matheson racer.

Third Lap (70.38 Miles).—It had rained a bit during the first lap, but had let up during the second. By the third round the sun, though veiled by mist, showed itself and set to work to dry out the course and made good progress. With his signal men informing him how close were the Isotta and the Chadwick at his heels, the daredevil in Robertson's make-up asserted itself and he put spurs to his motor steed. He had made laps in practice over a dry course in 20 minutes, but he still had a wet and slippery road ahead of him now. So daringly did he take the turns and so unerringly did he pilot his flyer down the straights along the country roads and over the "roller coaster" hills of the cement stretch, that he took unto himself the fastest lap in the race—a 23.46 mile round in 20:17, showing a rate of 69.6 miles per hour. Even at that rate of going the Chadwick in 21:27 was still but 25 seconds behind him, and the sure-footed Isotta less than two minutes to the bad. Stricker and Florida were holding stubbornly to fourth and fifth places, still pursued in order by Salzman and Luttgen. Both of the Knox machines were putting up an excellent race for stock cars of medium power, each gaining a place higher up in this round. In this circuit the Hotchkiss fell by the wayside with a broken clutch, and the Acme went out with broken gears. Kilpatrick had covered the first lap in 22:09, and Patschke had scored 23:23 for the same circuit.

Keene was well sustaining his reputation as America's crack amateur by his driving of his vetern Mercedes. He had made his second lap in 22:54. He bettered this in the third round by putting up a circuit in 22:18. There were mighty few professionals in the race beating the Long Island fox-hunter.

Fourth Lap (93.84 Miles).—In the fourth round Haupt put up the whirlwind lap that landed the Great Chadwick "six" in the lead and set the wise ones to wondering for this and two succeeding laps whether after all a dark horse might not spring a surprise on the much-touted trio of favorites and furnish the new American champion. Haupt had claimed for himself 20:40 in practice. Despite going that was not the best, he cut loose for fair and covered the course in 21:10. Lytle also got a few more notches of speed out of the Isotta and showed 22:04. In fact, the entire sextette of leaders ran this round at marvellous speed, Stricker scoring 22:23; Luttgen, 22:23, and Salzman, 22:31. Down among the luckless tail-enders Keene's light shone even more brightly than that of the vaunted leaders with a round in 22:10. All this hurrying and scurrying happened while Robertson was laid up at his pit at the grandstand looking after his tires. He put a new one on the rear wheel and shaped two others to his car for emergencies. It cost him a delay of over three minutes. This was enough, however, to put him into fourth place, so close were Haupt, Lytle, and Stricker at his heels. All this time Strang was plodding along way back in the ruck under a hopeless handicap of close to 30 minutes, incurred by his delay at the start. A burnt out clutch finally put him out of his misery and the race in this lap. The relentless law of compensation had gotten in its fine work at last on the winner of four straight road races and laid him low.

Fifth Lap (117.30 Miles).—Haupt continued his impressive run with the Chadwick and again in the fifth round scored the fastest time, 21:36. Further down the line Florida and Stricker were also putting in great licks of speed with rounds of 21:38 and 21:40. Lytle had slowed down to 23:28, and even Robertson with three cars still ahead of him was doing no better than 22:23. Stricker got by Lytle and Robertson failed to improve his position. In fact, Stricker's gain of a place was the

cylinder Chadwick, Haupt at Wheel, Which Made a Most Creditable Showing Until Ignition Troubles Put It Out of the Running.

hange in the whole time. Haupt was now but 27 seconds of Stricker, who led Lytle by 37 seconds. It was a race ir. Robertson had gained on Lytle, but was losing to the 'ick and Mr. Graves's car.

h Lap (140.70 Miles).—Robertson now began to real- danger and drove like a speed demon indeed. Covering urse in 20:30, he swept by Lytle and at the end of the as in second place, but with a margin of 1 min. 13 sec. ting him from the flying Chadwick. Lytle had spurted to 22 minutes flat and Stricker had fallen over three 's behind the flying trio of leaders. This quartette was g a wide field on the pursuing field.

:nth Lap (164.22 Miles).—At 9:07 word came that had stopped near Bethpage and that Lytle had passed him. ; time the Chadwick was not only leading in actual time, ading the pocession as well. He had some trouble with a 'hain, but it was a balky magneto that was his undoing. iere on, though he continued in the race, he was no longer :. He had put up a brilliant performance and demonstrated e Chadwick is a car to be reckoned with in the future in any company. The race had now become a duel between Robertson and Lytle. With the falling back of Haupt, the Locomobile had once more assumed the leadership. Putting up another lap in 20:36 as against Lytle's 22:05, he led the game Isotta that needed nothing but a wee bit of more power and speed by 2:09 at the end of the seventh round. With Haupt out, Stricker again got in the leading trio with Mr. Graves's car.

Eighth Lap (187.08 Miles).—The contest had now narrowed down to a match race between the Locomobile and the Isotta, though Stricker was some five minutes behind with the Mercedes, his only chance lying in an accident or more than a normal tire repair or fuel filling stop. Calamity came to Salzman in this round. The Thomas had been running smoothly and well scoring its laps in from 22:31 to 24:13. At the end of the preceding lap, which it finished in fourth place, it was tied up in front of the grandstand with an ill-fitting rim. It took Salzman fully 20 minutes to right it and this delay caused him a drop from fourth to sixth place. In this round Robertson pulled away a bit from Lytle and led him 3 min. 29 sec.

Ninth Lap (211.44 Miles).—Robertson slowed down a trifle

ien Strang Finally Got His Renault Into Action, It Accomplished Some Remarkably Fast Laps Before Its Finish.

in this lap to a 22:22 gait, and Lytle kept the Isotta at its limit, scoring 21:48. The Italian car showed the same even pace it has displayed in all its races. Up to this point its fastest lap had been done in 21:33 and its slowest in 23:42, a variation of but 2 min. 9 sec., fuel replenishment stops included.

"I just drove the Isotta at its best all the way," said Lytle, "and that was all I could do. The car could go no faster and its fastest was not fast enough to beat the big Locomobile."

Tenth Lap (234.60 Miles).—Once more Robertson quickened the pace of the Locomobile and pulled away a bit further from the Isotta, their respective circuits footing up 20:55 and 22:10. It was in tbis round that Graves lost his grip on third place with Mr. Graves's Mercedes. Stricker stopped at the Locust Grove Station to look after a leak that had developed in his radiator. When he lifted the hood he saw that the fan had come loose and run amuck, ripping a hole in the radiator, and that he was out of the race. This let Mr. Vanderbilt's Mercedes into third place, while the Salzman Thomas moved up into fourth position, closely pursued by Florida in the Locomobile.

The Finish (258.06 Miles).—Entering the last lap Robertson began his run over the homestretch with a margin of 4 min. 10 sec. Lytle, however, it must be remembered, had started ten minutes before Robertson and so was first to start the last round. Though the Locomobile had the race well and safely in hand, barring accidents, there was always the possibility of a stop for one cause or another. Robertson had been on his last circut some ten minutes when the announcement was bellowed by Peter Prunty through the megaphone that the Locomobile was off the road near Locust Grove. The excitement had hitherto been great. It became a tumult now. It raged for two minutes and then came the message that the favorite was on the road again and on his way. A great cheer went up. It seems that a skid had sent a tire to the bad. It took him 2 min. 10 sec. to unlimber a fresh tire and make the replacement.

Then, Lytle finished his run. All those at the finish, whose eyes were not glued to their watches, gazed eagerly up the stretch. Seven minutes passed and no Robertson. Eight minutes came and with it the Locomobile over the top of the hill, half a mile away. In less than 30 seconds he had flashed by the stand.

"Time! Time! Time!" yelled the crowd. It came quickly for once: "240 minutes 48 1-5 seconds." Robertson had won by 1 min. 48 1-5 sec. Thousands cheered themselves hoarse at America's first international road race victory. Then came the rush of the crowd that caused the ending of the race.

FOURTH RACE FOR THE VANDERBILT CUP, October 24, 1908—DISTANCE, 258.06 MILES; CIRCUIT, 23.46 MILES.

Viewed from a Technical Standpoint

E triumph of American automobile engineering and manufacturing is well evidenced by the fact that at the time the was officially called off, seven of the eleven American were running in good shape, whereas but two of the six gn machines were running. America had 63.6 of its cars ing; Europe had 33.3 of its racing creations still active e conflict. Of the eleven cars under American colors five ne designated old machines, their début in road racing g back to October, 1906, when they contested either in the ating or final Cup trials. Robertson's winning Locomobile, ell as the other driven by Florida, were built for the 1906 , but have been renovated since only to the extent of ing a selective type of gearset to take the place of the essive type that the Locomobile company was fitting in its ines a couple of years ago.

e two Thomas cars were the same seen two years ago, but d in appearance by the use of cylindrical transverse gasoanks in place of the type previously used in which the seat ncorporated with tank. There were other minor changes. ull's Matheson also was a two-year-old save in that not a mprovements had been added which were not of sufficient t to eradicate the characteristic lines it originally carried. ese five, three were running in good shape at the finish, one the winner and the other absolutely certain of third place ne officials succeeded in keeping the course clear and al- at least five cars to finish. The performance of these five s such as to warrant the inference that two years ago ca had solved to a large extent, in one or two factories st, the problem of building enduring racing cars even if t period our drivers were not the equal in experience of bred abroad.

six newly-constructed American machines gave a good t of themselves and four were running with the utmost ity at the finish, the Chadwick six, the two Knox es, and the Grand Prix Thomas being the quartette. At l of the sixth lap the Chadwick was leading the field by a of 13 seconds and running with great ease and regu- but lap seven was its Waterloo in which a couple of os went out of commission and necessitated running iles to the repair camp on three cylinders. In one mage distributor pin sheared off, the other short-circuited in nature. It took 56 minutes and 6 seconds to complete the l by that time its chance of winning was eliminated.

Grand Prix Thomas No. 8 driven by Seymour did not ast speed at any time, but evidenced regularity in the ips it completed.

ther two cars to keep in the running were the two Knox s, piloted respectively by Denison and Bourque; Denving finished nine laps and Bourque eight and reaching nd stand unofficially on the ninth. Bourque's machine ne distinction of being the lowest-powered racer on the , having a horsepower of 38 according to A. L. A. M. . In spite of this lack of power it negotiated laps in 24, 25, 37, 28, 31, and 32 minutes, a performance of commendable regularity. Denison's car is a higher-powered and faster machine and got a mark of 22:01 in the second lap, which proved to be its fastest. Both of these cars are alike in motor design, but differ in that the Denison machine is chain driven and Bourque's shaft. Both are characterized by motors having intake and exhaust valves carried side by side in the cylinder heads and with overhead rocker arm actuation.

It is regrettable that two of the new American cup contestants should have been forced to withdraw early in the race, the Acme six in the third lap and the Matheson in the second lap. The Acme started off on the first two rounds with a regularity that recalled its consistency at Savannah last Spring and critics started to look for a repetition of that performance. A long wait for the completion of lap three frosted the expectations and soon a special telephone message to the headquarters brought the information that one of the timing gears on the engine had broken and had incidentally wrecked the gear on the other camshaft. This necessitated immediate withdrawal. From a representative of the company it was learned that both of the camshaft gears are made of manganese bronze, a metal highly capable of withstanding the heaviest service, but it seems that the accident was simply one more case of racing luck—a misfortune which might have been avoided by a longer practice period. This car being the other six-cylinder contestant, much interest centered in its performance, and many were watching the working of the "sixes." But it shared misfortune with the Chadwick, though much more seriously, and the American public will have to wait for another performance before the "battle of the sixes" will be in more tangible form.

From a standpoint of tire wear, it is interesting to note that the Chadwick "six" in the eight laps it completed and in the unofficial ninth had not to make a single tire replacement, and a cursory examination of the tires as the car stood in front of the grand stand after the race was called off failed to discover any traces of extreme wear that would tend to indicate that a change would have been imperative before the end of the race had the machine been privileged to finish.

Immediately after the Cup race the officials of the Chadwick Engineering Works arranged for a public inspection of the car. For this purpose, the motor was dismantled in order that the dimensions and finish of the cylinders, as well as its other parts, could be examined. Through an unfortunate error it was stated in the table printed in the issue of THE AUTOMOBILE of October 22, that the motor was rated at 90 horsepower. By the A. L. A. M. official rating, its cylinder dimensions of 5-inch bore by 6-inch stroke show it to be but 60-horsepower, in view of which its performance during the four laps of the race prior to its delays through magneto trouble is all the more creditable. The makers state they will guarantee deliveries of duplicates of the Vanderbilt car, and will further guarantee them to be capable of the same endurance and speed.

The Chevrolet Matheson encountered hard luck on the second

Six-cylinder Acme Making a Spectacular Turn.

lap when the cracking of a cylinder worked its speedy elimination, although the car did not suffer any other troubles. This car is a four-cylinder machine in which are incorporated many of tbe principles of the 1909 cars which, it is said, will differ materially from the present machines. The car is a shaft-driven type and made a most favorable impression by its quick and easy getaway. This car uses a left side exhaust instead of the rigbt used on the old Matheson, and the value of such in a race is considerable in that there is much less danger of the smoke getting in the driver's face. In Ryall's Matheson the exhaust is taken out through the bonnet particularly high on the rigbt side and over the carbureter, and it was doubtless owing to this scheme that the car reached the grand stand on the last lap with flames sbooting from the mud apron. The initial trouble, and undoubted cause of the fire, came wben the driver hit a cement bridge too near tbe right side and at too high a pace, the result being a badly sprung rear axle at the right and the right rear wheel splayed at the bottom. This quick jerk, due to hitting the bridge, shot the gasoline upwards out of the carbureter, the vapor from which was quickly ignited because of the proximity of the hot exhaust pipes. To accentuate the danger was the fact that on this car the carbureter was slightly higher than ordinary, bringing it still closer to the exhaust. The fire had nothing to do, however, with the withdrawing of the car, as this was directly owing to a short-circuiting of the armature winding of the magneto.

Of the seventeen cars that started, thirteen were chain driven machines and four sbaft-driven, the latter class including Bourque's Knox, Strang's Renault, Chevrolet's Matheson, and the Hotchkiss. It is rather interesting to note that only one of tbese was running at the finish, the cause of their elimination, however, not being due to shaft drive. Of tbe chain-driven cars tbe Chadwick was the only one to make use of chain casings.

The five examples of low-tension make-and-break ignition were the two Locomobiles, and the three Mercedes cars and the Matheson. All otbers used jump spark with magnetos.

In motor design plenty of variation appeared. The Acme Knox and Grand Prix Tbomas serving as examples of individually cast cylinders, while practically all of tbe other cars had cylinders in twin castings. In the Locomobiles the intake valves are in tbe cylinder heads and operated by rocker arm, and in the two Vanderbilt Thomases the intakes are directly above the exhaust in valve chambers on the left side, and are opened tbrough rocker valve action. This is sufficient to show that the tendency is very strong in racing cars to locate one set of valves in the cylinder head and in some cases to put both sets in this position if room permits.

Replanishing at Grandstand, Car Baing the Iaotta.

The additional lubricating facilities for a racing car will always be an interesting factor, equally interesting as is the continuous pumping of oil to the crankcase by tbe mecbanics of many of the cars. The majority of them use large cylindrical oil tanks, some of which ahe carried between the gasoline tank in the seat, others on the dash—like the Hotchkiss, and one or two on tbe floor board in front of the seat, as used on one of the Mercedes. The large reciprocating oil pump in the footboard is with a majority of the racing cars an absolute necessity, and is an indication of the large quantities of oil necessary.

Many of the contestants showed inexperience by the small filling caps for the gasoline tanks as well as the oil tanks, and to these may be added the radiator caps. Undoubtedly the best example of large filling caps was Lytle's Isotta. When he stopped to take on supplies in front of the grand stand a funnel was handed of sufficient size, so that three 5-gallon gasoline cans could be dumped on end into it at once, while the mechanic held a fourth 5-gallon aloft and simultaneously emptied its contents into the funnel. By having each of the 5-gallon cans with specially large spouts, the work was done all the quicker. The oil arrangements for this car were such that it was but a matter of a few seconds to empty a 5-gallon can of oil into the oil tank. Robertson had mediumly good facilities, but lost time filling the radiator from a common garden hose at the starting of the second lap. Both of the Knox cars could have saved time by the use of long-leverage lifting jacks to raise the axle when making tire changes instead of using the common jack that the ordinary tourist carries in his kit.

Wheelbase Not, as Heretofore, a Factor.

The problem of wheelbase was not a determining factor in this year's race, as it was on the two occasions when the Darracq cars, piloted by Hemery and Wagner, carried off the trophy. Both of the Locombiles measured 110 inches from axle to axle, the Isotta is 118, and had the distinction of being the longest wheelbase machine in the contest. All three Mercedes measure 107 inches; Haupt's Chadwick, 112 inches; the Knoxes, 102 and 106 inches, respectively; and the Thomases, 104 and 112 inches. The banking of the turns is a factor which eliminates the wheelbase question to a considerable extent.

A commendable precaution in the form of a wire screen in front of the radiator was noticed on the Isotta and No. 3 Mercedes, the purport of these being to prevent injury to the radiator by stones thrown by other cars.

Because of the weight limit allowed in the contest, the wholesale drilling of frame parts and axles to reduce weigbt was not noticeable, except in one or two cases where particularly heavy cars had to reduce a good few hundred pounds. No. 4 Chadwick had the rear axle drilled throughout its entire length, but, in spite of this, had a good safety factor by reason of the original axle size. This car used a peculiar type of front semi-elliptic spring, in which tbe leaf wbich bolted to the spring hanger at the front end extended but half the length of the spring and bolted to a projection on the top of the spring shackle, giving an extra leaf in the front half of the spring, and one double in thickness for the remaining leaves. In conjunction with this sbock absorbers were used only in front. The majority of makers used shock absorbers in front and rear, and it was apparent that the Hartfords had by far the biggest following; the Renault car, however, being fitted with absorbers built at the home factory.

Mechanical Misfortunes of Some Contestants

AT the race is not always to the swift is quite as true of automobile racing as it is of other things, and nothing ht this out more strikingly than the mishaps which served ce some otherwise dangerous competitors *hors de combat* before things had settled down to a point where a winner be picked with anything like certainty. Contrary to precedent set by former occasions of the kind, when the great bulk contestants' misfortunes have been of a nature so trivial make them far more aggravating causes of defeat on that nt, all of the drivers' mishaps last Saturday were not small; petty in their origin, they led to things sufficiently serious ke it impossible to proceed.

bably in few events of classic importance that have been ince the automobile attained to a degree of development its design was no longer a matter of guesswork, has the g water proved such a prolific source of misfortune. Right Robertson, whose Locomobile lost two minutes on the first this account, down to Stricker and Keene of the Mercedes who were placed hopelessly out of the running at an early the range extended, and there were not a few others who the necessity of replenishing the radiator an imperative before they had gone very long. Well-meant efforts to against defeat from any cause whatever, coupled with a nervousness that was natural under the circumstances, was sible for this slight trouble on the part of Robertson's obile. The latter is equipped with a high-compression of large size, fitted with low-tension ignition and with no ession relief or other means for facilitating its starting. tle strength is required to turn it over, and for fear that those little things that cannot be guarded against on the gulated of motors might serve to delay his start and lose a crucial moment, Robertson ran the motor idle for quite ime before Florida in the No. 1 Locomobile was called to e. The result was that the motor ran pretty warm and it aporated no inconsiderable part of its normal allottment ing water by the time it got away. Robertson's time for t lap shows that fear of overheating did not delay him t many of the Locomobile supporters were in an agony ense, thinking that he might find it necessary to stop at some inaccessible place on the course to replenish the radiator. Fortunately, this did not happen, and the most serious result was the loss of a minute or two that had to be deducted from the following lap, due to the necessity of stopping at the stand to fill the radiator, but the manner in which the car was brought to its pit and the squirting hose made to deliver its output into the steaming radiator brought a cheer of admiration from the entire crowd. Quite in contrast with this, were the performances of those mechanics who leisurely removed the radiator cap and slowly poured the contents of a spout can into it.

But some of the drivers, whose misfortunes consisted of lack of sufficient cooling water, were not so fortunate. Seymour in the No. 8 Thomas Grand Prix car made no less than three stops at the Locust Grove repair station for the purpose of refilling the radiator, though like Robertson, his chief loss was in the time consumed. In the case of some of the others, it was a far more serious matter. In fact, two of the Mercedes entries, those handled by Foxhall Keene and Stricker, were retired on this account. When he returned to the stand on foot, in exactly the same manner as characterized his appearance during the second half of the 1906 Vanderbilt, and attired in the same clothes, Mr. Keene explained to Mr. Vanderbilt that a leaky radiator was the primary cause of his troubles, though he added that more real trouble had been condensed into an hour's running that he had ever been put to before in his entire automobiling experience. The gradual loss of the water caused the motor to overheat to a point where it was no longer safe to run it further, and everything on the motor was brought to such a high temperature that the oil-soaked ignition cables caught fire, effectively putting a quietus on the car's chances.

Stricker's case was even more serious. One of the fan blades came loose from its hub and, flying against the inner face of the honeycomb radiator, made several gashes in it, through which all the water escaped, so that when its condition was discovered, the motor could not be run until allowed to cool. The use of any water obtainable would have meant cracked cylinders, so that after the temperature had been lowered considerably by waiting, lubricating oil was resorted to in the attempt to locate the radiator leaks, but things were still so hot that the oil promptly caught

Hands Across the Sea—Locomobile and Mercedes.

But Robertson's Smile Is Happier Than That of Lytle.

fire, thus adding another to the list of competitors whose chances were ruined from this cause.

As a matter of fact, this most spectacular cause of a car's retirement was far more common than has ever been the case in any former event of the kind. In addition to the troubles of Keene's and Stricker's cars, which took place on the backstretch, the latter, near the Locust Grove repair station, Ryall's No. 7 Matheson suffered the same disaster, though from a different cause, and was driven several miles in a sheet of flame, until the grandstand was reached, where the fire was speedily put out. There it was learned that the fire originated from a gasoline leak. This mishap was further complicated by magneto trouble and ended Ryall's chances, although every effort was made to get the car in shape again.

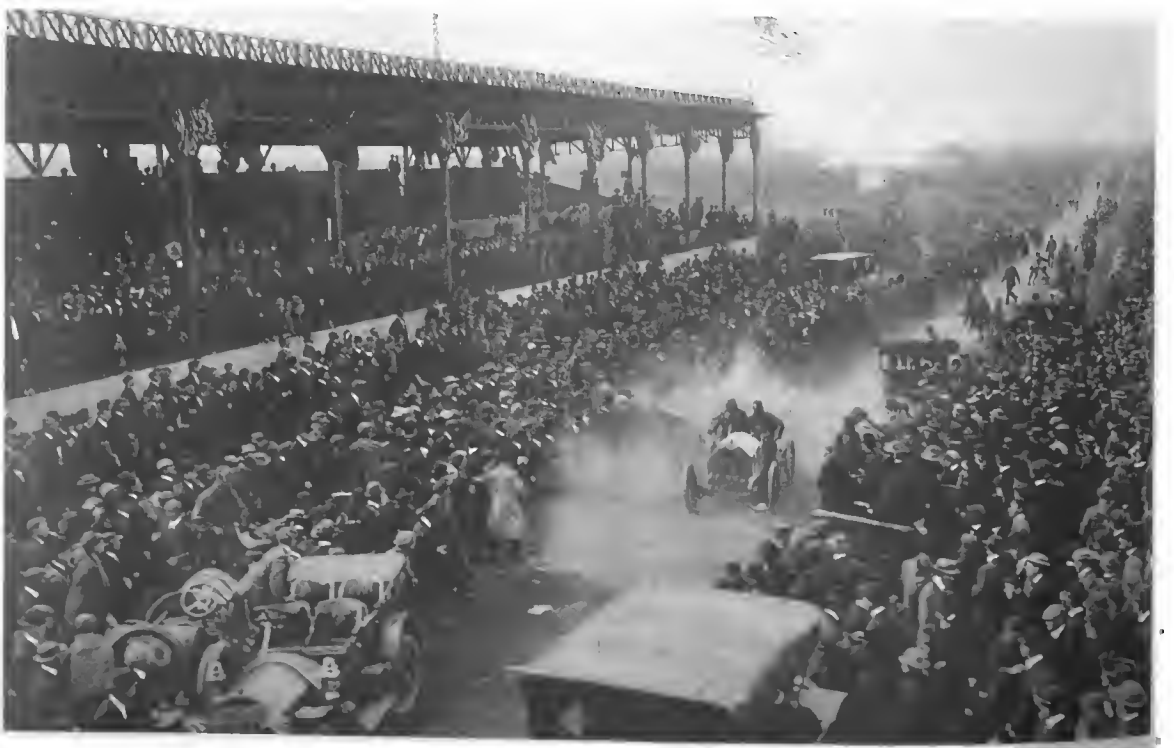
Just what had been responsible for the sudden and inexplicable elision of the Acme after having made two good laps, remained a mystery throughout the race. It had disappeared into its garage at Central Park and did not appear again after the second lap, but it was subsequently learned that the shearing of the pin holding the main timing gear on the crankshaft had put it hopelessly out of the running. Another of the long list of miscellaneous troubles that served to cut down the number of cars still running at the finish was the cracking of a cylinder on Chevrolet's Matheson, which was the first to be permanently retired. Doubtless the most disappointing case was that of the Brasier which broke its steering gear on the way to the start. Gill's Thomas provided the only case of gear trouble, while Salzman's No. 12 Thomas, which was third up to the seventh lap, had the misfortune to shear off four of the hub bolts holding the driving sprocket, replacing which cost fully 20 minutes and ended his fight for honors.

Of the things most to be dreaded by the racing driver, the petty troubles arising from ignition defections are probably feared more than any other, owing to the great loss of time they usually occasion to right them. They are generally trivial in themselves, but remedying them often means the waste of such an amount of precious time that ignition trouble is naturally the *bete noir* of every handler of the wheel.

It seemed particularly unfortunate that the Chadwick's highly creditable performance, which made Haupt a most likely winner right up to the end of the sixth lap, should have been spoiled on this account, as the consistency of the car's running and the great smoothness with which it maintained its lead were remarkable and formed the subject of universal comment at the stand. The tone of the big six-cylinder engine was scarcely a purr compared to the roar of the others, though it was reeling off the miles much faster than the majority of them, and the manner in which it was performing showed that a month's work could not have put a motor in more perfect running condition, as indeed its subsequent examination showed it to be, thus indicating that its defection was entirely due to the failure of the magneto. The Chadwick was the only car in the race that was equipped with two magnetos and independent wiring, but as ill-luck would have it, whatever was responsible for the defection of the one in use at the time, also appeared to affect the other, and even a third, which was taken as a replacement at the Locust Grove control, did not remedy matters entirely. Apart from this trouble, which caused Haupt to consume 50 minutes on the seventh lap, instead of his former average of about 21:25, the only stop was caused by a loose driving chain, which inspection showed did not require much attention and which ran the rest of the race as it was.

Strang's Renault was the first unfortunate to suffer from ignition trouble, due principally to the fact that the magneto fitted had only been put in place the night before, so that little or no time had been afforded in which to tune the car up with it on. Locating and remedying the trouble, which lay in the interruptor, cost Strang half an hour, and his chances were finally ended a few rounds later by the burning out of the clutch leather. Clutch troubles also ended the career of the big Hotchkiss early.

From an electrical point of view, the race was largely a battle of magnetos, as the contesting cars were fitted with the Bosch and Eisemann high tension magnetos in about the same proportions, the exceptions being the two Locomobiles, with their special low-tension magnetos, and the two Knox entries, which carried Splitdorf magnetos and a Connecticut four-unit dash coil and dry cells for starting.



Illustrates How the Crowd Swarmed on the Course After the Winning Locomobile Finished—Luttgen Is Worn

At the Repair Camps on the Turnpike

NOTWITHSTANDING the fact that the repair camp located at Locust Grove, about half way between Jericho and Woodbury, was fully equipped to meet almost any emergency in the nature of damage, and although each car had provided a separate stall manned by experts from the factories and supplied with every imaginable tool and extra part, there was but little call for any of these. The four racers to pass on the final round managed to dispense with the services of this available control entirely. The large crowd wbicb had congregated at this point was evidently of the opinion that there would be "something doing" in the line of record breaking repairs and replacements, and was only too eager to surround every car as it pulled up to its stand for gasoline, water, or oil.

The size and inquisitiveness of the crowd were a continual source of annoyance to the drivers who were forced to stop, when every second was precious, as was the case with two of the leading cars which met with minor accidents. There was small cause for wonder that several of the drivers became angry and made the air almost as blue with their vituperations as did the burning oil from the smoking motors.

Locust Grove is located near Syosset on the north side of the straight two-mile stretch of road between Collier's curve and Jackson's Corners, and as this is slightly down grade, it was along here that some of the greatest bursts of speed of the whole race were attained. The entrance to the repair stalls was about six inches deep in sand and dust, and one of the most spectacular features of the race was the sight of one of these powerful cars when it suddenly swerved off the main road and came ploughing through this soft road-bed, throwing the loose dirt in all directions. This served to attract the attention of the crowd to the unfortunate car, and by the time the tank cap could be unscrewed or the hood unstrapped, a mob twenty deep had surrounded the racer—there to remain until its attention could be attracted by the arrival at the control of another of the contestants. Of course many of the individuals endeavored to assist the drivers by handing them the necessary tools or parts, but in reality these little acts were more of a hindrance than a help, as it was one of the rules of the contest that the various supplies and accessories should be laid on the counter of the stall before which the car stopped and from there taken to the machine by either the driver or his mechanician.

While there was a total of eleven stops made for repairs, replacements, or replenishments by six different cars, but two of these halts had any direct bearing on the result of the race. The first car to pull up at the enclosure was the No. 7 Matheson on its second round. This car had lost the top nut of the right-hand steering knuckle, and although the car could be operated, high speeding with the steering mechanism in tbis condition was dangerous. An extra nut was soon found among the bag of spare parts carried on the car, and after a few turns with a monkey wrench, the car was again on its way, having spent about six minutes in repairing the damage. In the meantime, however, the Knox car No. 20 had passed on its second round and the Locomobile No. 1, the Chadwick No. 4, the Mercedes No. 3, and the Isotta No. 6 had all whizzed by, each on its third round.

While this stop of six minutes did not put the Matheson No. 7 hopelessly out of the race, its halt again on the fifth round was probably indirectly the cause of its burning a few minutes later fartber down the course. The motor bad been running badly on this fifth round, and when the stop was made for the second time, it was found that one of the needle valves had been lost, thereby causing the carbureter to form an imperfect mixture. While this needle valve was being replaced, opportunity was taken to replenish the gasoline, water, and oil tanks. The gasoline was poured in from five-gallon cubical cans which had a part of the cover torn off. This did not form a very good spout, and the result was that a large part of each can was spilled over the entire rear part of the car, and it appeared to the spectators as though even the seat was saturated with gasoline. Many who saw this shower batb of gasoline believe that this method of filling the tank was the direct cause of the fire which soon after burst out from that part of the car. Be that as it may, this contestant was effectually retired from the race soon after, but the speed with which the two replacements in question bad been made was the cause of many expressions of admiration from tbe crowd.

On his first round, Joe Seymour, who was driving the Thomas No. 8, passed slowly and called out to ask where the supply station was located. Much to the surprise of everyone, he did not stop then, but during his six subsequent rounds he balted three times—once for a new front tire and water, and twice for more water. In the meantime, it was expected with each round that Louis Strang in his unfortunate Renault would stop for repairs, but he managed to ignore the backstretch repair station until his car was finally forced to withdraw from the race.

The two little Knox cars were the center of admiring groups when they each stopped for minor adjustments—notwithstanding the fact that the force of their side exhausts was almost sufficient to blow a man over. No. 2 stopped on the ninth round to strap on a new extra tire, while No. 20 stopped on the fifth round to fill the crankcase with fresh oil. This latter car also stopped on the seventh round for a few seconds to replace a spark plug. When No. 20 left the enclosure after its first stop, it started out neck-and-neck with the Matheson No. 7, and the crowd was treated to the sight of an exciting brush down the road. This private race did not last long, however, as it was but a few minutes later that the Matheson caught fire.

The high hopes of the Chadwick adherents for their car were blasted on the seventh round by magneto troubles which developed. This car had started the race in fourth position and at the end of the third round had climbed to first place. It held tbis position for three rounds and was looked upon as a probable winner on account of its consistent running and the high speed of which it proved itself capable, when this trouble with the ignition was encountered. The fault was found to lie in the magneto, but as two sets of ignition apparatus were carried, the

uble was thought to be remedied easily. The second magneto, wever, also failed to work properly, and the car was forced make a stop at the repair station. Here an entirely new gneto was attached to the motor, wired up, and protected m the mud and oil by a rubber cover. At the same time that s was being done, the tanks were replenished with gasoline, er, and oil, and yet the entire delay did not occupy more than minutes. This stop, however, together with the delay on the d, destroyed all hopes of first place for the Chadwick, and eafter it was forced to content itself with seventh and eighth itions. This was one of the minor accidents which seriously cted the results of the race. This car stopped once again on ninth round for the purpose of tightening a loose chain, but on proceeded on its way again without taking the time to e the adjustment.

he one other car which had its position seriously affected by nnoying delay was Robert Graves' Mercedes No. 3, driven Emile Stricker. Although this was the same car which was y damaged in practice the preceeding week when it over- ed, its performance was one of the best of the morning, and racer had been holding second and third positions steadily en laps. Stricker had noticed that the motor had become what heated and he stopped at the repair station on his last or the purpose of refilling his water tank. The motor was d to be almost red-hot and the tank absolutely empty. On tigation, it was found that one of the fan blades had broken n its rapid revolution, had cut several holes in the honey- radiator, thus allowing all of the water to leak out. It was d that one of the cylinders might become cracked if cold were poured into this excessively hot circulating system, et a liquid of some kind was needed to determine the exact on of the leaks in the radiator. The danger of a cracked er was avoided by pouring thin oil instead of water into diator, but after a few minutes this produced an unexpected

When the oil came in contact with the hot cylinder walls, gradually vaporized and soon burst into flame which came the leaks in the circulating system. This set fire to the e, grease, and oil on the outside of the motor, and soon gine was a mass of flames. The fear of an explosion had ect of causing the crowd to scatter to a saft distance, and r and his mechanician were consequently given the elbow which they probably could not have obtained in any other The flames were soon extinguished with the aid of sand ew pieces of burlap in which some tires had been wrapped, may be supposed, this fire did not serve to cool the engine very much sooner, and these contestants were forced to sit idly by and watch the other cars pass on their way to the coveted finish line. Soon after the race was officially declared to be over, the unfortunate Mercedes had cooled sufficiently to allow the water tank to be filled, and it then joined the long line of homeward-bound spectators' cars and finished its eleventh lap at a much slower gait than had marked its progress for the ten preceeding rounds.

Although several of the racers suffered from tire trouble, but few of them had occasion to stop for accidents of this kind at the backstretch repair station. In fact, there were but two tire replacements made at this station, and one of these, that on the Mercedes No. 3, was not made until the car had practically been forced to retire from the race by reason of its hot motor. The other replacement was made on the extra Thomas entry, No. 8, but as Thomas honors were easily captured by No. 12, the tire trouble on the former car had no direct results on the effect of the race. The Knox No. 2 stopped once at the control for a new Fisk tire, but this was strapped on the rear with the other extra tires to be used in case of necessity and could scarcely be considered a tire replacement at the repair shop.

Many of the entrants displayed signals at this portion of the course in order that the drivers of their cars might be kept informed of their relative positions in the race. The Isotta No. 6, which ran a nip-and-tuck race with the winning Locomobile No. 16, had a large sign displayed at each round showing the difference in time between Lytle's and Robertson's running for that particular lap. Toward the last of the race, when it was a question of seconds as to which would prove the winner, the crowd was kept in a continual state of excitement by the figures on this board. These at no time showed Robertson to be more than three minutes in the lead, and when it was announced that he had encountered tire trouble on the last lap, after the Isotta had passed, much apprehension as to the outcome of the race was felt by his adherents. Robertson took every advantage of the straight course and down grade, however, and when he passed the control after having replaced his tires, it was apparent to everyone that his car was going much faster than any racer which had passed at any time during the contest.

While several of the cars were forced to retire on account of mechanical troubles, a remarkably large percentage of them were entirely free from difficulties and annoyances of this kind, and the preparations which had been made to cope with almost any kind of a breakdown were called into but little use, all of which speaks well for the constructors of the cars.

THERE was less tire trouble in the 1908 race than in any previous contest for the Vanderbilt Cup. It was a great day for the vindication of tires, to which in years gone by many failures to make a good showing have been laid by drivers. To the perfection of the tire equipment can undoubtedly be laid in large measure the generally good performance of the majority of cars that started, and also the tremendous speed of the leading machines. The rain that fell during the night preceding the eventful day made it necessary to change all of the tires on all of the racers at the pits in front of the grand stand, steel studded non-skid tires being substituted for the lighter and faster plain rubber tread shoes, and a pair of extra studded tires and rims being strapped on behind.

This occasioned a delay of half an hour in starting the race. Drivers also asserted that the use of the non-skid tires and the extra caution in driving that would have to be exercised on account of the slippery condition of the course would slow the running time from two to four minutes for each lap. Yet much of this disadvantage was made up in the general freedom from burst tires and from tires pulling off the rims. After the race started there were not more than half a dozen stops to change tires at the grandstand and hardly more than that number on the other parts of the course. Stoppages during the race were made in the great majority of cases to take on water and gasoline or because of some mechanical trouble.

Michelins and Diamonds Predominated in the Race.

The winning Locomobile, driven by Robertson, and the Isotta, driven by Lytle, which won second place, were fitted with Michelin tires. William K. Vanderbilt, Jr.'s, Mercedes, driven by Luttgen, which finished fourth, although not officially timed, also had Michelins, while the other Locomobile, driven by Florida, which finished third, was fitted with Diamond grip tires and demountable rims. The two Knox cars, which were still running when the race was called off, were fitted with Fisk tires. Matheson No. 7, driven by Ryall, and the Acme car, were equipped with Diamond non-skid tires. All the other machines not already mentioned were equipped with Michelins.

Robertson stopped at the grandstand on his fourth round and changed his two rear tires as a precautionary measure, fearing that they may have become strained in his terrifically fast third lap made in 20:17. In his last lap he skidded off the road on the "S" turn at Plainview and tore off the left rear tire, which had to be replaced before the car could be driven onto the course again. Two minutes and 10 seconds were lost at this point, cutting down his lead over Lytle in the Isotta from more than four minutes to less than two.

The remarkable showing made by the Isotta with its 60 horsepower as compared with the higher powered cars is to be attributed partly to the fact that it did not stop once for tire changes, so that its performance was very regular, the greatest variation in its eleven rounds being only 1 min. 54 sec. Mr. Vanderbilt's Mercedes changed one rear tire that blew out just in front of the grandstand. The Graves' Mercedes blew out a front tire that had to be replaced, and on the eleventh lap a stop was made on the back stretch to replace a front right tire. The Chadwick, which was leading throughout the first six laps, was reported to have stopped in the backstretch to adjust tires, but it was delayed principally by ignition troubles during that and the subsequent lap, which it completed before the race was officially declared off.

Florida, in Locomobile No. 1, which finished fourth, changed a right front tire at the grandstand at the end of the third round.

Both of the Knox cars, which were still running well when the race ended, stopped for tire changes. The 50-horsepower machine driven by Denison changed one front and one rear tire on account of wear to insure against a blowout, and the 40-horsepower Knox, driven by Bourque, made a change of the two rear tires at the end of the seventh lap, from the studded non-skids to plain tires, after the roads had partially dried, in order to make a gain in speed. It also had some trouble with one of the front tires. At the Locust Grove repair station it stopped for water and also strapped a fresh tire on the rear deck, but made no change there.

Seymour, in Thomas No. 8, stopped at the repair station at Locust Grove on the backstretch to take on water and to put a new tire on the left rear wheel, although to all appearances the tire seemed to be all right. Possibly it was worn and weakened.

The race was a gruelling test of tires throughout from the word "Go!" The instant the clutch was let in at the starting line in the gray dawn, streams of sparks flew from the wheels, due to the friction of the steel studs in the cement surface of the Parkway as the wheels spun around on the wet and muddy surface, unable instantly to overcome the inertia of the heavy cars. With nine miles of cement surface to grind over in each lap, the wear was severe, and on the narrow winding roads on the northeastern corner the stresses due to taking the turns at almost mile-a-minute speeds were tremendous. That mere rubber, cotton fabric, and leather treads could stand up at all under it is marvelous. Each car had two spare non-skid tires on demountable rims strapped on at the back, but only a few had occasion to make any use of them. It is probable that the notable lack of tire trouble was in some measure due to the rain and the use of the steel-studded leather tread shoes, which were better able to stand the grinding and strain than plain rubber tread tires would have been.

Tire Troubles Were a Minimum Race Factor.

Huge wheeled jacks of the kind used in the Grand Prix race in France were employed for making tire changes. They were wheeled under the axle until the upright yokes engaged the axles at an angle, then two men threw their combined weight on the long double handle and the tremendous leverage forced the wheels of the jack beyond the center of gravity underneath, lifting both wheels clear of the ground in one movement. Removable rims were used universally, so that not more than two minutes were required for any change of tires after the race started. No trouble with the rims and their fastenings was reported or appeared evident. In fact, in this race, for the first time in this classic event, tire troubles took a very subordinate place to troubles of another nature.

(Vanderbilt Cup Story Continued on Page 625)

WHAT IS THE BEST MOTOR TIMING?*

By LOUIS LACOIN.

IG conversant with the various questions of timing and e necessity therefor, we may now examine the diverse ıs which different designers have arrived at. In a table, e grouped together the timing of a number of well-known , the order of arrangement being that of the increasing

This procedure may appear to be the least logical, but it has the great advantage of progressing from the simple to the complicated. The lead given the exhaust, with which we will commence, is, in fact, the best known point in the timing of a motor, while the closing of the exhaust and the opening of the intake, times which frequently overlap, have values, which, according to different designers, vary by considerable margins.

The faster a motor turns, all other things being equal, the greater the amount of advance it is necessary to give the opening of its exhaust valve. It is a self-evident truth that if the speed of a motor be doubled, it travels twice as many degrees in the time necessary to lower the pressure. When considering different motors, as in this case, it is curious to note whether the same law has been observed, and the question may be put in terms of comparison for each one of the essentials of timing. It is this that has led us to adopt the classification of the motors by increasing speeds. So far as the exhaust is particularly concerned,

Point mort inferieur = lower dead center.
Retards a la fermeture de l'admission = lag of inlet valve closing.

read before the Society of Automobile Engineers at its Meeting, September 18-19, 1908. Translated from the "Omnia," by Charles B. Hayward.
he occasion for the present article was the appearance of nown as the Larrad for indicating proper timing.
he numbers following the names of the motors refer to erical classification in the table, page 606.

a strange fact is to be noted in that the slowest motor, *Ours* (1), has 55 degrees of advance, while the fastest, the *Sizaire et Naudin* (30), has but 44 degrees. The greatest advance, 62 degrees, is in the *Mutel* (11), which makes 1,300 r.p.m., and the least 30 degrees, is that of the *Vinot Deguingand*, which makes 1,500 r.p.m.

It is impossible to lay down an absolute law, but, generally speaking, it seems that the slowest motors shown in the table are those having the maximum lead. Whence this anomaly? Simply because it is essential in designing a fast motor, to allow large openings for the valves and large piping, and these may compensate for the diminution in the lead given the opening of the exhaust valve. It must be recognized, on the other hand, that the more the expansion is prolonged, the less advance is there possible, and the less noisily will the gases effect their escape. The Renault motors (28) perhaps owe to this fact their very silent running, as they have a lead of but 32 degrees. But it is well, before going further, to distinguish between the moment of opening and the manner in which it is done. We have here the sole data of the moment of opening, but the latter may be accomplished brusquely, somewhat like the pop of a champagne cork, or progressively, as where the same bottle is opened by slowly letting the gas escape round the cork. The second plan is less harsh, but slower than the former.

This comparison explains how we can have, side by side, and for identical motor speeds, the *Aries* (25), with a lead of 58 degrees given the opening of the exhaust, and the *Vinot Deguingand* (26), with but 30 degrees. The profile of their cams must be different. The dimensions of their valves may also differ, which is the reason why the advance of 52 degrees, fixed by the Larrad as the best for all motors, strikes us as somewhat exaggerated. However, this figure is not very far from the mean shown by 30 motors which we have examined, this mean being equal to 46 degrees, 20 minutes. A motor regulated according to the Larrad would generally have to increase the lead given the exhaust, which in itself facilitates an increase in the speed.

Lag Given the Inlet Valve.

The second column of the table gives the points chosen by various designers for the closing of the inlet valve. Some of them have adopted the dead center, but we have already given the reasons which cause us to hold a contrary opinion; one that is held by the majority of designers to-day. The *Motobloc* (5) and the *Farcot* (22) give but 10 degrees of lag, while the *Vinot Deguingand* (26) makes it 15 degrees, and a great number have hit upon close to 20 degrees as the proper amount, these being the *Peugeot* (Paris) (13), 18 degrees; *Ours* (1), *Cornilleau Sainte Beuve* (10), *Rochet Schneider* (19), *Eudel* (21), all four of which have 20 degrees exactly; *Mutel* (11), 21 degrees; *Rossel* (3), 23 degrees; *Brasier* (16), 25 degrees; *Renault* (28), 26 degrees. But those having a much greater degree of lag are also frequent, the *Hotchkiss* (7) having 33 degrees; *Berliet* (12), 38 degrees; *Panhard* (6), 40 degrees; *De Dion Bouton* (20), 45 degrees. The palm, however, if our information be correct, must be awarded the *Peugeot* (Beaulieu) (17), with a lag amounting to 58 degrees.

It is interesting to know how much reduction there is in the cylinder volume corresponding to such a great amount of lag in the closing of the inlet valve, and the sixth column of the table gives, for all the motors, the relation of the length of the connecting rod to the radius of the crank. This relation once known, permits of the drawing of a diagram indicating the position of the piston at each angle of the crank. The same result may, however, be arrived at through calculations. Thus we find that the 40-degree lag of the *Panhard* (6) corresponds to a displacement of the piston amounting to 18.7 per cent. of its stroke; the 45-degree lag of the *De Dion Bouton* (20) represents 23.9 per cent., while the 58 degrees given the inlet of the *Peugeot* amounts to 38.4 per cent. of its stroke. Thus the cylindrical volume of the *Panhard* cannot be utilized to a greater extent than 81.3 per cent., that of the *De Dion* 76.1, and the *Peugeot* but 61.6 per cent. In view of these figures, is it any wonder that one should be skeptical as to the ability of the theorist to give the power of a motor merely by inspecting its bore, and without even taking into consideration its stroke?

The motors that we have already cited would have with an equal bore, less power but a higher efficiency, were the inlet valve to be closed sooner. The *Larrad*, which allows but 17 degrees of lag, recommends a timing that would provide a probable increase in power but to the certain detriment of the fuel consumption. On the other hand, this change of regulation would not be unattended by further inconveniences. The capacity of the dead space, in the motors in question, has been calculated with relation to the useful cylinder volume; that is, taking the quantity of mixture that can be imprisoned in the latter. By closing the inlet valve sooner, will it be possible to shut in a greater volume of gas? This increased volume must, nevertheless, be compressed in the same dead space and its pressure

31	LARRAD DEVICE	52°	17°	—	22°	17°	....	....

The motors are arranged in this table in the order of their increasing speeds. The angles are figured in degrees, counting from the nearest dead center. "Var." means that the point of ignition may be advanced or retarded by the driver.

will exceed safe limits, so that after several months' running the inevitable carbon deposits that occur will give rise to auto ignition and the motor will knock. It would then be the wisest course to decrease the amount of lag given the closing of the inlet valve by the designer. But the advantages of the *Larrad*, on the other hand, are, in our humble opinion, well justified in the case of such motors as the *Labor* (14) and the *Luc Court* (15), in both of which the inlet valve is closed at the dead center. The compression of such motors must, in fact, have been calculated on the basis of their total cylinder volume, since when running slowly the cylinder would be almost full, while at an accelerated speed the degree of compression would diminish considerably, since the charge drawn in would not fill it to the same extent. But in giving 17 degrees of lag to the inlet, as recommended by the *Larrad*, the motor couple would be improved, and in consequence its power, so that its speed would be increased, and the motor would be capable of high speed, since the exhaust regulation recommended by the *Larrad* calls for a very early opening.

Concerning the Ignition Advance.

The third column of the table contains, more than anything else, the word "variable." Fourteen designers, however, have given their motors a fixed point of ignition, but this point is

being the same with all of them. Located 43 degrees
e of the dead center in the case of the *Cornilleau Sainte*
is but 20 degrees away from that point in the *Rochet-*
(19) and the *Aries* (25), so that the ignition advance
aid to vary more than 100 per cent. Here, again, we
lves confronted with an anomaly similar to that which
ointed out in the case of the exhaust lead. In a given
e more its speed is increased, the greater necessity
its for advancing the point of ignition. But the *Cor-*
otor, with 43 degrees of advance, turns at the rate of
r.p.m., while the *Aries,* with only 20 degrees, has a
1,500 r.p.m. The sparking point in the case of the
tor is probably located more centrally, and it may be
ble that the much faster rate of ignition comes from
y reduced dimensions of the motor itself. The mean
f the fixed ignition points represented in the table is
31 degrees, 15 minutes.

Exhaust Closing and Inlet Opening.

ve now arrived at the most delicate point of our an-
it concerning the closing of the exhaust valve and the
f the inlet. Theoretically, these two points should suc-
another, the exhaust closing at the upper dead center
nlet opening immediately afterward. We have already
reasons why we consider it advantageous to close the
alve but a few degrees beyond the dead center, and
also shown why the inlet can, without inconvenience,
an instant later. We have shown that the piston can-
the exhaust gases out of the cylinder except by com-
hem to a degree in excess of that existing in the ex-
ve port and manifold. This excess of pressure may
eeble, but it is indispensable. At the end of the pis-
ke, or upper dead center, this compression still exists,
how little it may be, so that if the exhaust valve be
d the inlet be opened at that instant, this pressure will
he entrance of the fresh gas; worse than that, the ex-
es will penetrate into the inlet manifold. The move-
this direction is not accentuated, because the piston
egins to aspirate, but it is none the less evil on that

r, such designers as the *Panhard* (6), *Aster* (18), *De*
, *Chenard Walcker* (23), and the *Darracq* (24) follow
which we condemn. On the contrary, such as the
, *Rossel* (3), *Gregoire* (4), *Brouhot* (9), *Peugeot*
13), *Brasier* (16), *Rochet-Schneider* (19), *Vinot De-*
(26) and *Sizaire et Naudin* (30), all close the exhaust
er dead center, the inlet opening with a lag ranging
degree in the case of the *Charron* (2) up to 20 de-
e *Brouhot* (9). But despite the imposing number of
dictors, we are still of the same opinion. It is upheld,
ewhat timidly, by the *Farcot* (22), for example, with
grees of lag respectively, and in a much more positive
the *Sultan* (27), with 14 and 22 degrees; by the
8), with 10 and 23 degrees, and, above all, by the
with 10 and 34 degrees. The *Mutel* (11) also opens
ve very late, giving it 26 degrees of lag, but it closes
valve even later, with 28 degrees past the dead center.
se two degrees, both of its valves are open at the
This is a curious method of regulation, but it is
ended by Larrad, who is of the opinion that the
open 17 degrees beyond the dead center, while the
uld not close until 22 degrees have been traversed,
later. This brings up three questions:
at point is it most advantageous to close the exhaust?
at point should the inlet be opened?
vantageous to close the exhaust before or after the

Point of Exhaust Valve Closing.

known that the closing of the exhaust valve should
piston has passed the upper dead center, but the
g given it should not be as great as that given the
closing of the inlet valve. Assuming that the excess pressure of the exhaust equals the depression during aspiration, the time necessary to complete the emptying of the cylinder will be proportional to the volume of gas contained in it. At the end of the admission the volume of gas contained in the cylinder is equal to the cylindrical volume, plus the dead space. Suppose that, for example, to be one litre, for a motor of which the cylindrical volume is ¾-litre, while the clearance has a capacity of ¼-litre. At the end of the exhaust stroke, the piston being at the upper end of its course, the volume of gas is only that of the dead space, or ¼ of what it was and it is accordingly natural to suppose that this excess of burned gas will escape four times faster than the fresh gas will begin to make its way into the cylinder. On the other hand, as the angles described by the crank are proportional to the time, it may be said that 20 degrees of lag given the opening of the inlet, to take a mean figure, should correspond approximately with 5 degrees of lag to the exhaust. In a previous article in *Omnia,* to which reference has already been made, the angles were 16 and 4 degrees. Those of the *Eudelin* (21), are 20 and 4; *Berliet* (12), 38 and 9, and the *Unic* (29), 40 and 10 degrees.

It is evident that no absolute rule can be given here as the losses of the charge in the exhaust manifold are not necessarily equal to those of the inlet. When the muffler is at all choked up, the back pressure may be very high and this consideration has led Larrad to recommend 22 degrees lag in the closing of the exhaust, and 17 degrees for the inlet. This is probably exaggerated, the *Renault* (28), giving 10 degrees to the exhaust and 26 to the inlet, while the *Motobloc* allows but 5 degrees to the former and 10 to the latter. These designers give the exhaust a lag falling between ½ and ⅛ that which they allow the inlet. That is, the lag in each case is proportionately greater than those mentioned, without, however, going as far as Larrad recommends.

It would seem to result from the above analysis that the proper amount of lag to give the exhaust lies between 5 and 10 degrees, and we incline toward the latter figure. Ten degrees represent an appreciable angle and the time required for the crank to turn through it is not negligible, and an important quantity of exhaust gas may escape, but the piston is still very close to the dead center after the crank has traversed it. With a stroke of 100 mm. (3.93 inches), the piston has traveled hut 1.5 mm., assuming that all the joints are free from play, but if the big end of the connecting rod has a little, to which must be added that of the upper end, there will be .2, .3 or even .5 mm. to subtract from that length, so that the piston will still be practically at the dead center when the exhaust closes.

(To be continued.)

NEW BOOKS FOR AUTOMOBILISTS.

"My Auto Book," by Walter Pulitzer, just from the press of the Outing Publishing Company, New York, is the most recent addition to the numerous collection of automobile touring memos, if such they can be dubbed, that has appeared in the past year or two. But it has the distinction of not only leaving out a great deal that might better have been omitted from many of its predecessors, but contains considerable in the shape of a running fire of comment, opposite each blank page, for the history of a trip, that will make it worth while, even if the memo pages are never soiled. The "comment" consists of jokes with a gasoline flavor; some of them good, and all of them appropriately illustrated. The author wisely refrains from telling the purchaser of the book how to run his car, and for that much at least, he should be thankful.

"Fly," a New Magazine of Aeronautics.—From the press of Lawson & Kelley, publishers, Betz building, Philadelphia, the initial number of *Fly,* a monthly magazine devoted to matters aeronautical, has made its appearance. Alfred W. Lawson, who is well known as an able writer and author, is the editor.

THE UTILITY OF AUTOMOBILE CLUTCHES

By THOS. J. FAY, E. E., President Society of Automobile Engineers

CONE clutches are not of the class in which a pound pressure of the spring means a pound pressure on the clutch face. The cone serves to multiply the pressure of the spring. In other words, there is a lever advantage in using the cone. Charles H. Schabinger, in the *Horseless Age* of October 2, 1907, set forth a formula, as follows:

$$H.P. = \frac{P\,f\,r\,R}{63{,}000\ \sin\Phi};\ \text{in which}$$

P = the assumed pressure of the spring;
f = the coefficient of friction;
r = mean radius of the cone, in inches;
R = angular velocity, in revolutions per minute;
$\sin\Phi$ = sine of the angle of the clutch.

The formula transposed is as follows:

$$P = \frac{H.P. \times 63{,}000\ \sin\Phi}{f\ r\ R}$$

In this way the spring pressure may be approximated. It is important, however, to use a coefficient of friction such as wil' serve under practical conditions (Mr. Chabinger adapted the coefficient 0.25) which, in the author's judgment, will not hold in practice for any length of time, if leather is the facing used. If cork inserts are adopted, the coefficient would be a safe one to use, and it might be even higher. The coefficients for cork are given. If the facing is of leather alone, it would be wise to adopt the coefficient 0.15, as before given for an oily condition.

If 40 pounds are all that one would care to hold on the pedal, then it is plain that the value of P should be limited on that account. The ratio would then be 5:1, which ratio can be taken care of in a lever system. On this basis the dimensions of a 50 horsepower clutch, 1,000 r.p.m. would be about as follows:

$$P = \frac{50 \times 63{,}000 \times 0.15}{0.15 \times 9 \times 1{,}000} = 350 = \text{pounds pressure of the spring.}$$

This is for an angle of about 9 degrees and, as will be observed, the spring pressure is somewhat higher than was the wont. This merely indicates the near approach of the limit of the cone type of clutch. The value taken for r is high enough to engender spinning, which is not to be desired, and the value of R is quite as high as it ought to be in a 50 horsepower motor.

Even so, it is a matter to be ascertained, if the ability of the clutch in terms of negative torque, will be adequate for a lasting clutch of the requisite maximum holding power. The constant 63,000 would have to be adjusted to suit the conditions, were it proven that the ability of the clutch in terms of negative torque falls below the desired value, which was set at double the positive torque, *i.e.*, the mean effective torque of the motor.

The question of the spring is one to be looked after with some care, and of it there is oftentimes some reason for believing the right proportions are not arrived at. The table of helical springs here given is one that will help out vastly if it is consulted. For this class of service the maximum carrying capacity in pounds can be taken. The table explains itself adequately. The range of the table is so great that it will handle all the problems of the clutch spring and if more or less than ten turns are desired, it will be possible to figure out the resultant ability with more or less than the ten turns taken in the table. The table was compiled by Max Hesse, while assistant to the author in connection with the Simplex Cars.

Neglecting the question of slipping from the utility point of view, we can take up the matter of the multiple disc type of clutch, with the idea of showing how it can be made to hold with greater certainty than would be the case were the discs plain. The Hele-Shaw clutch, for instance, as will be shown in Fig. 6, is of the multiple disc type, but the discs instead of being plain are provided with wedge-shaped indentations at a radius somewhat greater than the inside diameter of a disc.

A- MAXIMUM CARRYING CAPACITY IN LBS.

B- DEFLECTION AT THIS LOAD FOR A SPRING WITH 10 COILS.

C- COEFFICIENT OF STIFFNESS, WHICH CAN BE USED FOR CALCULATING THE DEFLECTION OF A SPRING WITH N COILS: $\delta = \frac{P.N.}{32\cdot C}$

The utility of the wedge-shaped indentations would be the same as that of the cone bearing surfaces of the cone clutch.

e Hele-Shaw clutch it is not necessary that the discs should upon their faces, since the clutching effort may be con- to the engagement of the wedge-shaped depressions. A ı of this sort bas but a small bearing surface per disc, making each disc very effective, and as to the effect of ıigh pressure on the small surface, it is compensated for e use of a considerable number of discs. Tbe discs them- ; are very thin, and it is possible to use a considerable er of them within limited space. The other features of lutch will scarcely require attention, since they are plainly ı in the illustration, and tbe idea here is to point out the ence between this and simple multiple disc clutches.

Concerning Spiral Band Clutches.

Mercedes type of spiral band clutch is probably the best ı of any in this class. It consists essentially of a flat l spring wrapped around a hardened steel drum. One f the spring is anchored to the driving member and the end is actuated by means of a spring pressure through a arm. Intervening the spring and the lever arm is a slid- ɔne with a face-angle of about 52 degrees, ending in a and a slight reduction in the diameter beyond. The pressure is thus multiplied, first through the good office lever arm; second, by the wedging action of the sliding and, finally, by the wraps of the helical band around the There are usually from four and one-half to five wraps band on a drum approximating 6 1-2 inches in diameter, ıg slightly in this respect in the different types of cars. um is of hardened alloy steel, the texture of which metal ery close as to permit of extremely bigh pressures with- y eroding effect at all. If the drum is hard, it is true ıe helical bands must not only be hard as well, but of rength, since the pull on the wrap nearest to the anchor- ıches a very high figure indeed.

e is a certain amount of complex mechanism in con- with clutches as above described, and the clutch, Fig. 7, t belongs to the same genera of clutches, is designed e idea of eliminating the complex features. In this spiral utch the helical band is wrapped around a drum of the pe; one end of the flat band is anchored to the driving , while the other end is free. To engage the clutch the tself is caused to telescope the helical spring and by a ce in angle between the drum and an outside housing end of the spring is pinched in such a way as to con- ıe same, thus affording the requisite negative torque to t the torque of the motor.

is type of clutch freedom from lever arm troubles is a lent feature, but if the lever arm is eliminated, high has been substituted instead, and this high pressure ɔn a small area at the end of the helical band, which n time erode the band itself or cause it to burrow into ace of the drum in juxta-position. These evil influences be counteracted if the materials used are of a character l the greatest possible hardness witbout brittleness. In wo cases it was suggested that a hardened tool steel in- ɔe used at the point of maximum pressure. This might od idea, but the author does not know of any case in is has been taken advantage of.

the industry has developed a considerable number of now obsolete, yet even so there are one or two ideals sist in coming to the fore at ratber frequent intervals. ɔr instance, the question of an individual clutch for the speeds in the gear-set. This scheme has been used ensively, and has many advantages, among which might oned the fact that the gears are retained in constant scheme of this sort resolves itself into the question of or not a separate clutch for each gear is preferable to clutch for all of the gears and a sliding mechanism by f which the gears may be engaged. There are very ırently whose preference seems to run in the path of clutches to get away from clashing gears.

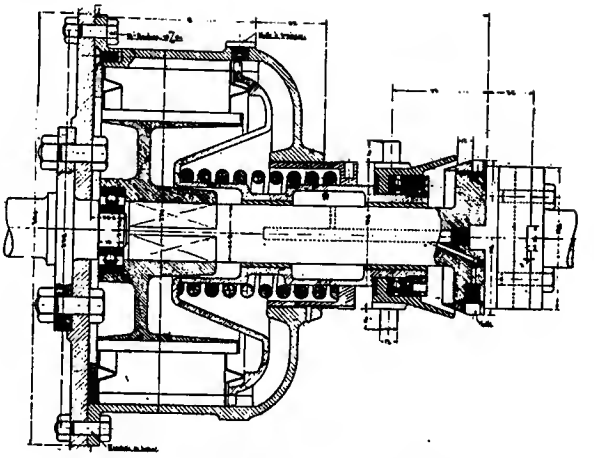

Fig. 6.—Sectional view of the new Hele-Shaw clutch.

There is still one more idea that seems to be buoyant, although it has not been exploited to any great extent up to the present time. This idea has for its basis the use of a unit clutch in the ordinary way, and the gears in the gear-set in constant mesh. In order, however, that the speeds may be changed, sliding cones provided with slots, teeth or other means of engagement afford the methods by which the respective gears in proper selection are locked in place and set to perform their functions.

Obviously this is a means for side-stepping the clashing of gear teeth, hoping thereby to save them from the results of clashing, but it must be plain to even a casual observer tbat the trouble is merely transferred to another point. It seems to be true that there is less wear and tear due to the clash meshing of gear teeth than follows the use of other means of locking members, such as pins, a screw-driver joint, etc.

The Question of Lever Advantage.

It was said that if the engaged faces of the clutching members were direct the pressure of the clutch spring would have to be sufficient, in view of the coefficient friction of the materials used for the clutching purpose. It was pointed out in the case of the Mercedes clutch that an intervening lever arm might be devised in some way as to multiply the pressure of the spring, and it was there intimated that a cone-face might be so shaped as to afford a further lever advantage, due to the wedging action. The use of the spring tabulation previously given will be much facilitated if information is at hand bearing on the question of the lever advantage.

It is easy enough to see to what extent a lever arm will decrease the needs by way of a spring. It will be remembered also that a means was afforded for determining as to the magnitude of the advantage if the simple wedge is used in connection witb a lever arm. Nothing remains, therefore, but to exploit

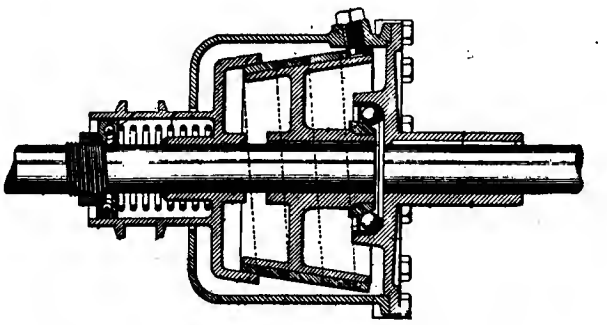

Fig. 7.—Cross section of the Ellsworth-Fay clutch.

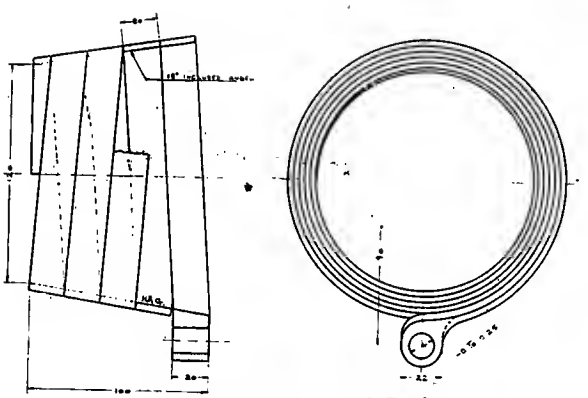


The Ellsworth-Fay Clutch Band.

the means by which the advantages of the cone-type of clutch may be fixed.

The first question is one involving the disengagement of the clutch. To engage is a necessity, and to prevent slipping is desirable, but, as before stated, we must know that the disengagement will be sure. With metal to metal contact, considering such metals as are likely to find their way into clutches, the disengagement would not meet with any unusual conditions. If, on the other hand, leather (or such other materials as would act in the same way) be used, it can be the cause of sticking, and the disengagement might be attended with unusual difficulties, *or becomes quite impossible.*

If a cone clutch is allowed to slip for a time it will get hot. If it is then allowed to stay engaged for a considerable period it will disengage with difficulty. The prime reason for this lies in the fact that during the period of slipping the female member (of metal) will be heated more than the male and will expand more. The members will then nest closer and when the clutch members cool off the engagement will be under far greater pressure than that due to the normal pressure of the spring.

Leather faced cone clutches, then, are not suitable for the class of work in which slipping is intentional, with a view to controlling the speed of the car, even for a short time. The expansion of the male member due to heat will be as follows:

$$e = (1 + f \times {}^{\circ}F)\ D.$$

In which

e = total expansion due to heat.
f = the coefficient of expansion of the materials.
°F = increase in temperature in degrees F.
D = mean diameter of the member, in inches.

It will be well to take into account the fact that the male member is insulated as against heat, the leather acting as an insulator, so that little or no expansion will be noticed in that member.

Since slipping cannot be prevented with certainty, an allowance should be made in the designing of the pedal system, such as would assure to the operator unquestioned ability to apply enough pressure to enable him to disengage the clutch. Since there is a limit to the ability of the operator to apply pressure, there should be such a lever advantage provided as would assure the disengagement of the clutch with a predetermined effort well within the ability of a person of no great strength.

If it can be assumed that a person of no great strength can press on a pedal on a basis of 100 pounds, then it is safe to say the clutch should be designed to respond to that pressure under the most severe conditions. Under ordinary conditions, however, the pressure should not exceed, say 40 pounds. This latter pressure would take into account the resistance of the spring only, on the assumption that normally sticking would not ensue in reasonably designed clutches, in correct alignment.

In a cone clutch the resultant of the pressure of the spring will be greater than that pressure. The coefficient of friction, however, undergoes the equivalent of a change, in that the coefficient becomes much diminished during the time the members are engaging, because of the manner of the engagement. This is explained on the basis of the effect of screwing one member into the other, as it were, which is what happens, since during the act of engaging the driving member if at a higher angular velocity while the driven (male) member is being pressed deeper into the engaging position. The result is, a point on the periphery of the male member will describe a spiral orbit during that period.

Members that cannot be telescoped at all by fair axlewise motion may readily telescope if the spiral motion is imparted to the one of them. It matters not at all if there is an actual diminution in the coefficient of friction, since the resultant of the process is the equivalent of a diminished coefficient.

Pressure on cone faces:

$$N = \frac{P}{\sin \alpha + \text{tang } \phi \cos. \alpha} = \text{total normal pressure between cone faces.}$$

$$P = N \sin \alpha$$

The motor ability must be less (somewhat than the value of N). This ability would be found as follows:

$$P^1 = \frac{2 \pi r S}{\text{H.P.} \times 33{,}000}$$

in which

r = mean radius of the cone clutch.
s = angular velocity r.p.m.
H.P. = actual delivered horsepower of the motor at the speed s.
P^1 = pull, in pounds, at the periphery of the cone clutch.
P = $P^1 \times 2$ for clutches that should sustain under severe conditions.

SOMETHING ABOUT SPRINGS.

If a short leaf breaks, even though it may be an intermediate member of a spring, it is a good sign that the camber of the broken leaf was greater than that of the other leaves. Since the fiber strain would be the same in all the leaves were they all of the same thickness, and curved to the same radius, it is fair to reason that any one leaf curved to a shorter radius will be subjected to an excess fiber strain and will rupture the sooner in consequence.

It is very likely that a spring on the whole will work better after the short leaf, with its excess camber, is eliminated. At all events, such an occurrence on the road should not be a source of great annoyance to the motorist, since the remaining unbroken leaves will be in no greater danger of breaking than they were before. Indeed, the unbroken leaves may be in prime condition, since it is possible that the broken leaf of the excess camber sustained more than its share of the work up to the time of rupture.

Sometimes these seemingly unaccountable breakages of intervening plates (leaves) in the springs are due partially to excess camber and for the remaining part to loose clamping. No spring of the laminated type will sustain in service, if it is not tightly clamped. It is not enough to tightly clamp the springs to the spring seats on the axle. The material should be superior to that of ordinary vehicle bolts and of greater section, because much is to be gained by affording seat of the radius in conformity with the radii of the spring plates. A leather facing skived to the curvature of the main leaf of the spring is of great value, primarily because it lends friction to the clamped members, and again because it yields to the high spots, and more closely nests the clamped spring to the seat. A properly clamped spring to the spring seat with an intervening leather pad will scarcely give trouble at all.

It is a waste of time to use spring clamps of indifferent material and small section, in work of this character, because the clamp itself will yield, and allow the spring to go adrift. The clamps must be of good material and of adequate section to maintain a tight relation, in order that tight clamping may be a continued condition.

LETTERS INTERESTING AND INSTRUCTIVE

PERTINENT POINTERS FOR THE SALES END.

litor THE AUTOMOBILE:

[1,597.]—I would like to ask through your "Letters Interesting id Instructive" if there are any automobile manufacturers who fer premiums to users of their machines, making ths bsst sug-stions as to points of improvement on their respective cars. Ars ers any automobils manufacturers who make it a point to kesp iplicats parts of their machines in all large cities, so that hroken irts can be quickly repiacsd? Is it asking too much of a dsaler hen he triss to sell you a car if he expects to carry duplicate parts stock?

Would not an effort on ths part of automobile manufacturers to elp mors thoss to whom they have sold machines in the past, an to make such heavy cuts to facilitato the sale of new onss? ake, for instance, ths cash register people and the Remington pewritsr people; once a customer they count you as a friend and istomer always, and ars continually eending you such information will help you in getting all possihis out of ths purchasss that ou may havs made. R. T. H.

Port Norfolk, Va.

So far as our knowledge extends, there are no American akers who are offering any premiums for information of this ind, though prizes have been held out for records of the low-st maintenance expense on the greatest mileage, and at least ne of these is still effective. There are few of the larger merican automobile manufacturers who do not carry very com-lete stocks of replacement parts in their branches in different ities, and several have made it a point not only to sell these arts at prices corresponding to their first cost on the machine self, but also to supply them very promptly.

The question regarding parts would be a most natural and gical one, and is usually asked under such circumstances. We gree with you most heartily regarding the value of the policy f "once a customer, always a customer," and are under the npression that this is closely followed by the majority of well-nown makers.

HOW TO LEARN THE AUTOMOBILE BUSINESS.

litor THE AUTOMOBILE:

[1,598.]—I am employsd in an automohile repair shop where I n supposed to bs learning the automohile business, but am not ven a good opportunity of doing so, owing to being givsn other rk to do. I would like to have you inform me whether thsre is t soms way of learning this without interfering with my work d without going to an automohile school. Would it henefit me y in my work to take up the study of gas engines?

Chicago, Ill. OTTO L. HARTMANN.

You do not state what branch of the business you wish to rn, whether designer, salesman, repair man or chauffeur, or at is the nature of the work to which you are assigned; but this work is in any way connected with the repair shop, it ght to be of use to you. If not, why not try some other repair p? That is certainly the best place to learn. We do not ieve that it is possible to learn the automobile business, or other business, without devoting one's whole time to it. The dy of gas engines would certainly be of benefit to you, but would be better to get a practical knowledge of them first.

ANOTHER WHO UTILIZES HIS OLD CASINGS.

tor THE AUTOMOBILE:

,599.]—I find it unnecessary to rivet or tis on with rawhide old s with beads cut off. Simply put on with the new tire elack and up. I have soms that have been run a thousand miles over h mountainous roads and they have not crawled one-sixtieth n inch hy a mark I made. This is much less work to remove, se of a puncture. OWEN B. AMES.

rfield, Ms.

here is certainly no advantage in troubling to rivet or lace he old casings when it is desired to use them to protect ones if they stay in place when simply put on slack and blown up. This simplification of the process should en-age other automobilists to try it—many of whom, no doubt, ated at the work involved in the other methods.

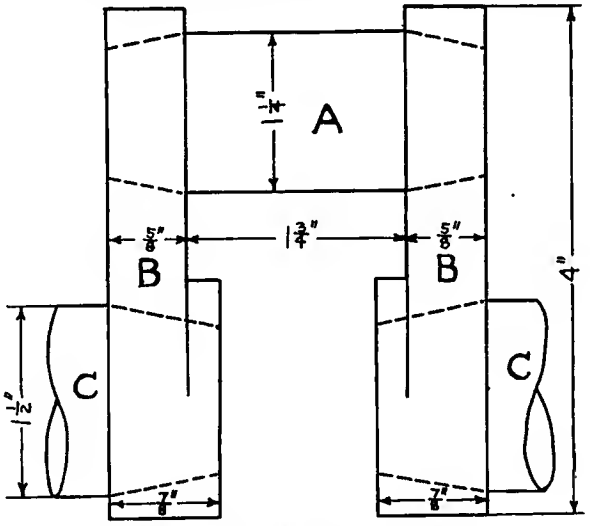
PARTICULARS OF A BUILT-UP CRANKSHAFT.

Editor THE AUTOMOBILE:

[1,600.]—Enclosed is a rough sketch of a huilt-up crankshaft with dimsnsions. My idea is to have the discs B mads of cast iron or phosphor hronze and to have ths crankpin C and wristpin A tapered and keyed to the discs. The dimsnsions given are the only ones possibis for me to use. The pins I plan to have mads of tool stssi, hardened, ground, and highly polished. Do you think a crank of this kind would give satisfaction? Thank you for any help you may give me. BUILDER.

New York City.

It is difficult to tell what satisfaction your crankshaft will give without knowing the size and other data of the cylinder. Moreover, your object in making the pin smaller than the main journal is not apparent. You say these dimensions are the only ones possible for you to use, but it would seem that the requirements of such an important part of the motor as the crankshaft should not be subordinated to any others. There is no particu-



Proposed Design for a Built-up Crankshaft.

lar advantage to be gained by making the crank cheeks discs instead of rectangular, as shown in the drawing; the extra material would only be wasted. The drawing does not show nuts to hold the discs on the tapered ends of the pins, but these, of course, should not be omitted. We think it would be the best economy, however, for you to have your crank forged in one piece by some concern with the proper facilities.

PUZZLING KNOCK WHEN CLIMBING ON THE HIGH.

Editor THE AUTOMOBILE:

[1,601.]—In your "Letters Interesting and Instructive" pleaee give me some advics on the following: I have a 35-horsepower, four-cylinder, shaft drive, '08 car. There is a certain kick in this car when pulling up a heavy grade on the high gear with ths throttis wids open. This kick or hack-lash feels as if the whole machinery was locked. The car vibrates the sams as a car does when, in coasting down hill with the motor dead, the clutch is suddenly dropped in to pick up the motor; that is, a sudden jarring or jerk hackwards, iiks the geare locking in ths differential. Ths car has always done this.

I thought at first that it was in the rear axie, it being the sams sometimes as if the bevel gears should fail to mesh and ths testh should lock on top of each other. On examination of ths axle, I found ths hevel slightiy cut. I put in a new axle, which I have run for 1,500 miles, which is not worn, but still have the same trouble. Sometimes on releasing ths clutch when this kick occurs ths car will coast for a few feet, but on dropping in the clutch again to pick up ths motor it will vibrats as hefore.

When the muffler is cut out it seems as if this kick cómes on a

weak explosion; at other times the explosion seems about half trong. This, of course, occurs when the car is pulling about 80 cent. of its capacity on an up grade, the throttle wide open, yet oes not feel like a miss. The position of the spark lever makes ifference. Sometimes the car will kick several times and still up and go ahead, at other times it will kick and stop. The ng is exactly as if the machinery was suddenly locked. I have experts, some from other cities, trying to locate this trouble, all have failed. I will value the car $200 higher the minute I te this trouble. Can you give me any idea of where to look her? SUBSCRIBER.

uluth, Minn.

rom your description it seems as if the trouble ought to be in running gear or transmission rather than in the motor. How- r, replacing the entire rear axle should certainly have stopped kick if the cause was in that member, so we should suggest mining the change-gear. It is possible that the reverse pinion / be loose and slip partially into mesh when the car is in- ed on a grade, or the shifting mechanism may allow the ing member for the low gear to engage, if the change-gear is the selective type. In the latter case, however, this looseness ild have made itself apparent in other ways. Another possi- ty is looseness in the universal joints. If the "kick" seems to ie when the car strikes a bump in the road it may be that the ling joint in the rear universal (if the drive shaft has two) erferes with the action of the universal itself. We confess t it is a puzzling case, and we would be glad to hear from any our readers who have had similar difficulties.

WILL TWO PORTS RESULT IN MORE POWER?

ttor THE AUTOMOBILE:

1,602.]—I have been a reader of your publication for about two ars and have every copy where I can locate it at any time. My nner of preserving the copies is to lay two months' issues (about ht or nine volumes) together evenly, then clamp them there th two 18-inch boards and two 3 3-4 by 1-4-inch bolts, then bore ir 1-4-inch holes through the whole pack about three-quarters an inch from the backs, and then lace them with common shoe ings. This keeps the copies where they can be referred to at y time and is little bother, whilst the cost is next to nothing. I would like to inquire if the power of a three-port two-cycle otor would be likely to be increased by converting it to a two- rt motor? SUBSCRIBER.

Moline, Mich.

While your method of preserving back numbers of THE AUTO- OBILE is certainly one that makes for solidity and durability, we ould think the same laudable objects might be obtained, as has en the case in automobile construction during the past five ars, with a little less avoirdupois. As you say, the cost of our method is not very great, but for actual service, a good ady-made binder obtainable for very little from any stationer, ould compare as good steel does to a cheap casting.

Specifically, we cannot say what will happen if the particular otor to which you allude were to be changed over from a ree to a two port proposition. Taking an abstract case, the spective motors properly designed and suitably constructed ould compete with each other under favorable circumstances s respects ability to deliver power.

GRAPHITE AS A CYLINDER LUBRICANT.

ditor THE AUTOMOBILE:

1,603.]—Kindly tell me if graphite is a perfect cylinder lubricant ithout being mixed with oil, in an engine in which the short- circuiting of the ignition current is of no importance. How high a emperature will graphite stand without losing any of its lubri- ating qualities? Does it leave a carbon deposit similar to that of il? Can it be fed through a gravity-feed oiler? READER.

St. Louis, Mo.

Graphite is one of the best lubricants known for any purpose. The only objection to its use in automobile cylinders is that it is ikely to clog up the oil pumps and leads. Its lubricating qualities are independent of the oil, and if you can devise a reliable method of feeding it without mixing it with oil you will certainly get atisfaction. It will stand any temperature usually found in a gasoline engine cylinder; the temperature at which it decomposes will naturally depend on the grade, and the manufacturers will be able to advise you better concerning this. A gravity-feed oiler would not be suitable; force-feed is necessary. But why worry about graphite if you have invented an engine in which the short-circuiting of the ignition is of no importance?

IS THE MAGNETO LESS TROUBLESOME?

Editor THE AUTOMOBILE:

[1,604.]—Will you please inform me through "Letters Interesting and Instructive" if you think a magneto for a 30-horsepower four-cylinder car is worth the extra expense? Also, what will a good one for the jump spark system cost? Will it be any more trouble to keep in working order than the battery system, with batteries, coils and commutator? PROSPECTIVE OWNER.

Asheville, N. C.

The magneto will certainly afford you adequate compensation by way of reduced ignition troubles and increased power, in spite of the fact that you can pay as much as $200 for a magneto, inclusive of its fittings, ready for installation. Magnetos for the jump spark system can be had at prices ranging between $100 and the high limit as above set down. The magneto will be less troublesome to maintain, requiring but little occasional care, by way of cleaning and oiling; during its natural life, which for a good magneto, is equal to the life of the motor.

OIL FOR COOLING IN COLD WEATHER.

Editor THE AUTOMOBILE:

[1,605.]—I would like to inquire through your "Letters Interesting and Instructive" whether a very thin oil could not be used for cooling in the winter in place of an anti-freezing solution. Also if the results would be as good, and if the cost would be any more, and how often the oil would have to be changed to get the best results.

Boylston Center, Mass. A. R. BENNETT.

Oil has often been used for this purpose, and we believe that one of the large manufacturers advertises a special brand for use in cooling systems. The results will be all right, but you will probably find the oil more expensive than the ordinary calcium chloride solution. There would be no necessity of changing the oil during a single season, but more would have to be added from time to time to make up for evaporation. Perhaps some of our readers who have used oil can give you the benefit of their experience.

MAXIMUM SPEED OF AUTO AND CYCLE MOTORS.

Editor THE AUTOMOBILE:

[1,606.]—What is the highest speed attainable in four and six-cylinder four-cycle automobile engines, and in four-cylinder motor-cycle engines? G. L.

St. Paul, Minn.

The speed depends on the load, the size of the motor, and many details of its design. For the average automobile motor, either four or six-cylinder, the maximum speed under load may be taken at about 1,500 r.p.m. If the motor were allowed to "race," running idle, it might turn as high as 2,500 r.p.m. For motorcycles, the figures might be about 2,000 and 3,000 r.p.m., respectively. In motors for every-day service, the piston speed, under load, rarely exceeds 1,200 feet per minute, and this, of course, determines the number of revolutions.

REGARDING THE FORM OF LUBRICATION.

Editor THE AUTOMOBILE:

[1,607.]—The recent stringent measures taken by the police in New York City against the drivers of machines emitting smoke from their exhaust and the probability of equally stringent action on the part of local governments in other districts, render it necessary for manufacturers either to subtract from the efficiency of their cars or to revise the systems of lubrication which they have adopted. Since in the great majority of cases the only sign of sufficient lubrication for the engine has been the emission of a slight blue smoke from the exhaust, makers, in many cases, advise customers to make sure that their exhaust is smoking continuously.

Realizing the hardships that such regulations impose upon makers of such cars, it is not out of place to consider the various general efficiencies of lubricating systems in vogue. The most usually employed is the splash system, in which the connecting rod-ends whip the surface of oil in the crank base, so throwing

to the cylinder walls and other moving parts. In the crudest rm—the most common, by the way, of this system—the oil is d direct to the crank basee and only about 5 per cent. of it is fective for lubrication. If the oil level is too high, the engine ll foul and the exhauet smoke; if too low, the engine gets no , with disastrous results.

The anti-smoke properties dspend entirely upon the accident of s driver accurately gauging the feed to the crankcase to supply as used, a condition which varies, however, with the imme- ite mechanical quality of the car and also with different oils.

n an improved form tbe oil, in considerable quantity, is car- d in a lower chamber or sump, whence it is automatically mped to the crank basee, being kept therein at a constant level means of a simple overflow device. This system is infinitely ter than that previously mentioned, since about 60 per cent. the oil carried may be used before trouble will occur. But the stion of a smoky exhaust depends upon a very accurate gaug- of the capacity of the overflow from each and every one of crank bases. Moreover, there is in this as in every splash tem, the serious disadvantage that the copiousness of the lubri- ion bears but little relation to the work imposed on the engine.

ttached force feed lubricators entail a complication of tubes ly to clog or leak and again depend upon an accurate setting, ch necessarily varies with different engine epeeds and for which appy average only can be struck, a state of affairs not in ordance with the high efficiency necessary with the modern omobile built for a critical purchaser.

y far the best system in every way is that in which a force p draws oil from a sump, forcing it by means of suitable s in the main bearings through passages in the crankshaft to crank pins, thence to the piston pine, whence it escapes back he oil reservoir, the cylinders being lubricated by the oil wn by centrifugal force from the crank webs. Since the force p ie driven from the engine, the pressure in the oil system rectly proportional to the speed of tbe engine—the flow equally as is also the amount thrown from the crank webs to the ders. It is this system—to some makers a new idea—which leveloped on the Marmon car eome six years ago and which ave always used. It is this system also that has rendered ble—as records show—the extraordinary speeds for extended ds which have been made upon the Brooklands track in Eng-

With it not only is perfect lubrication of every engine part utely insured, bnt the whole quantity of oil in the system may ed up befors lubrication fails.

vided the by-pass is correctly set, it is impossible to make ngine smoke; the whole system is integral with the engine ut exposed pipes to leak, or indeed any to clog. Once tested he by-pass set, the driver may forget once and for all, ex- or a very occasional replenishing, his lubrication system, and e happy in immunity from an annoying arrest for an offence is primarily due to the maker neglecting to use the best ble system for that most important of all the functions in eration of automobile mechanism—lubrication.

rite this, since, with many low-priced and attractive cars the public for the coming season, it is necessary for a to examine such matters closely, both to comply with a o-be universal regulation and for the sake of his machine's l efficiency and freedom from repair.

napolis, Ind. HERBERT H. RICE.

I ENTHUSIAST ON UNREASONABLE LAWS.

THE AUTOMOBILE:

3.]—The canal came first, then the steamboat, then the railroad; the horse-drawn street car was superseded by ole car, and it in turn by the electric street car. The jin- or man-drawn cart, was supereeded by the ox-team, and it horse—and it in turn by the automobile. And so it comes to iat we to-day are enabled to cover great distances quickly e fast becoming one great community. As a natural se- to the fulfillment of the inexorable law of progrees has come the advent of the automobile. The same spirit of antedi- ideas that opposed the progress of rapid transit heretofore are bitterly opposing the automobile. It is the tendency to go to extremes, first too far one way, and then too far ier way, until finally a middle course acceptable to the iajority is reached.

present road laws are the extremes of restriction, unjust criminating detrimentally to the automobile. Towns, vil- nd cities that pass speed limits of 8 to 10 miles an hour ot the mark of reason and senee. If laws were passed the speed of automobiles to 10 miles in congested sections s and cities and 15 miles in the free sections, with 20, 2b iles in the conntry, they would be reasonable, would be dhered to, acceptable to all sane automobilists, and work ;ker than any other measure the desired end of safety. is an hour, except in the most congested business sections, tly ridiculous. Fifteen miles an hour is the happy medium and safe. An automobilist who will drive even out in the open country over 30 miles an hour ehould not be fined, but sent to jail, because he has gone to the other great extreme.

Now, what we are advocating is a reasonable, fair, and happy medium of speed limitations. It is what will come ultimately, and the quicker adopted the quicker all drivers of automobiles will fall in with hearty accord and aid in its maintenance.

Oil City, Pa. ONE AUTOIST.

"INDUCEMENTS" TO AUTO SALES AGENTS.

Editor THE AUTOMOBILE:

[1,609.]—A sales company controlling the sales of a popular car in the State of Minnesota offer the following "inducements" to dealers: The dealer must deposit part of the payment of five cars without any security whatever with the sales company, must not sell any other car without permission from the sales company, and must keep in stock four different styles of the car for demonstra- tion. The dealer must sell at the price which the manufacturer may eet, no matter whetber below what he hae paid for the car or not, and if he fails in any particular to live up to the contract his deposit is forfeited to the sales company. This business proposition seems to me to be the worst jug-handled, sucker-catching scbeme that ever went under the name of iegitimate business. The sales company ask the dealers to furnish them capital to do business with, with absolutely no security or recompense, arranged so that the deposit may be declared forfsited at their own sweet will, and do not even agree to furnish the cars which the deposit is part payment upon. They limit the business of selling to their permis- sion and compel the dsaler to keep in stock models which may not be salable in his locality.

In my opinion, this method of selling automobiles to dealers will spell suicide for the manufacturer if it is rigidly enforced. It will stimulate the most zealous antagonism to the car and will enlist good agents in the ranks of salesmen for other cars.

Marshall, Minn. A. D. HARD, M.D.

A GASOLINE SPRAY FOR CLEANING MOTORS.

Editor THE AUTOMOBILE:

[1,610.]—I note letter No. 1,587, by F. C. Snedeker, in regard to cleaning the engine of an automobile witb gasoline spray from a tank in which the air has been compressed. Will say for his infor- mation, that in 1906 I received a circular from a concern in Utica, N. Y., in which one of their speciai offers was the "New Lightning Automobile Cleaner," consisting of a four-gallon galvanized iron tank with air pump attached. They state that one gallon of gas- oline and one pint of kerosene put in the tank, and the air of same compressed, would instantly remove grease baked on the engine.

This appealed very strongly at the time to me, but never having heard of it before or seeing it advertised after, I thought perhaps it was not much of a success, and so failed to carry out my intentions of ordering one. The price was $6.

I agres with Mr. Snedeker that I believe something on this order would be a very useful article for owners of automobiles, and would find a ready sale. I am writing tbe Utica concern to-day to see whether they still manufacture tbis cleaner.

Middletown, Conn. G. ELLSWORTH MEECH.

DR. KRESS GETS MANY DECARBONIZER INQUIRIES

Editor THE AUTOMOBILE:

[1,611.]—Since my letter in the October 1 issue, headed "Concern- ing the Use of Decarbonizer," I have received many letters asking for more complete information. Since I do not have the time to answer all these numeroue letters. I would ask that you make known that it is the Radium decarbonizer which I use, and the oil is of the Monogram brand, and the car which I drive is a Franklin. The other night I was called out of my bed to answer a long- distance telephone from Philadelphia in regard to more complete information.

I have no personal interest in the decarbonizer, the oil or the car, and simply wroto the original letter for the benefit of my fellow automobilists and thought they could get some good results from my own experiences. PALMER J. KRESS, M.D.

Allentown, Pa.

ANOTHER CURE FOR POPPING CARBURETER.

Editor THE AUTOMOBILE:

[1,612.]—In answer to No. 1,578, this will probably cure the trouble: Put in a few set of dry cells; see that vibrator points are clean; adjust vibrator to give a good hot spark. Then turn needle valve on carbureter entirely down, and open it three-quarters of a turn. Now start engine, and move needle valve up or down a very little until motor runs smoothly, and go on your way rejoicing. Be sure to connect up dry cells as the instruction book says, six cells in multiple series. I have a Mitchell, too.

Corsicana, Tex. CLARENCE THOMAS.

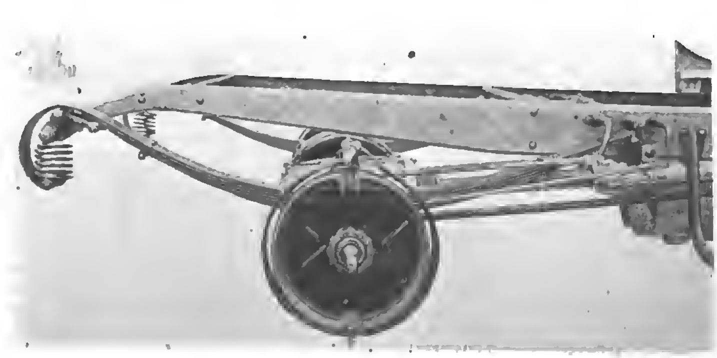
The Ramblers for 1909

THE Rambler design for 1909 exemplifies the usual policy of continuing former models, with only such refinements in etail as experience has shown to be desirable. The two-cylinder 2-horsepower and the four-cylinder 34-horsepower cars follow ery closely the coresponding designs for 1908. There is, howver, an entirely new four-cylinder model of 45 horsepower, elling as a roadster or touring car at $2,500. Various styles of unabout, touring or limousine bodies may be fitted to this hassis. The two four-cylinder models are exactly alike in esign, differing only in motor size and power, wheel base, tire ize and body capacity.

Refinements in Motor Design.—The 34-horsepower motor as cylinders 4 1-2 inches "square." As used in 1908, it delivered 2 horsepower, but increasing the size of the valves and the arbureter capacity justified a higher rating. As in preceding models, the most distinctive feature of the motor is the offset rankshaft. This proved in practice an even greater advantage han was expected. The flexibility and power at low motor peeds are further augmented by an increase of twenty-six pounds n the weight of the flywheel rim. The makers claim that it is ow possible to throttle a four-cylinder Rambler as low as three miles an hour on the high gear. The two-to-one gears have been oubled in width, and the driven gear is now of rawhide; with hese improvements and careful machining, the gears are absoutely silent. The crankcase is in one piece, the crankshaft with ts assembled bearings being inserted through the rear end. Both he main and the connecting rod bearings are of the marine wedge ype, and may be easily adjusted through a hand-hole 8 x 23 nches on the rigbt side of the crankcase. It is hus no longer necesary to remove the mud apron and the oil pan, and, to still further facilitate adjustment, the front mud guards have been made of the quick-detachable type. The exhaust manifold has been raised to allow easier access to the valve stems and springs and the adjusting nuts. The relief cocks in the cylinders are of a new type. They are, in fact, check valves, which are held closed by springs and by the pressure in the cylinders. The higher tbe pressure the tighter they become, preventing leaks through wear.

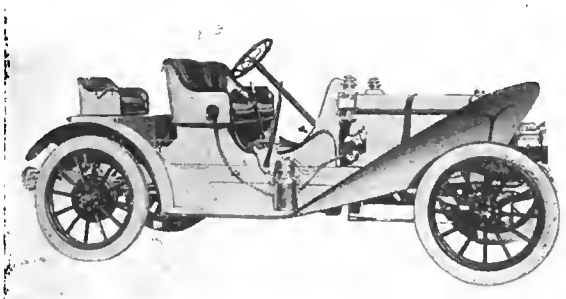
Passing to the ignition system, it will be noticed that the timer has been placed in a higher and more accessible position, and flexible cable is now used to carry the primary as well as the secondary current. The spark plug terminals are of a new and convenient design. The wire ends in a fiber block, which is attached by a bracket to the upper water pipe. A thumb screw locks the bracket in any desired position. From the block a metal strip extends to make contact with the flat metal bead of the spark plug. Should missing occur because of soot on the spark plug points, raising the fiber block slightly will form a spark gap between the strip and the plug head, and the missing will be temporarily overcome without changing the plug. When it is desired to remove the plug the fiber block may be raised clear, and the cable need not be disconnected.

The pump is now driven from a straight shaft on the side opposite the camshaft. It is entirely detached from tbe crankcase, so that if a leak should arise water cannot enter the two-to-one gear housing or the crankcase. The end of the pump shaft is arranged so that a magneto may be coupled on if desired. The standard Bosch high-tension magneto will be carried in stock and furnished when ordered at an extra cost of $150, forming a complete double ignition system. This specification will cause no delay in the filling of orders. The magneto is located at sufficient distance from the crankcase and the oiler to allow easy access for inspection and adjustment, and may also be readily removed.

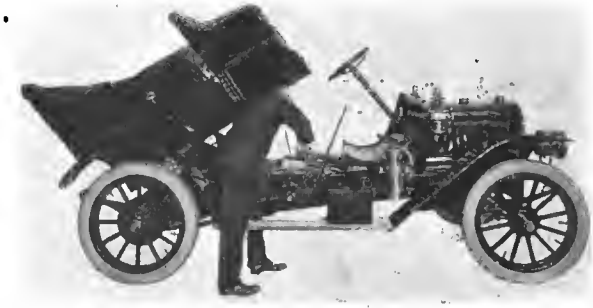


Mounting of the Rambler New Triple Action Springs.

Lubrication is cared for by a mechanical force-feed oiler, of a capacity 50 per cent. greater than that used in 1908. The oiler is also located rather farther back, to permit better access to the magneto. It is placed in an oil tray arranged to catch any overflow, and flying oil from the flywbeel and clutch is prevented from spreading by a metal guard.



Rambler Type 44 A-1, Four-cylinder Roadster.



Motor Accessibility on the Two-cylinder Rambler.

Concerning the Transmission.—The inverted cone clutch formerly used has been replaced by the direct thrust type. The cone is made of pressed steel instead of aluminum, thus being less liable to distortion from severe use, and the surface bas been increased about 50 per cent. It differs from other clutches principally in tbis greater surface and in the arrangement to vary the tension of tbe spring. Tbe adjustment is so easy and so accessible that it can be attended to on the road at any time, thus eliminating any excuse for burning clutch leathers. Studs extending from the inner surface of the cone contain spiral springs placed under the leather to insure gradual engagement. To stop the spinning when the clutch is released, a camel's hair block is placed in the bearing of the releasing arm to give a braking action.

Tbe change-gear remains the same as before, but a slight change has been made in the shifting mechanism. The reversc gear is engaged by bringing the lever directly back of the position for the first speed forward. To prevent an inexperienced operator from going into reverse in attempting to change from first speed to second, a bell crank is so placed on the quadrant as to interfere with the backward movement of the lever into the reverse slot. When it is desired to engage the reverse the crank may be displaced by pressing a button conveniently set in the floor.

A feature which will be appreciated by owners is the provision for brake adjustment. Both the foot and the lever brakes may be tightened by shortening the rods which connect the pedal and lever to the equalizing shafts. At the front end of these rods are placed larged thumb nuts easily adjustable by hand. It is possible to do this on the road while tbe car is running. The brakes are of the same size as before, but tbe leverage has been increased by changing the position of tbe brake shoe and band operating lever. Formerly the brackets supporting these levers were of such design as to limit their backward movement. The brackets have now been hollowed out, so that when at rest the brake levers stand at an angle of 45 degrees to the rods.

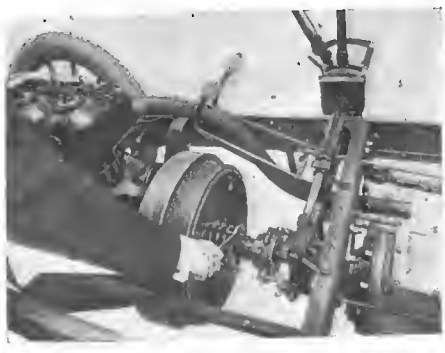
Few Changes in the Running Gear.—The Rambler screw-and-nut steering gear, tested by six years of service, is used again this year. The parts are heavier, and better provision is made to guard against and compensate for wear. Downward thrust is taken up by a ball tbrust bearing located at the top of the steering column. Wear in the gear itself is guarded against by the use of a hard bronze nut, instead of babbitt as before. The steering arm is carried well out to the frame, so that the connecting link does not interfere witb the mud pan.

For some time the Rambler company has been trying to obtain a rear spring for the four-cylinder models which would provide as great flexibility as any other type and retain the advantages of low center of gravity and absence of side sway peculiar to the semi-elliptic. Tbe desired qualities have been attained on the new models by springs known as "triple action." Besides the flexibility provided by the auxiliary coils, these springs are unusually long and have all tbe advantages of the semi-elliptic. Tbey have been thoroughly tested on a number of cars of the 1908 model.

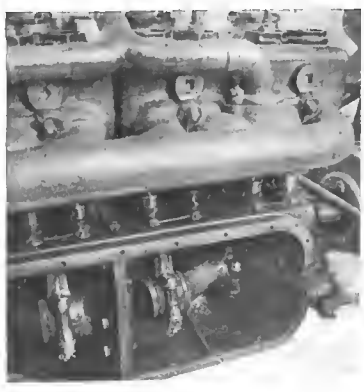
Features of the Two-Cylinder Car.—The Rambler two-cylinder models will consist of a five-passenger touring car and two or three-passenger runabouts, listing at from $1,150 to $1,350. Very little change has heen made from former models. The unit power plant, with the change-gear, clutch and flywheel enclosed, is continued in exactly the same form. The body is arranged to tilt upward to give access to all working parts in the motor and transmission. The main crankshaft bearing is of the self-centering type, and adjustment is accomplished by turning in a ring which draws the two halves together in a tapered box.

An unusual feature for a two-cylinder car is the floating type rear axle. The weight of the car is carried on heavy roller bearings, located on the axle tube, the driving shafts being relieved of all weight and serving simply to rotate the wheels. The aluminum rear axle housing formerly used has been replaced by a heavy forged yoke. The clearance of this car is unusually large. The lowest part of the mechanism is the rear sprocket, and as this is located to one side of the center, it clears obstructions which centrally located sprockets would encounter. In addition, the rear wheels are 34 inches in diameter, so that there is a distance of 15 1-4 inches from the ground to the axles. The tires are 34 x 4 inches and the wheelbase 106 inches.

Showing the New Plug Connectors.



Simplicity of the Rambler Clutch Adjustment.



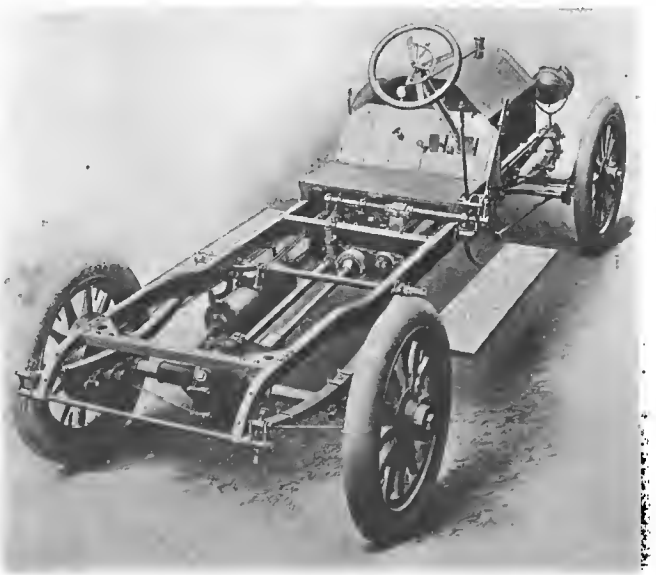
Rambler Main Bearing "Get-at-ability."

Locomobile Shaft-driven Model for 1909

By Charles B. Hayward

BRIDGEPORT, CONN., Oct. 26.—There will be a shaft driven Locomobile for the 1909 season, and, while this nouncement of the builders may come somewhat as a surprise dvocates of the chain drive, of which the Locomobile Com- has been a most consistent advocate since the earliest days, ill doubtless prove more of a surprise to learn that Mr. r and his staff have been working on the problem of the t drive for more than three years past. From the very et the upholder of the chain type has looked with con- rable suspicion upon any construction which must at once the load of the vehicle and also act as a driving medium, it has been with the idea in mind of entirely eliminating disadvantages arising from the latter that the Locomobile pany has centered its efforts for so long a period upon a t-driven model without making it public. In other words, object has been to evolve a shaft drive that could be re- ded as on a par with the side chain and the dead rear , where safety and reliability are concerned. This the gners of the Locomobile feel confident that they have eved in the new Model L, and a review of its specifications ere set forth goes far onfirm it.

Details of the Power nt.—As is naturally to expected, the motor is racterized by the nu- ous details of design construction that have n worked out by Mr. er and his staff on the comobile cars in the t seven or eight years, that there is an utter k of anything that ght be termed radical, for that matter any- ng that is really a de- ture from what has g since come to be ognized as standard ctice on this car. The inders are of the "T," outboard valve port e, cast in pairs, with ge openings in the ads of the water jack- that are covered with bronze plates. The cylinder castings receive three boring cuts, and are then ground. The cylinder dimensions are 4 1-2 inches square, and the power rating nominally employed to distinguish the car is obtained at a low normal speed and is very conservative, as the motor has shown close to 40 horsepower on long-continued tests, made on an electric dynameter, an installation of several of the latter being used entirely in testing the Locomobile motors in the regular course of manufacture. The valves are oppositely disposed, and are driven from independent camshafts, the inlet shaft also carrying the igniter cams. The latter are made with a tapering face, and the shaft itself is so mounted as to permit of its being shifted longitudinally to advance or retard the ignition timing. Both of the camshafts are made with the cams integral, and are one-piece drop-forgings turned out in the home plant, the Locomobile Company having long been noted for the completeness of its drop-forging equipment. This method is employed for the manufacture of every part to which the process lends itself, ranging from the smallest fittings up to the one-piece I-beam front axles. All drop forgings are subjected to treatment.



Rear Quartering View of Model L, Illustrating Its Shaft Drive.

As has been the case for a number of years past, manganese bronze is still retained as material for the crankcase, the supporting arms for the motor being cast integral. The oil-pan is of aluminum, as is also the housing for the timing gears, neither of these members being called upon to sustain any load. Throughout the construction of the motor the most advanced practice is followed to insure accuracy and interchangeability, the cylinder, pistons, rings, crankshaft and camshaft all being ground to micrometer gauge, while such pieces as the crankshaft are all specially heat-treated, the Locomobile plant having a particularly elaborate and complete heat-treating and

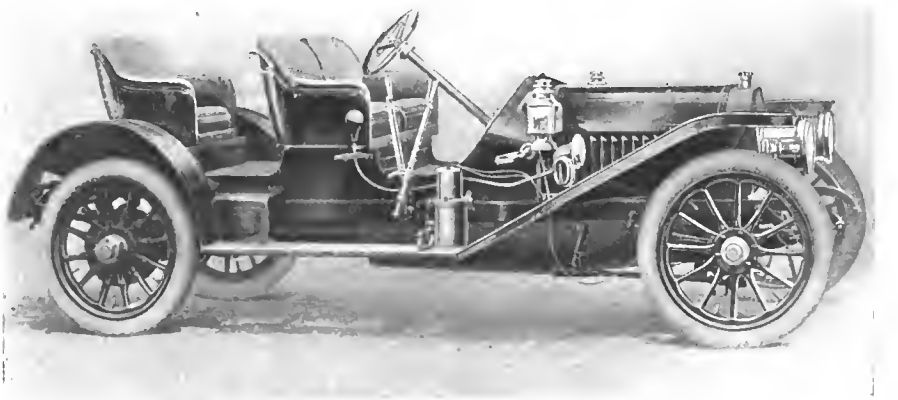
hardening department in connection with its drop-forging plant.

About the Motor's Accessories.—As has come to be recognized as the best standard practice in this respect, the oiling equipment of the motor has been made practically integral with the latter on the new Model "L." A mechanical force-feed oiler, having three direct leads to the main bearings, is situated at the rear of the motor, almost under the footboard, and is gear-driven from that end of the exhaust camshaft, the drive all being protected by an aluminum oil-tight housing. To facilitate the distribution of the oil, the crankshaft is drilled, while a hand pump on the dash is employed to suppplement the crank-case supply for splash lubrication whenever necessary. But one of the oil feeds is carried through a neat and very small sight glass on the dash, thus ridding the latter of what has long been regarded as an undesirable encumbrance.

The carbureter is of a special type that has been developed by the designers of the Locomobile during the past five or six years, and which for the coming season has undergone one or two changes. Chief among these is the adoption of water-jacketing, hot water being tapped from the top of the jacket of the rear twin-cylinder casting, and led between the latter and the forward pair to the carbureter jacket, the discharge from this being returned to the bottom of the radiator. Liberal sized copper tubing has been adopted for this purpose, and no flexible joints have been found necessary. Shut-off cocks are provided both on the intake and outlet to provide for regulation of the hot-water flow. Another entirely new feature of this carbureter is the conical tapered spring auxiliary air valve. This spring is carefully wound to a very closely predetermined tension, and is vertically placed directly above the throttle, which is of the piston type. An increase in suction above that normally taken care of by the main air inlet causes this spring to distend, thus permitting additional air to enter through the spaces between its coils. The piston throttle in question is controlled from one end by the usual hand lever on the steering wheel, while from the other it is regulated by a centrifugal governor incorporated in the exhaust camshaft-driven gear. This governor permits the motor to maintain any speed up to the point of throttle opening allowed for by the hand lever, while the accelerator pedal cuts out the governor entirely. The low-tension magneto of Mr. Riker's design, which has been a distinguishing feature of the Locomobile since 1905, is continued without any change whatever from the 1908 model, this also being the case where the igniter equipment is concerned, as this part of the car has been developed to a point which leaves nothing to be desired. A feature worthy of mention in this connection is the fact that the iridium steel contact points employed are now welded to their blocks, making them practically integral with the latter. Cooling is provided for by a centrifugal pump circulating the water through the honeycomb type of radiator that has long been a familiar Locomobile feature. This is supplemented by a belt-driven aluminum fan running on ball bearings, and for which an eccentric tightening adjustment is provided. Union connections are employed on the radiator, both top and bottom, and do away with the necessity of breaking hose connections when necessary to dismount any part of the cooling system. Both the throttle and spark control are effected through a screw and nut movement, instead of the bevel gears ordinarily employed, this making a considerable saving in space.

The starting crank spring, instead of being carried forward as formerly has been placed farther back, and is now completely housed in, giving this part a much neater appearance and protecting it from dirt.

Features of the Transmission.—The first step in the transmission of the power consists of the standard type of leather-faced cone-clutch, which, however, is so mounted as to be removable without altering the tension of its engaging spring, or, in fact, without disturbing any of its related parts. Flat springs are employed under the clutch leather, causing the clutch to engage smoothly and without jerk. No universal has been found necessary between the clutch and the gear-set, the latter being placed about in the same position in the car, as was the case when it was chain-driven. The gear-set is of the sliding type, providing four forward speeds, with but two, instead of the usual three, sliding members. Both shafts are mounted on imported annular ball bearings, and the entire gear shifting mechanism is enclosed in the same housing with the driving gears. The use of but two sliding members to effect the gear changes permits of the use of a much simpler sector. Direct drive is on the fourth speed. The housing of the gear-set is of



Attractive Lines of the "Thirty" Locomobile Roadster for the Coming Season.

manganese bronze, with an aluminum oil pan, following out the same construction as characterizes tbe crankcase.

Drop-forgings enter almost entirely into the makeup of the shaft drive, and are also a prominent feature of the differential and rear axle. The forward universal consists of two drop-forged yokes, the pins of which are bronze-bushed, while the latter are clamped with steel rings in order to permit of taking up any wear that may occur, although the experimental cars of this type that have been on the road for almost 10,000 miles show no signs of wear whatever in this essential. At the rear end of the shaft there is a combined universal and telescope joint, consisting of an extended drop-forged yoke in which a substantial pin is free to move longitudinally on rollers, the latter being hardened and ground, as is the case with all load-carrying parts. This yoke of the universal joint is in one piece, with the shaft carrying the driving bevel, and is supported on an annular ball bearing besides carrying a special thrust bearing of the ball type, which is placed directly behind the universal. There are several features of interest in connection with the use of the annular ball bearings on the Locomobile, a great deal of care having been taken to mount them exactly in accordance with the maker's specifications. For instance, the races of the forward bearings in the gear-set are rigidly held, while the after one is allowed to float, thus permitting the bearing to center itself accurately. This is also true of the ball bearings used on the driving shaft of the live axle. All are of unusually large sizes for the loads to be carried, providing a very high factor of safety where these important essentials are concerned. A ball thrust bearing is placed on each side of the differential and annular ball bearings are used for carrying the rear wheels. The driving shafts are one-piece drop-forgings, and are made integral, with heavy flanges on their outer ends from which the wbeel-driving clutches are milled, the specifications of the latter calling for their engagement with the corresponding member on the driving wheel to .0001 inch. The standard gear ratio is 3.24 to 1.

Brakes of the "Thirty" Locomobile.

Doubtless the most interesting feature of the construction of the rear axle is to be found in the fact that the housing of the driving shafts is designed merely to carry the dead load of the car and its passengers, and is not subjected to either braking or torsional strains, this being a feature that has come in for all too little attention on a great many American shaft-driven cars. The axle tubes are seated into the central housing by hydraulic pressure, and are then riveted in place. They are braced by means of a substantial strut rod made with a ball seat head forged integral with the rod. The same drop-forged distance rods that have always characterized the chain-driven car are employed, and are designed to take the entire braking strain, the springs being revoluhly mounted on the axle tubes and shackled at both ends. In the design of the axle tubes particular care has been taken to eliminate all shoulders, changes in diameter being made by gradual taper.

The brakes measure 14 incbes in diameter by 1 1-2-inch face, and, instead of being mounted concentrically, are placed side by side in a large drum housed in by a plate carried on the distance rod. Small yoke equalizers are employed on both the emergency and running brakes, thus dispensing with cables. The brakes are cam-operated, the shafts being concentric, and are lubricated by a compression grease cup, as is the case with every other moving part of the car outside of the motor and gear-set, no less than 28 of these cups being provided on such parts as the spring shackles, steering knuckles and the like. Further evidences of the painstaking care used to provide proper lubrication is to be found in the fact that the spring leaves are all graphited before assembling. The rear springs measure 48 inches by 1 3-4 inches, while the forward ones are 36 inches long, of the same width. In drop-forging the saddles for the former, an extension has been placed on them to provide a lifting point for the jack—an addition that has been found very convenient. The steering gear is of the worm type, a full worm wheel being employed instead of a sector, thus providing a means of taking up wear by bringing an entirely new gear face into contact. The front wheels are carried on Tinken roller bearings; the wheel base is 120 inches and the tread 54 inches, tire equipment consisting of 34 by 4-inch front and 34 by 4 1-2-inch rear, the make being optional. The new model will be listed at $3,500.

THE IMPORTANCE OF HAVING GOOD BRAKES

By ARTHUR H. DENISON.

It is never worth while going out with a car unless the brakes can be depended on. Accidents are costly, as well as dangerour to life and limb. When the car is not equipped with an equalizing device that will insure equal braking effort on both wheels, the best method of equalizing the brakes is to jack up both rear wheels together and adjust the brakes by hand as near alike as possible. Then have someone apply the pedals similar to running conditions and try to turn the wheels separately by hand. If the brakes are not adjusted alike it is easy to adjust either so that the braking effort is uniform. Also see that the brakes do not drag and waste power. Some brakes are intended to be lubricated, others are useless if oil gets on the friction surfaces. When this happens the best thing to do is to squirt a little gasoline on the drum. This will cut the oil and restore the efficiency. If one brake is adjusted tighter than the other it will throw the end of the car on tbat side around. Brakes should never be applied too bard. If the wheels are locked, much of the retarding effort is lost and much rubber is ground off the tires, or if traveling on muddy roads or pavements all control over the car will be lost. Friction surfaces of metal to metal, or steel to camel's hair or asbestos, will give little trouble with ordinary care. If leather is used, its life will be prolonged by releasing the brakes for an instant while in use. This will allow a current of air to pass between the surfaces and carry away a great deal of the heat generated. The friction of the brake leather on the drum always generates heat, and the leather may be heated enough to be burnt or charred until useless.

On long grades the brakes should not be depended on to hold the car. The ignition should be cut out, and, depending on the length and steepness of the grade, a suitable gear should be meshed and the car allowed to coast under compression, the brakes supplying any further retarding effort necessary. The writer, handling a 50-horsepower car that loaded weighed over 5,000 lbs., has brought the car to almost a complete stop from a speed of about 15 miles per hour on a 20 per cent. grade, by dropping the clutch in with the engine dead, first speed in mesh, and the energy required to bring the motor to the speed of the car was enougb to bring it to almost a dead stop. This is a greater retarding effort than could be obtained by the use of brakes. Motorists driving in a hilly country should *never* have the emergency brake lever *interconnected* with the clutch, as this prevents the use of a very efficient brake.

The Foreign Automobile Tour from a WOMAN'S Point of View

By BLANCHE McMANUS

[ERE are many women, and men, too, who visit Paris, take a turn or two in the Bois, a few rides out over the execrable rban *pavé* to Versailles, Saint Germain, and Fontainebleu, that is all. These suburban Paris sights many people think must enjoy and take in because they are classic, and because have been told that the roads leading thereto are the over which royalties one day rolled in bone-shaking state ies, and did not mind in the least because they never even cioned the advent of the automobile. The horseless carriage nds something more than Louis Quatorze *pavé* in order to l in comfort. It is these folk who do their automobiling id Paris who go home and tell of the "lovely time" they had ing in France." Some may even get so far away from apital as to spend three or four days in what has come familiarly known as "the châuteau country," dividing their between the big botels of Orleans, Tours and Nantes, and how châteaux.

e instinctively puts France first where automobile touring icerned, for where one woman is seen on the road in other ries there are hundreds in the land of good cooks. The l of show places and big hotels is enjoyable enough in e, at least more so than elsewhere, but the open road s for much more. It means the long run across country g some little country hotel early in the morning, so early, imes, that even the *garcon d'ecurie* is not yet about, and s obliged to open the *grande porte* of the courtyard one's order to get out into the open. This presumes, of course, ne has taken the precaution to pay his reckoning the even- fore, and, being in a considerate mood for the feelings of people, takes care also to push his automobile into the and start it there rather than fill the small courtyard with and noise and the ire of the sleepy inmates of the house. these little courtesies that smooth the way of the auto- st, but not everyone thinks of them at the right time, of all, milady, who, for a fact, often thinks she is doing ody about the place a favor by condescending to have in such a humble establishment, where she has to retire light of a candle, as she most likely will have done if she ly touring and not flying willy nilly, humming-bird fashion, one electric lighted resort to another.

knobbly *pavé* of the village is soon over and your auto- swishes along the smooth white road between dewy fields the industrious peasant—invariably an early riser in —is already at work. The sole occupants of the road time, other than yourself, are great farm horses with lumsy carts and drowsy drivers, and they, too frequently— nce as elsewhere, alas!—on the wrong side of the road. should cultivate the habit of the early start, perhaps the rying of all automobile habits for womankind. One soon learns the wisdom of it, however. If you are going to have trouble with your machine en route, it will come early in the day, and then you will have some chance of getting over it before night.

Breakfast in bed—even a continental breakfast—followed by a dawdling toilette often finds you at night with a lame and limping automobile, and you, like the foolish virgins, may be forced to remain without the gates with no oil in your lamps. An hour or so of this early morning run and then comes the stop at some little wayside café for an unconventional breakfast of a cup of coffee and a roll, and as you drink it in a little vine-covered arbor, or on some hillside terrace, you will not regret the lost breakfast in bed, with the almost invariably bad hotel *café-au-lait—a rechauffée,* simply of the coffee of the night before.

Many tour thousands of European kilometers without maps, without once slackening speed at any of the excellent and obvious road signs scattered up and down the continent, and are proud of it. Their unhandy method is to harry the good-natured natives along the road, but then one only gets dubious information at best, for the native himself usually doesn't own an automobile and his own radius of action is always very limited, and his knowledge of roads and routes likewise. A conductor of an automobile such as this eventually loses his temper and everybody suffers.

Ideal Foreign Tour Not a Dress Parade.

The ideal tour isn't a dress parade, and it should not be made to include the resorts of the big hotels whose *salons* are the showrooms of the *couturiers* and *modistes* of Paris, London and New York. If the glamour of the grand hotel tour is too strong to be resisted, why go in a big limousine, top-heavy with luggage, trunks and hat boxes, if you will, but be consistent, at least, and don't try to mix vagabondage and super-luxurious travel. The woman who is always talking about how she "loves those quaint little country places where one doesn't have to dress, you know," has invariably excellent reasons as to why she is never found at any of them, and has her name cabled frequently to her home paper as having arrived at the Grand Hotel this or that at Trouville, Aix-les-Bains, Cadennabia or Biarritz. If by any chance one of these flighty, unknowing persons is ever induced to sample the delights of the simple country inn, her chagrin and weariness are painful to observe.

It is not necessary for a woman to always have by her a trunk filled with what she sometimes calls Monte Carlo clothes in the hope that she will be able to induce her husband to pass that way. It may be well to remark right here tbat no Mediterranean Winter resort has a climate which warrants the wearing of indiscriminately thin dresses.

The modest suit case will not debar one from the enjoyment of Europe's great pleasure resorts. It is just as easy to enter the *Salles des Jeux* at Monte Carlo, and amuse one's self in losing or winning a few or many five franc pieces, or "louis" for that matter, and one may lunch at Ciro's as much at ease in the simplest traveling dress as in the latest Parisian confection, though, perhaps indeed they will not be so conspicuous. It is true that on entering the Casino at Monte Carlo the woman automobilist, who is still shrouded in a veil, will be asked to take it off before entering the *salles*—this for some occult reason known only to the administration.

You may even rub shoulders with Kings Edward and Alphonse at Biarritz in the same democratic garb in which you do your automobiling, as you "five o'clock" on the hotel terrace. They will, most likely, be dressed in the same sensible fashion.

If one should foolishly lumber up their automobile with much baggage, not many, even with the best intentions in the world, will bave enough energy left to make any radical change in their dress when finally they reach the night's stopping place.

On this basis one's preparations soon dwindle down to a change of stock, a hasty brushing off of dust, and a generous

polishing of hands and face so that when the big bell in the courtyard sounds for dinner, one descends to the *salle à manger* much too healthily fatigued and hungry to even care to explain why she hasn't "dressed for dinner."

Don't Be a Fault-Finder; It Doesn't Pay.

It will avail nothing to bolt into the English country inn, French hotel, or Italian albergo and adopt an air of criticism the first thing, as if you were about to plan the reconstruction of the establishment according to your own preconceived ideas. One only gets disliked for this and accomplishes nothing except to upset the ménage and add to discomforts already existing.

Don't try to have a course dinner served to you all at once, because you can't eat meat without vegetables, nor demand *café-au-lait* with the same repast unless you are prepared to astonish the natives and pay, say, a franc and a quarter extra for each person. All these things only bewilder the *garçon*, excite the *chef*, and spoil what would otherwise have been a good dinner.

What is the use of calling the *bonne* to account if there is a bit of fluff on your bedroom floor so long as the beds are clean and good, as will most always be found to be the case even in the most modest of European hotels.

Make up your mind before leaving home to do without bathtubs. In England the exaggerated flat tin dish that answers to the same name as our best porcelain in America is no better suited to its purpose than the more limited accommodation one usually finds in France and Germany and Italy. The dust of the roads comes off no better in one than the other. The only way to get it off is to lie down and soak it off, and there are very few opportunities for that in Europe outside of the great capitals and the frankly avowed resorts with a stranger clientèle.

The substitute is the jugs of water, which, on account of their diminutive size, are brought by many journeys of the willing *bonne* or *madchen*, or, in France, as is most frequently the case, the service will be performed by a *garçon*—a man in other words, though do not let this shock your womanly sensibilities. It is the *garçon*, a man of all work about the house, that in France, more often than not, performs the functions in the small hotel in the small town which are usually delegated to a *femme de chambre* elsewhere.

Hunting for Hotels with Bathtubs.

There is a largely increasing class of travelers wandering up and down Europe, who spend a good part of their time on a still hunt for hotels with bathtubs and "hot and cold water laid on," as the English have it. This brings dismay to the ordinary European hotel-keeper, to whom a single *salle de bain*, accompanying a score or two of sleeping rooms, is already considered as the acme of an unnecessary and luxurious appointment, and one on which he is loth to spend more money to provide a further installation. Therefore, the private bath is practically non-existant off the beaten tracks, and the common public affair, even, is a great rarity.

The wail of these good travelers who would demand a bathroom for their own use if they were in darkest Africa goes up continually in a loudly increasing scale from London to Cairo and from Paris to Rome. It forms one of the principal topics of conversation, where women tourists mostly congregate; this, regardless of the fact that with many must still linger the remembrance of the good old-fashioned Saturday night scrub which they took in the family wash-tub before the kitchen fire. Porcelain tubs and hot and cold water led up thereto in nickeled piping didn't arrive with us at the same moment that the Mayflower set down its array of ancestors on Plymouth Rock.

When Women Are in the Party.

The very fact that an automobile touring party counts women among its members is often an excuse for the European hotel patron to press upon his guests the use of small tables in the dining room (at fifty centimes or a franc extra for the repast and *vin non compris*) or an even *salle particulière*, as being more exclusive than the ordinary table d'hôte, and, therefore, what you are looking for. You are probably not looking for this sort of thing at all, but he thinks you are. Why the automobilist should be put into a class by himself is not quite clear, and should be discouraged by the woman automobilist who is largely responsible for this invidious distinction. It's more expensive and less amusing from every viewpoint.

The day when automobiling can properly be considered a society function or the *jeu* of millionaires and heiresses has happily passed, so don't hesitate to take your seat at table d'hôte, for the dinner is just the same as would be served at small tables and the price less. The establishment could not vary its menu in many cases if it would, save to add a tough *bifteck* or an *omelette au jambon* always given *"les étrangers"* if they will stand for it, even if you are, as will often happen in the country town, the only woman present. At the long table in the center of the *salle à manger* you will not be annoyed by unduly inquisitive stares or comments on the part of the other diners, not half so much as will be your fate if you sit apart. The provincial European, the Frenchman in particular, especially when occupied with his dinner, preserves an almost Oriental oblivion to the presence or even existence of woman.

It may be that in your tour across France en automobile, when you have reached the little town where you have elected to pass the night, it happens to be the eve of market day, and as you drive noisely into the courtyard of the principal hotel you find it crowded with farmers' carts and wagons of all ranks of distinction and size. What difference ought it make to you if you are put to sleep in the only vacant rooms which remain, those running along one side of the courtyard over the stable, and to which you mount by an outside stairway and an open air gallery? It's all in one's book of experience, and so long as the rooms are clean and the dinner good (which you will eat in company with the prosperous neighboring country folk there assembled) you will be better content when it is all over than you most likely would have been had you kept on to some big town and been served imitation Parisian fare.

Another Leaf in Experience's Book.

The next night, perhaps (and here's another leaf in the book of experience which you will reread with pleasure at some future time) you will find yourself housed in some aristocratic old hostelry which claims the local noblesse for its clientèle, as it did in the old posting days of Le Grand Monarque. Here you may sleep in a princely bed of inlaid woods, draped with silken hangings. This thing may happen on anybody's "little tour in France," and they, and others, not far different, are what make the charm of French travel. One of the greatest of these is the thing that one falls upon unexpectedly, a quaint inn, a remarkably good dinner, or a bit of local color that looks as though it might be a part of a costume novel.

The automobile tour demands that one and all who make the party should preserve their equanimity; the troubles of the road only serve to accentuate one's pleasurable experiences, and, after all, those are the things which will be most deeply etched on one's consciousness. Troubles are more readily forgotten than pleasures. Women are too prone to think that their way is only smoother for them by the lavish expenditure of money on the part of their male relatives. Something besides money talks, fortunately, when touring in France.

Little politenesses count for much among the older nations, often for quite as much as the indiscriminate throwing around of coin, though it may be difficult to convince some of this. The average person abroad who caters for travelers is not nearly so grasping, if approached in the right way, as is commonly supposed. So scatter a few smiles and appreciative words along with your louis, francs and sous.

Always shake hands with the French country hotel landlord on leaving if you have stayed longer than a single meal (never this thing in England; they would have a very poor opinion of you if you did it). Nothing pleases the patron of the small French hotel so much as this little attention—and you leave behind the verdict, *"Les dames Americaines sont toujours gentilles."*

VANGUARD OF GRAND PRIZE DRIVERS DUE THIS WEEK

WITH the Vanderbilt race over, the scene of 1908's great Autumn road racing campaign shifts to Savannah, where on Thanksgiving Day will be run the international Grand Prize contest for the Automobile Club of America's gold cup, with a light car race the day before by way of a curtain raiser.

The first of the foreign drivers arrived Tuesday, they being Cagno and Piacenza, of the Itala team. Fournier, the other member of the trio, will not reach here probably until next week. Nazzaro and Wagner, of the Fiat team, are on the *Lorraine*, due on Saturday, on which Hautvest and Rigal, of the Clement-Bayard, and Duray, of the De Dietrich, are also reported to have sailed. Szisz, the Renault pilot, will sail this Saturday on the *Touraine*.

The entry list for the light car race is growing rapidly and on Tuesday had reached 21. Two more Buicks have been nominated, raising that factory's string of candidates to four. Late entries include three Oldsmobiles. Their nomination by the Olds Motor Works is noteworthy in that it marks a re-entry of Oldsmobile cars into the racing game. Besides this, this race will be the first competitive, and, in fact, public demonstration of the new $1,200 cars this company is to put on the market. They will have 3 3-4-inch cylinders. It is expected that William Folberth will be the pilot of one of them.

Entries for the Grand Prize and light car races will close finally next Monday. The headquarters of the club's contest committee will be transferred to Savannah, October 15, when Chairman Morrell will take up the preliminary local preparations for the races. N. H. Van Sicklen, of Chicago, who was prominent in the management of the March races, will go to Savannah next week to again assist the local clubmen.

QUAKERITES HAVE GASOLINE-ELECTRIC STOP-WORK TEST

PHILADELPHIA, Oct. 26.—Thursday afternoon last there was quite a little flurry of excitement all along "Gasoline Row" over an impromptu contest between an electric and a gasoline —both of the Studebaker brand—which was pulled off to decide a heated discussion as to the relative merits of the two powers in short-stop work in big cities.

It was agreed to make up a list of 25 calls, with instructions to each driver to make one-minute stops at each place, and shutting off and starting up the power at each stop; one driver to begin at the top of the list and the other at the bottom. The electric bunch, just to prove that they had no fear as to the outcome, put a lady, Miss Laura Duval, up as driver, while the big seven-passenger gasoline car was handled by Tom Middleton. The latter was off like a flash when the word was given at 2 o'clock sharp, while Miss Duval proceeded more leisurely down Broad street on her mission. There was a wait of a few minutes over an hour when the electric was sighted homeward bound. Miss Duval drew up at the curb at exactly 3.10, while it was a trifle over ten minutes later when Middleton brought the big gasoline to a stop. "Tom" was hot and flustered-looking after "cranking up" 25 times, while Miss Duval finished as cool-looking as a ripe peach in a refrigerator.

Besides the time gained in starting, Miss Duval said she had lost little time in threading the maze of traffic on Chestnut street, her little car enabling her to worm in and out and around standing carriages, wagons, and trolley cars, while the big car was often held up until an opening was made by the starting of the car, wagon, or other obstacle. And yet, despite the "I-told-you-so's" of the electric enthusiasts, the gasoline didn't seem to be convinced.

MARYLAND'S AUTO MEASURE READY FOR LEGISLATORS

BALTIMORE, Oct. 24.—A bill to be presented to the next Legislature has been framed by the automobile commission of this State which will bring in $75,000 a year for use in creating and maintaining good roads, in addition to the $5,000,000 loan which was passed by the last General Assembly. The plan of the commission is to tax cars according to horsepower, the rate being from $10 to $25. Two thousand high-grade cars paying the maximum of $25 a year would make $50,000.

There are altogether 5,500 cars throughout Maryland and the commission says the amount realized in taxes on the remaining cars would make up the other $25,000. This amount would be used in opening up and maintaining improved highways, and this plan, the commission figures, would encourage more people to buy autos, with the result that the number of machines would be vastly increased. The present auto tax is $3 and is perpetual. The commission will recommend in its bill a liberal but not reckless speed law, and will also insist upon chauffeurs being licensed.

DISCRIMINATES AGAINST SMALL CAR OWNER.

BOSTON, Oct. 26.—The Metropolitan Park Commission, which controls most of the parkway approaches into Boston, and which last spring barred from its roads all sorts of tire chains, studs, burrs, and other metallic anti-skidding devices, has announced a change of the rule to go into effect on November 3. There were loud protests from autoists when the rule was put into effect, and as a result the commission watched very carefully its operation. As a result it has decided that after November 3 armored tires will not be prohibited, but that the rule against tire chains shall be enforced and also that the use of ropes of metal or other material on the wheels shall be under the ban. It is not admitted that armored tires do not wear the roads, but that they wear less than chains or ropes.

BALTIMORE WILL HAVE A HILL CLIMB.

BALTIMORE, MD., Oct. 24.—The Automobile Club of Maryland, through its committee on contests and exhibitions, has formulated plans for a hill climb in compliance with A. A. A. rules. The time set for the contest will be either on or within a few days of Thanksgiving Day. Dr. H. M. Rowe, president of the club, has offered a president's cup and Thomas G. Young has also donated a trophy to be given to the winner.

FORT GEORGE HILL CLIMB AGAIN POSTPONED.

Another postponement of the Fort George hill climb, scheduled for Election Day, has taken place. It was found that the competing cars would pass a polling station and possibly interfere with the rights of the voters.

AMERICAN CAR AND AMERICAN DRIVER.

Differences of opinion may have existed as to the worth of the rules to the industry itself, not a few of the cars engaged may have been two-year-olds and constructed for speed solely, and the field may not have classed as high internationally as those of previous races, but the fact stands out clear and distinct that an American car, made entirely of American materials, and driven by an American, convincingly won the fourth contest for the Vanderbilt Cup, a trophy that now stands by itself in the estimation of automobile owners and makers.

All comes to him who waits—and works while he waits, so that he may be prepared for that which he waits when it arrives. This applies to the company which produces the Locomobile, for it built two superb racing crafts for the 1906 Cup race. One of these was used, and made the fastest lap of the day, but an insufficient practice period failed to disclose minor defects that betrayed themselves in the race itself.

Nevertheless, the designer, and others who had opportunity of obtaining exact knowledge, believed that the two cars were equal in speed to any ever built here or abroad. Naturally, the maker wanted further to utilize the results of his skill. Unfortunately, there was no race in 1907, owing to inability to secure a properly guarded course. (How can we obtain one in the vicinity of the metropolis, unless an iron fence, spike-topped, be stretched around it?) It is now an admitted fact that the 1908 rules, at variance with the international regulations, proved detrimental in assembling a more international entry. At the same time, though the French Grand Prix cars had lesser bore, their makers had retained as much horsepower as before by the simple expedient of lengthening the stroke, for there was no maximum weight restriction.

If the big club in New York City had not in the struggle for the retention of its "foreign relations" forced the European clubs to observe scrupulously the Ostend agreement, it is a certainty that the bore difference would not have kept the Grand Prix cars out of this year's Vanderbilt. However, that is an old story, the sequel of which is scheduled for Savannah on Thanksgiving Day.

Hence again to the Vanderbilt. The American winner met three Germans and two French cars of unlimited bore and stroke, and trounced them aplenty. And right here it should be said that the single Italian participant, with its lesser bore and stroke, made a consistent showing for which it should receive a goodly amount of credit, though it should be mentioned in the same breath that an American driver was at its wheel.

The intractable American crowd surging upon the course as soon as the American-Italian duel had terminated, prevented other cars from finishing, though it is good figuring that No. 1 Locomobile was entitled to third place in front of a Mercedes, behind which another American, a Thomas, was progressing homeward.

In the showing of the Chadwick six-cylinder there is something more in which America can take additional pride, for it led three laps and lost its grip of the situation, not owing to troubles of its stock engine, but because of ignition difficulties. Its engine meets international conditions, and 'tis said may participate at Savannah, with the Grand Prix invaders.

It has been one of the faults of American makers to delay preparations for racing until the eleventh hour, and then expect to hold their own with the creations of European manufacturers who have carefully planned a year ahead and left undone nothing which might seem to insure success. It is pretty good guessing, however, that this time the Locomobile candidates were ready and waiting for the starter's gun, even though there was some uncertainty as to the men who might be placed at the steering wheel. And therein lies another reason why we in America have been sadly at a disadvantage in high-speed competition. Our drivers have not had sufficient opportunity to try out their cars in such manner as their French and Italian rivals, who have miles of practically untenanted roads where speed is reasonably interpreted.

The building of the Long Island Motor Parkway unquestionably will greatly aid in lessening this handicap in the future, for certainly it will provide a place for trying out a car to its full capacity.

All in all, the 1908 Vanderbilt race, despite its deficiencies, is an event calling for American enthusiasm and American confidence in future international competition, the life of which may not be very extended in automobiling, owing to the inevitable growing unproductiveness of the American market for the foreign makers, who will not race here when they cannot sell here.

About the Winning Car and Its Driver

TEREST naturally attaches to the mechanical details of the winning car, for in these days of strenuous competition, :n the loss of but a minute or two means dropping back into :c, instead of achieving the covcted first, the specifications of design and construction that withstood the gruelling test iout a falter and came through with flying colors are matters import. Robertson's Locomobile, which ran as No. 16, and rida's No. 1 Locomobilc are the twin cars designed and t especially for the Vanderbilt Cup race of 1906, and with exception of a few minor changes, such as the substitution a selectively operated gear-set in place of the progressive type merly employed, they have not been altered.

n the light of the present tendency to limit motor dimen-is, the Locomobile's cylinder dimensions of 7 1-4-inch stroke 6-inch bore appears very large, but the object under the 's formcrly prevailing was to construct a motor of the ximum size, consistent with the minimum weight limit of o kilos. The cylinders are cast in pairs with the water-:ets integral, but the latter are largely cut away, the open-; being covered with light plates, to save weight. The inlet :e is placed in the head and the exhaust on the side, both g operated from the same camshaft.

or ignition, a special low-tension magneto, made from speci-ions by Mr. Riker, the designer of the car, is relied upon :ely, the ignitors being exactly the same as the stock Loco-iles, as, in fact, is the case with many of the other features he car. The clutch is of the conical type with the usual ier face and is held in place by six dowels when home. remainder of the transmission is composed of a three-speed tively operated transmission and double chain drive. Both : and rear axles are one-piece drop forgings of the I-beam The wheelbase is 110 inches.

Interesting Racing Career of the Pilot.

orge Robertson, the winner, is a New York boy. In build a giant. In age he is not so very far into his "twenties." first introduction to automobiles came through association isiness with his father, who, in the days when the short on Thirty-eighth street between Broadway and Seventh ie was New York's "automobile row," established there Automobile Exchange." He early acquired a reputation as d and rather reckless driver. When he took to racing he romptly included among the ranks of the daredevils.

well earned the soubriquet when he was entrusted with ilotage of the first Apperson Jackrabbit when it was en-for the Vanderbilt Cup race of 1906. His preliminary :e for the elimination trials of that year was a series of ional drives that got him wide publicity in the newspapers nally landed him against a telegraph pole with an utterly ed machine that robbed the Appersons of their chance for anderbilt Cup of that year or even a place on the Ameri-am. His first long distance race was in the second s Park 24-hour race of last autumn, in which he alter-nated with "Al." Poole in driving the Simplex. His mount finished seventh with a score of 696 miles. In April of this year came his first road race, the Briarcliff. In this he had the mount on Andre Massenat's Panhard. Though his car was still running at the finish, it had completed but six laps and was sixteenth in line.

The Jamaica straightaway trials this Spring found him at the wheel of the Fiat, but the sprinting honor of the day went to Kilpatrick and the Hotchkiss. Again in the Lowell road race on Labor Day he was entrusted with the driving of a Fiat, which finished fourth to the Isotta, Locomotive, and Knox.

In the first of this year's Brighton Beach 24-hour races, Robertson shifted again to the Simplex, and, alternating at the wheel with Lescault, finished fifth, after having led in record time during the third, fourth, fifth, and sixth hours.

This ended Robertson's apprenticeship of wholesome defeats, which had taught him conservatism and caution and that the race is not always to the swift. His victory in the Simplex in the second Brighton Beach race in track record time, and his triumph in the Founders' Week 200-mile race at Philadelphia, both of which occurred this month, are recent history and formed brilliant tryouts for his final winning of the classic Vanderbilt.

Robertson's stop on the last lap had much of the sensational about it. It happened at a series of sharp turns near Bethpage concealed by woods, where the only warning was the noise of the racer. The Locomobile swung around one of these turns at top speed, skidded and turned completely around, ripping off the tire. Robertson won the admiration of the crowd by his coolness in the emergency. He took but 2 min. 10 sec. to put on a new one.

Trade Camps on the Course.—There were several noteworthy trade camps along the course. The Maxwell-Briscoe Motor Car Company and the White Company, with Benjamin Briscoe and George W. Bennett playing the part of head hosts, had big parking spaces, where they hospitably entertained the users of their cars. Mr. Briscoe also made the occasion a veritable reunion of Maxwell agents. The camp was in telephonic communication with the grandstand, so that all hands were informed of the progress of the race. The White people paid particular attention to the entertainment of newspaper men. In fact, that brought over from Philadelphia the "Shock Absorbers," an organization of automobile journalists, and kept them over night in its tent.

The Matheson Automobile Company, the American Locomobile Company, and the Peerless Motor Car Company were among the other prominent makers to establish parking spaces along the course.

Isaac H. Cocks established a parking space as a charity enterprise and netted thereby $450 for the Children's Home at Mineola. Scores of farmers reaped a harvest by turning their fields into parking spaces and renting privileges from $5 to $10.

Things in General about the Race

A. A. A. Notables Much in Evidence.—From various parts of the country came directors and officers of the A. A. A., the Racing Board of which practically supplies the Vanderbilt Cup Commission. The list of those present included the following: Robert P. Hooper, president Pennsylvania Motor Federation; Powell Evans, president Automobile Club of Philadelphia; P. D. Folwell, president, and Richard Sellers, Quaker City Motor Club; Edward Kneeland, president Automobile Club of Pittsburg; F. A. Godcharles, Automobile Club of Central Pennsylvania; Oliver A. Quayle, president, and C. D. Hakes, secretary, New York State Automobile Association; F. B. Hower, president Automobile Club of Buffalo; W. L. Brown, ex-president, and Burns L. Smith, Automobile Club of Syracuse; George B. Baird, president Oneonta (N. Y.) Automobile Club; W. W. Brown, president, and Col. W. D. Woolson, Automobile Club of Vermont; Lewis R. Speare, first vice-president A. A. A., Boston; J. P. Coghlin, president Worcester Automobile Club; W. H. Chase, Wachusett Automobile Club, Fitchburg, Mass.; G. H. Gillette, vice-president Automobile Club of Hartford; H. D. Holbrook, president, and G. E. Cole, treasurer, Litchfield County Automobile Club, Torrington, Conn.; Ira M. Cobe, president Chicago Automobile Club; George G. Greenburg, secretary Chicago Motor Club; James T. Drought, secretary Wisconsin State Automobile Association; LeRoy Mark, secretary Automobile Club of Washington, D. C.; W. C. Crosby, president, and H. A. Bonnell, secretary, Associated Automobile Clubs of New Jersey; J. H. Edwards, ex-president Automobile Club of Hudson County, N. J.; F. B. Moore, Automobile Club of Mercer County, Trenton, N. J., and a host of other club members.

Difficulties of Guarding a Metropolitan Cup Course.—A New York crowd has no reverence for a mere show of authority, as was evidenced by the actions of the horde in the vicinity of the grandstand. Here the eager seekers for free vantage spots easily and without ceremony scaled the much touted wire barrier that was to afford a protected track. Not backed up by an army of guards, this fence might as well not have been there for all the barring it did of intruders on the course. The Pinkertons, deputies, and the Irish Brigade soldiers apparently were utterly insufficient in number or incapable for the purpose. The guardsmen that had volunteered to furnish the military feature of the track's protection paid more attention to cheering the racers and keeping their score cards straight than to the serious task they had undertaken. They were hardly a bit more efficient than were the soldier boys with their little sticks that afforded such humorous policing at the Briarcliff race. If it be impossible to secure State military co-operation in policing future Vanderbilt races, then it would seem necessary to erect a high, stout, barbed-wooden fence along the home-stretch, well guarded from invaders at either end, and leave

Industry Well Represented.—The automobile industry was well represented in the throng that saw the race. Among those to be seen were: E. R. Thomas and H. S. Houpt, of the E. R. Thomas Motor Company; S. T. Davis, Jr., A. L. Riker, J. C. Kingman, and J. T. Plummer, of the Locomobile Company of America; Paul LaCroix, of the Reuault Frères branch; Henry P. Joy, Russell Alger, and M. J. Budlong, of the Packard Motor Car Company; S. A. Miles, general manager of the N. A. A. M.; Alfred P. Reeves, general manager of the A. M. C. M. A.; E. P. Chalfant, assistant manager, and Coker F. Clarkson, of the A. L. A. M.; A. C. Newby, of the National Motor Vehicle Company, Indianapolis; John N. Willys, Overland Automobile Company, Indianapolis; R. M. Owen, New York City; Col. George Pope, Hartford; J. R. Maxwell and Benjamin Briscoe, of the Maxwell-Briscoe Motor Company; C. W. Matheson, of the Matheson Motor Car Company; Henry Ford and Gaston Plantiff, of the Ford Motor Company; R. D. Garden, New York Pierce manager; C. A. Singer, of Palmer & Singer; E. H. Brandt, Cadillac Motor Car Company; John Rainier, New York City; Joseph Gilbert, Continental tires; Windsor T. White, Cleveland; A. M. Robbins, Chicago; George Johns, A. H. Whiting, and a long list of others.

Auto Clubs Had Delegations.—Several of the largest A. A. A. clubs had special parties to the race. Nearly a hundred from the Automobile Club of Buffalo, with D. H. Lewis in charge, had a special sleeper from Buffalo, and it was sidetracked near the grandstand. Another carload came from the Automobile Club of Germantown, and this car was also tracked in the vicinity of the grandstand. The Automobile Club of Hartford had a run to the cup course, participated in by over two score of cars, and the party included Governor Woodruff, of Connecticut. Two large tents were erected for sleeping quarters at the club's parking place a short distance below the grandstand. The fact that a Nutmeg State car won the race could not fail to be a source of great satisfaction to the Connecticut contingent. The Long Island Automobile Club had a big parking space, near the grandstand, and it included a tent wherein refreshments were available to members and friends.

Building of Motor Parkway to Be Resumed Next Spring.—"The Parkway," said A. R. Pardington, "is a tremendous piece of work. It is wonderful to think that it was rushed through in only two years. They were two years of the hardest work of my life. Here we have nine miles fully completed and the rights of way for sixty more. Up to this time $900,000 has been spent, and there is $1,500,000 more to spend when work is resumed. And it will be spent. By this time next year the parkway will be completed to Lake Ronkonkoma, about thirty-five miles in all. We hope in time to hold such races as the Vanderbilt entirely on our own property."

Great Joy Over American Victory.—The enthusiasm over the race being won by an American car was sincerely and unmistakably shown by the wholesouled cheering at the finish. "I am glad an American car won," said W. K. Vanderbilt, Jr., to one of the first that shook his hand after the race. "It was a disappointment to lose," said Herbert Lytle, "but I am glad an American car won." "I'd give five hundred dollars to see that American car win," said Henry Ford excitedly in the midst of the doubt of the last lap.

Chadwick Ran Most Consistently.—The consistent and even running of the Isotta throughout was remarkable, but it did not compare with the consistency and evenness of the running of the Chadwick up to the time that trouble and disaster befell the American car. This is proved by Haupt's times for the first four laps, which were 21:29, 21:27, 21:26, and 21:36, an average that varied only a small fraction from 66 miles per hour each of these rounds.

It Was Tantalizing, Indeed.—It certainly was tantalizing to the man that came in an automobile to see that monster grandstand rising from out of the plain and then have to ride miles to find a road that might possibly lead to a path that might eventually get his car and passengers to the haven they were seeking. On that vast prairie there will certainly be plenty of land for the building of a loop when the parkway is completed.

Should Be Provision for "Bleacherites."—In discussing the mistakes and omissions of the first race over the parkway, Chairman Thompson said that one reason for the crowd's overrunning the homestretch was that no provision had been made to furnish moderate priced seats and bleachers for the general public. He thought that had the home stretch been lined with such seats there would have been little or no trouble.

Fooled by Headlights.—The search for the grandstand at night was a really serious matter for hundreds of automobiles. There were many advertising arrows tacked on the fences, but they could not be seen in the dark. It had been announced that the grandstand would be lighted and scores of cars plowed their way across meadows only to find that they had been fooled by the lights of a squadron of campers.

Might Have Waked the Sleepers.—The homecoming on the Long Island Railroad certainly tried men's souls. The time from the grandstand to East Thirty-fourth street ferry varied from 2 1-2 to 3 hours. A large portion of the passengers had made a night of it and were asleep. A wag suggested that the trains were run slow so as not to wake the sleepers.

Harvest for Fakers.—The souvenir fakers did a rushing business. A majority of the cars returned to town with little flags bearing a Vanderbilt Cup or an automobile with "Vanderbilt Cup" inscription. In the returning trains were hundreds of papas who had bought them to take home to the kiddies.

Wagons as Grandstands.—Farmers were out by scores in their big truck wagons, which they converted into grandstands, selling the seats. The wagon drivers, by the way, did not all leave their lanterns hang under the running gear as usual, but many of them waved them in warning to avoid collision.

Feared a Big Wind.—The blackboards were a bit small, but the commission feared should a strong wind sweep across Hempstead Plain on the day of the race it would demolish larger expanses of boards. At the Grand Prix a skeleton score board was used, the numbers being hung on hooks.

Had Not the Soldiers Been Late.—If the soldiers had arrived at the parkway an hour or two earlier than half-past five o'clock, they might perhaps have headed off the vanguard of the fence-climbers and prevented the crowd from precmpting the homestretch.

Avoided Garden City Hotel.—While the Garden City Hotel was crowded it was not packed to the porches as at previous cup races. Hundreds had no hope of securing a bed or a cot and had camped out all night without making the attempt.

"Greatest Ever," Says Reeves.—"It was the greatest Vanderbilt race ever run," said Alfred Reeves, general manager of the A. M. C. M. A. "I didn't think that such a bunch of comparatively old cars were good for such a performance."

Two Notable Bostonians.—Charles J. Glidden, of touring and airship fame, and Henry L. Bowden, who made the world's mile record at Ormond with his *Flying Dutchman*, were among the notable Bostonians at the race.

"Van" Toured to the Race.—N. H. Van Sicklen, former chairman of the A. A. A. Technical Board, saw the race. He had driven to the course with his wife from Chicago in his Apperson Jackrabbit.

Lingerie on View.—Women took advantage of the darkness to scale the parkway fence. Occasionally headlights happened to be turned in their direction, adding to the gaiety.

Seventy Miles an Hour Easy.—"Lighter cars with shorter wheelbase could easily make 70 miles an hour over this course," remarked Foxhall Keene after he had retired from the race.

STRANG WILL DRIVE AT NEW ORLEANS.

NEW ORLEANS, Oct. 24.—Louisiana automobile enthusiasts are making great preparations for two days' racing carnival scheduled for November 7 and 8 at the Fair grounds. All the local dealers are entering into the plans of the promoters in a way which speaks much for the success of the meeting and through their efforts many of the factories are preparing to come to the aid of their agents with machines and drivers. Strang has signified that he will be on hand with his Vanderbilt entry and a stock car in order that he may enter not only the special events, but those for stock cars as well.

The Winning Locomobile Making a Spectacular Crossing of the Westbury Bridge.

This is an authentic and copyrighted photograph taken by R. W. Tebbs, of Brooklyn. Note the fact that all four wheels are off the ground, though the left rear wheel appears to be resting on something, that something really being the branches of a tree which happen to intrude themselves into the view. The photographer exhibits the negative to prove that the camera told the truth.

THE LEGITIMATE ZONE OF THE CHAIN.

Editor THE AUTOMOBILE:

We are surprised at the statements in your editorial in the issue of October 8, 1908, wherein you undertake, at one swoop, to eliminate the chain-driven car. If your journal is entirely a general magazine for the public, and reflecting only the public ideas of design, you have done well by representing only a portion of the public who are interested in automobiles. If your journal is a trade paper, as you claim, you have then made the mistake of making statements which are not borne out by facts, i.e., that shaft drive is now universal, or so nearly so that the statement could apply, thereby antagonizing the interests and convictions of a very large number of substantial manufacturers of chain-driven cars.

As evidence that the shaft drive is not universal, I have selected 127 manufacturers of automobiles who are really producing cars in reasonable quantity. Of these 127 manufacturers

59 make shaft drive only,
19 make both shaft and chain drive,
49 make chain drive only;

12 of the 49 make double chain drive, and 3 of the 19, makers of both shaft and chain drive—use double chains. These three are Apperson Brothers, Locomobile Company and E. R. Thomas Motor Company. The last two are the only double chain drive makers who have yielded to the public's (?) demand for a light gear-driven car. They still supply the chain drive also. These two are the only important makers who have made the change recently, while to read your editorial, one would think the whole tide had turned to shaft drive.

Your editorial is criticized by the makers of chain-driven cars as extravagant, misleading, and not borne out by facts. We feel that your position toward the trade and the public should be fair and unbiased, and if you find that it is necessary to discourage the chain drive proposition, stick to facts or arguments.

The real fact is that the number of new chain drive cars made in 1908 exceeded any previous year—and the 1909 production will in numbers almost double those made in 1908. The number of makers of chain drive cars who have changed to gear drive for 1908 is smaller than in any previous year, and the objection to chain drive by the public, and especially by the engineer, is less than ever.

The public has no doubt been the final court in the decision against chain drive—formerly they had good cause. The size of chain and sprockets, construction of the car, and the inordinate conditions under which chains were operated, caused many chain troubles, and the public naturally condemned chain transmission. The only remedy with numerous makers seemed to be that they at once change to shaft drive. In the meantime, a few makers set about to better the conditions, with the result that where the conditions are harmonious with scientific principles and laws, the chain is far more efficient, less expensive to maintain, and with less cost for upkeep of tires than is possible with the shaft drive. The public, the engineer, and the designer will appreciate this more and more, and, by natural evolution, chain drive will continue to grow in general favor.

We are pleased at the good, healthy growth of the business. We do complain of the wholesale manner in which you undertake to eliminate the chain drive, and thereby antagonize the many high class manufacturers, and the thousands of individuals, whose opinion and preference is, and will continue to be, in favor of chain drive.

DIAMOND CHAIN & MFG. CO.,
Indianapolis, Ind. L. M. Wainwright, Pres.

Your letter constitutes a fine "brief" in favor of chains. The editorial you comment upon is not, in view of the previous discussions, a stricture on side chain drives for powerful automobiles. What we said was: "It is quite probable, however, that the shaft will, sooner or later, displace the single chains, now employed on some light cars." Otherwise we reflected what can only be construed as the positive trend, *i. e.*, the light touring cars and the runabout types are adequately provided for by way of the shaft drive, which provision was seriously questioned by many, *in the past*.

This is not to say chains are not capable when it comes to light cars; indeed, it is wholly unnecessary to point out that chains are used in the cars of great power, because the chains are of undoubted ability; whereas, the shaft drive has not, as yet, been proven as equal to the occasion.

In view of these facts, we properly refrain from giving space to well understood facts and confine our reflections to the matters long under serious discussion, but now quite clear, and we repeat, the shaft drive is entitled to respect and confidence, within the zones of its common application, which is no reflection on the chain and its proven ability. The public will, of course, decide in the long run the extent of the respective applications. We will record the facts and reflect the trend.

BUSY TIMES PREVAIL IN TIRETOWN.

AKRON, O., Oct. 25.—The extensions that the Akron rubber companies engaged in the manufacture of tires are making this year and preparing to make this coming year are little short of marvelous in their magnitude. Announcement has already been made of the two big buildings to be erected by the B. F. Goodrich Company as additions to its local plant besides the branch in New York City to cost over a million dollars.

One of the most important recent announcements of proposed extensions was made this week by the Firestone Tire & Rubber Company, which announces the purchase of the plant of the Globe Foundry & Machine Company, which adjoins the rubber company on the north. Plans will be soon prepared for the erection of an immense factory on the site of the new property. Secretary S. G. Carkhuff is authority for the statement that the new building will be put up next spring, and it will exceed the addition now under construction, which is 125 feet long, 50 feet wide and four stories high. The property that has been purchased by the company consists of five lots containing several buildings. The extension is due to the growth in the tire business.

The Firestone additions make ten new factory buildings that are to be constructed by local rubber companies for the extension of their business, announcement of which has been made within the last few months.

The first definite statement was made this week by the Diamond Rubber Company as to what additions it will make since the city council has vacated an important street for the benefit of the company. Owing to the increased demands for tires, the Diamond company will make additions in order to practically double its tire output. Two large buildings will be constructed on new land that has been purchased. The first one, to be erected at once, will be 300 feet long, 100 feet wide and one story high. This is to be completed by the end of the year. Following it the company will erect a five-story building of the same ground dimensions as the one-story building. An overhead bridge will connect the present plant and the new one.

The B. F. Goodrich Company is establishing four new branch houses in addition to the 14 now in existence. The new branches are to be in Kansas City, Atlanta, Minneapolis and Pittsburg. At present tires alone will be sold at these branches, but in future all of the company's products will be distributed.

The Diamond Rubber Company at its annual election this week chose the following directors: C. A. Lake, Chicago; O. C. Barber, F. A. Hardy, A. H. Marks, W. B. Miller and O. S. Hart, Akron, Mr. Hart succeeding E. K. Hardy, who resigned. The directors chose the old officers again as follows: President, F. A. Hardy; vice-president, A. H. Marks; secretary, W. B. Miller; treasurer, A. H. Noah.

Having six of the nine American cars in the Vanderbit race Saturday equipped by Diamond tires, the Diamond Rubber company was well represented at the contest. Those present were A. H. Marks, W. B. Miller, J. A. Braden, J. D. Tew and C. B. Myers, the last named being the company's best tire expert.

H. S. Firestone, president of the Firestone Tire & Rubber Company, is at present in the West visiting the company's agencies and investigating business conditions as it pertains to the tire trade. He will visit the leading cities on both sides of the Rockies, and will be home in two weeks.

FAIR QUAKERESSES HAVE A MANLESS RUN.

PHILADELPHIA, Oct. 26.—The annual run of the Ladies' Quaker City Motor Club took place last Wednesday over a course laid out from this city to Lakewood, N. J., and return, a distance of approximately 130 miles. A score of this city's fair automobile enthusiasts took part in the run, which was led by President Mrs. Joseph J. Martin in her big Mercedes. Mrs. G. A. Reach drove her six-cylinder Stevens-Duryea, Mrs. Herbert B. Knox drove her Royal Tourist, and Mrs. S. E. Bailey drove a Pullman.

AMERICAN CARS IN SOUTH AMERICA.

After a trip of close to six months, during which time he has been traveling through South America in the interests of the Dayton Motor Car Company, Dayton, O., manufacturers of the Stoddard-Dayton cars, Sigmund Kraus has just returned from Buenos Aires, via Lisbon and Paris, and reports an excellent market below the equator for American built automobiles. Prior to making his South American trip, Mr. Kraus showed the paces of the Stoddard-Dayton to the auto enthusiasts of Habana, where the car met an unusually favorable reception. After returning from Cuba he sailed from New York on May 1, stopping at Bahia, Rio de Janiero, Montevideo and Buenos Aires, agencies for the car being established in the three last-named cities.

"South Americans are strongly prejudiced in favor of European built cars," said Mr. Kraus when seen prior to departing for the factory at Dayton, "and with good reason, for the first American cars sent down there were certainly not of the kind to build a reputation on—at least not a good reputation—and they only served to give American automobiles a black eye. But the fine construction, graceful lines, and, above all, the silent running and snappy action of the Stoddard-Dayton impressed them very favorably, so that I not only had no difficulty in disposing of the twelve sample cars that I took along with me, but took orders for several more besides. Business conditions in South America are not at their best by any means just now, and the credit system current there is another drawback to the introduction of a new car, but for all that there is a good market for the medium priced car of American make. The same thing is true of Europe, and even of France itself, in my opinion."

After spending a short time at the factory Mr. Kraus will make a trip through Mexico in the interests of the Stoddard-Dayton, establishing agencies in the principal centers, and will later cover Europe in the same manner.

POPE REORGANIZATION NEARLY COMPLETED.

HARTFORD, CONN., Oct. 26.—According to the statement given out by A. L. Pope, one of the receivers of the Pope Manufacturing Company, the plan of reorganization of the company is now but a matter of a short time until the matter can be put through the various courts. The plan of reorganization includes the deposit of first and second preferred stock and the issue of $800,000 of notes. About 98 per cent. of the first preferred stock and approximately 90 per cent. of the second preferred stock has been deposited with the reorganization committee. Of the notes needed a large part have already been subscribed by the stockholders, and if any remain unsubscribed this week underwriters will meet the situation at once. The total debts of the company were about $1,700,000, of which 75 per cent. has been paid out of the profits of the past year and by the sale of various properties not used by the company. The profits of the Hartford and Westfield factories during the past year amount to about $400,000.

BOSTON SHOW APPLICATIONS OPEN.

BOSTON, Oct. 26.—Application blanks for space in the Seventh Annual Boston Automobile Show, to be held in Mechanics Building, March 6-13, 1909, have just been issued from the office of Manager Campbell. For the coming show there will be available 105,000 square feet of space divided among seven departments, with nearly 600 spaces. As in the past the management of the show will take care of the decorations and the furnishings of all spaces, the cost of the space including these things as well as the rental. The cost of signs is also included and these will be uniform in character. The prices of automobile show spaces in the pleasure car department range from $750 to $100 each; in the other departments the space is to be sold at a fixed price per square foot. Already Manager Campbell has a large number of applications on file, and the first allotment of space will take place the first of next month.

NEW ISSUE OF AUTOMOBILE TRADE DIRECTORY.

As the result of several years' constant application, the third quarterly edition of The Automobile Trade Directory for the present year, which has just been issued under date of October, 1908, comes as near to being a complete index of the automobile industry and its legion of allied industries as it is possible to compile. The object all along has been to make The Automobile Trade Directory a valuable aid to the purchasing agent, the engineer and the factory superintendent, and, in furtherance of this, a new department has been incorporated, giving classified lists of manufacturers of machine tools and other shop equipment suitable for automobile work. This has been done at the suggestion of a number of engineers and buyers, and, as the section devoted to it comprises no less than 72 pages, its value may readily be appreciated.

The main portion of The Automobile Trade Directory is devoted to lists of manufacturers of every part, accessory and material that enters into the manufacture of an automobile, and, as an illustration of its completeness, the fact may be cited that its range comprises everything from a lamp wick to a complete car, and the information is not only put in the most accessible and concise form, but by a system of cross references, under which both the trade name of an article as well as its maker, is listed, it is easy to locate practically any manufacturer supplying the automobile trade. The entire list has been completely revised right up to the date of issue. In addition to this information, it also contains a great deal of engineering data that is of great value to both the purchasing agent and the engineer, and the presence of which in The Automobile Trade Directory makes reference to other works unnecessary.

NEWS OF THE PALACE SHOW.

The National Retail Automobile Dealers' Association has selected the Ninth International Automobile Show in Grand Central Palace as its headquarters in New York during exhibition week, which opens New Year's Eve and runs until January 7th. The Association is made up of the dealers and agents for leading American cars. Following this decision, the A. M. C. M. A. management of the Palace affair volunteered to provide accommodations for all who attend. The president of the Association is C. F. Jensen, Joliet, Ill., while J. A. Crum, secretary, is located at Oshkosh, Wis. Mr. Crum will have personal charge of the headquarters at the Palace.

Associated with L. M. Bradley, manager of the publicity department of the American Motor Car Manufacturers' Association, will be Charles E. Duryea, one of the best known mechanical engineers in this country.

Rushmore Searchlights for the British War Office.

The British War Office recently had a touring car fitted with a powerful electric searchlight by the London branch of the Rushmore Dynamo Works. The lamp contains a standard 14-inch projector, and, as shown in the photograph, is mounted at a considerable elevation so as to command a wide radius. The car carries a five-kilowatt dynamo, which may be connected with the motor by a clutch. The combination has been found very successful in the night maneuvers of the army, and it is possible that several more of the same type may be ordered.

A Stoddard-Dayton Victory in a California Track Event.

A Good Advertiser.—That A. W. Harris, of the Harris Oil Company, of Providence, R. I., is a believer in liberal advertising was shown by the Motor Parkway Sweepstakes program in which he purchased the entire advertising space. Mr. Harris happened to be the first man seen by the advertising man for the printing company, and he immediately bought all the available space. The fact that Harris oil was so much in evidence, not only on the competing cars, but in the official program, was the subject of many remarks by the spectators.

Testimonials for the Locomobile Drivers.—Recognizing the personal element in any race, as well as the quality of the tires, the Firestone Tire & Rubber Company has presented to Robertson and Florida, the drivers of the two Locomobiles in the Philadelphia race on October 10, with souvenir cups, and the mechanics, Ethridge and Connelly, medals, to show the appreciation of the company of the way in which they utilized Firestone tires during the race.

Tour of the Brush Runabouts.—The Brush Runabout Company, of Detroit, is about to put out a small booklet describing the various experiences of the five cars sent out from Detroit in August for Boston, Washington, Denver, Milwaukee, and Minneapolis. The book will be well illustrated with views taken in the different sections passed through by the five cars, showing the widely varied conditions met with.

IN AND ABOUT THE AGENCIES.

Olds, Pittsburg Branch.—The Olds Motor Works, of Lansing, Mich., has established a factory branch in Pittsburg under the management of J. V. Hall, who was formerly Oldsmobile salesman for the State of Ohio. Commodious headquarters have been secured at No. 5922 Baum street. It is planned to make Pittsburg the distributing point for all Olds cars sold in western Pennsylvania, the State of West Virginia and all the northwestern portion of the State of Maryland. This includes some thirty sub-agencies, who heretofore were handled through dealers. The agents will now handle the Oldsmobile line as a direct agency proposition.

Stepney Spare Wheels, Chicago.—The retail store of the Stepney Spare Wheel Company, 236 Michigan avenue, has been closed, and the company has established a branch house with the Excelsior Supply Company, 233-237 Randolph street, for the control of the Middle West. The other branches are as follows: Eastern territory, 1773 Broadway, New York City; Western territory, Auto Spare Wheel Company, Kansas City, Mo. Sales Manager George S. Morrow will divide his time between the three branches, and look after the company's exhibits at the coming shows.

Hyatt Roller Bearings, Detroit.—The Hyatt Roller Bearing Company, of Newark, N. J., will open an office in the Majestic building, that city, at which Peter S. Strecnstrup, the general sales manager, will make his headquarters after November 1.

Pittsburg Auto Tire Repair Company, Pittsburg.—The quarters formerly occupied by the Fisk Rubber Company, at the corner of Baum and Beatty streets, have been leased by this concern, which will take possession November 1.

Apperson, Kansas City, Mo.—The Pioneer Motor Car Company, 3028 Gillham road, with Charles Dinklage, formerly of the Kaw Valley Auto Company as manager, will handle the Apperson line for the coming season.

Empire Tires, Pittsburg, Pa.—The Consumers' Auto Supply Company, Seventh avenue and Smithfield street, has been appointed agent for Pittsburg and vicinity by the Empire Automobile Company, of Trenton, N. J.

White and Pierce, Pensacola, Fla.—A company has been formed by W. A. Gahlenbeck, of Pensacola, and E. E. Wager, of the Southern Automobile Company of Mobile, to handle the Pierce and White cars for 1909.

White, Chattanooga, Tenn.—The newly formed Crescent Automobile Company, of Chattanooga, Tenn., has taken the agency for the White steamer and opened up a garage and salesroom at 18 Williams street.

Franklin, Kansas City, Mo.—The Franklin interests in Kansas City will be looked after by Lewis A. Robertson, who has incorporated a selling company and is making full preparations for a busy season.

Stoddard-Dayton, Scranton, Pa.—Conrad Brothers, of Scranton, Pa., have closed a contract with the Dayton Motor Car Company to represent the Stoddard-Dayton cars in that territory.

Remy Magneto, New York City.—The Remy Electric Company, of Anderson, Ind., has opened a New York office in the Thoroughfare building, Broadway and Fifty-seventh street.

PERSONAL TRADE MENTION.

Zenas Carter has been appointed manager of the publicity bureau recently established by the Pettingell-Andrews Company, Pearl street and Atlantic avenue, Boston. Mr. Carter has had 10 years' experience in the printing and advertising fields, and will have entire charge of the company's automobile and electric specialties departments. A new 16-page catalogue with an exceptionally artistic cover attests the energy of Mr. Carter in getting quickly to business. The new book is called "Ignition," and lists the "J. & B." coils, vibrators, switches, spark plugs, and other specialties for which the company is agent.

Sidney B. Bowman, of the Sidney B. Bowman Company, New York City, accompanied by his superintendent, John F. Merk, sailed Tuesday on the *Cecile* for his annual trip to the Clement-Bayard factory, Paris. Just before sailing a committee representing the seventy-five employees waited upon Mr. Bowman, wished him a pleasant journey and safe return, and accompanied the compliments with a floral horseshoe. Mr. Bowman intends to return in time for the Savannah race, in which he has two Clement-Bayards entered.

Charles H. Bauer has resigned from the Studebaker Company to assume the sales management of the Austin Automobile Company, of Grand Rapids, Mich., which concern's output of six-cylinder cars will be greatly increased for the coming year. Mr. Bauer is well known to the automobile trade, having been connected with the Electric Vehicle Company, Hartford, Conn., previous to his Studebaker connection.

J. J. Mann, managing director of the Societe Anonyme des Automobiles Delaunay-Belleville, of Paris, has just arrived in this country for the purpose of making American arrangements for his company. Mr. Mann formerly had Hotchkiss connections and is well known on this side.

Charles C. Craig, sales manager of the Model Automobile Company, Peru, Ind., maker of the Great Western cars, is on an Eastern trip in the interest of the company's 1909 product, which will be equipped with four-cylinder motors.

Claude H. Pratt, who has been the Fisk representative for Ohio and West Virginia for some time, is now manager of the Cleveland branch, succeeding C. H. Gage, who has accepted a position at the factory.

IMPORTANT CLEVELAND DEAL.

CLEVELAND, Oct. 26.—The local field is about to see one of the greatest changes of recent years, for, following the announcement of the Studebaker-Garford combine, comes word that the Metropolitan Motor Car Company, local Pierce and Knox agents, has been absorbed by the Studebaker-Garford combine. This change, which has been under consideration for some time, involves the taking over of the garage of the Metropolitan Motor Car Company on East Nineteenth street, near Euclid avenue, by the new combination under the management of A. R. Davis, secretary of the Garford company. The entire garage will be changed to meet the new conditions.

The new concern will also sell the E-M-F, as well as the Studebaker electric (both pleasure and commercial vehicles). In addition the entire garage and repair shop service of the Metropolitan will be continued, so that there will be four departments in the new concern. A. E. Foss, well known to the trade, will continue as superintendent of the garage.

In addition to his local business, Mr. Davis will also have a great deal of State territory to cover, and he has selected Joseph D. Porter, formerly New York manager of the Wayne, to look after the outside interests for him. Porter will have charge of all outside territory for the Studebaker-Garford, Studebaker Electric, and E-M-F, working under the general direction of Mr. Davis.

L. XIX NEW YORK—THURSDAY, NOVEMBER 5, 1908—CHICAGO No. 19

THE AUTOMOBILE

Quakerville's "Legal Speed Limit Run"

PHILADELPHIA, Nov. 2.—That Eastern automobile classic, the Brazier Cup contest, that in antiquity, if not in importance, exceeds even the Venderbilt Cup race, was decided on Saturday last over a 65-mile course which gave the contestants liberal variety of road conditions and an opportunity of exhibiting judgment as to pace. The field was a small one—only nine starters—but the affair was carried out with a minuteness of detail that reflected great credit on the officials. Gustavus B. Fletcher, in a Packard runabout, who won the 1905 contest, repeated on Saturday and was adjudged the winner, his penalties totaling the lowest—17 min. 30 sec.

The contest committee of the Automobile Club of Philadelphia called the affair a "legal speed limit run," and when it is remembered that the route lay through two score villages, towns, boroughs, townships, with a bewildering variety of speed ordinances to collect and adhere to, it is not to be wondered at that a perfect score was a *rara avis*. To assist the contestants, the committee allowed them not only to carry watches and speedometers, but supplied each of them with a speed chart as a partial guide. The chart divided the route into thirteen sections, in each of which the average legal speed limit was set forth. Open country was fixed of a 20-mile speed, and but two short sections of the thirteen allowed of that limit. It was amusing to see each contestant and his assistant, watches and cards in hand, keeping tabs on mileage and speed in an effort to land the cup. That the winner was nearly 18 minutes shy of the actual figures as decided upon by the committee, is an indication that judgment of speed among automobilists generally is not a common commodity.

In arriving at their decisions, the judges used the times recorded by watches at three blind controls, which must have been well secreted, for the press bunch in Wayne Davis' big Matheson could see nary a hide or hair of them, although they kept a sharp lookout. Cars that arrived at these secret controls and at the finish ahead of or behind their allotted times were penalized in minutes and seconds, and the sum total of these derelictions furnished the final scores upon which the decisions were arrived at. A good mathematician was as useful as a judge of speed.

Confetti was scattered at each turn and where speed limits changed, but in many instances the 35-mile northwest gale, which prevailed throughout, blew most of the markers into the next county, and it required veritable Sherlock Holmes work to decry among the dead leaves at the side of the road a telltale bit of the paper which rude Boreas had somehow overlooked. Many strayed from the route in consequence, which probably will ac-

count for any delays in arriving at the controls and finish. Most of the penalties, however, were imposed for early arrival, for whenever a contestant went astray he immediately "beat it" and usually more than made up the delay. An idea of the moderateness of the pace may be had from the fact that the big press car, which started absolutely last and stopped several times en route to allow the benumbed pressmen to thaw out their frozen bearings, reached the head of the line at the 40-mile point. It is to be feared, however, that Pilot Davis, who was at the wheel, and who was untrammeled by schedules, may have ignored in one or two instances the speed ordinances of the villages and townships, despite the fact that almost the entire route lay through the "trap country." Nothing could be seen from the press car.

None but members of the Automobile Club of Philadelphia were eligible to compete, and owners were drivers in every instance. The following summary will explain matters:

Car.	Owner & Driver.	Start.	Finish.	Penalties.
Packard	G. B. Fletcher	9:10 A.M.	1:02:00 P.M.	17.30
Winton	H. P. Bailey	9:18 A.M.	1:09:00 P.M.	18.30
Pennsylvania	C. Y. Abbott	9:14 A.M.	1:08:30 P.M.	22.00
Elmore	F. Hardart, Jr.	9:12 A.M.	1:06:00 P.M.	22.00
Buick	Horace Allen	9:02 A.M.	1:03:30 P.M.	32.00
Packard	E. L. Miller	9:00 A.M.	1:02:20 P.M.	52.00
Pope-Hartford	John D. Avil	9:09 A.M.	1:34:30 P.M.	71.30
Franklin	John B. Curtis	9:08 A.M.	Did not finish.	
Autocar	W. S. Harding	9:06 A.M.	Did not finish.	

This was the sixth contest for the cup, A. H. Chadbourne having won the first, Dec. 5, 1903; C. H. Gillette the second, Oct. 1, 1904; Gustavus B. Fletcher the third, Oct. 7, 1905; George L. Mayer the fourth, Oct. 30, 1906; and Alan Wood, 3d, the fifth, November 2, 1907.

FOREIGN DRIVERS ARRIVING FOR THE GRAND PRIZE

AMERICA seems now to be assured of representation in the Grand Prize race at Savannah on Thanksgiving Day, at least equal to that of Germany and France. At practically the eleventh hour three entries were made that will fill the gap caused by that number of withdrawals and give to the United States a team of five cars. The nomination of the Chadwick that distinguished itself during the middle stages of the Vanderbilt Cup race, with Willie Haupt for its driver, was made almost immediately following the Long Island contest. On Monday, the day set for the closing of the Savannah entries, a Simplex and a National were added to the list.

The Simplex is nominated by Charles A. Singer. It is the same car that won the Brighton Beach 24-hour race on October 2-3, scoring 1,177 miles, a new record. Joseph M. Seymour, who drove a Simplex in the Briarcliff race, is named as its pilot.

The National that has been nominated is a six-cylinder car of 60-horsepower. The National holds the world's 24-hour record for continuous running, having made 1,095 miles on the dirt track at Indianapolis, November 17, 1905. Since then every 24-hour race has had stoppages for "repairing" the track.

The announcement of the withdrawal of the Matheson and Locomotive cars has been made and an official statement issued that the B.L.M. would not start.

"We entered the Vanderbilt race without adequate preparation," said C. W. Matheson, president of the Matheson Automobile Company, "and have no intention of repeating our mistake at Savannah. The factory is too busy getting out our 1909 cars to be able to tinker further with our racing machine. It will, however, be thoroughly prepared and tuned up next Spring and will be a contender in all the big events of the 1909 season."

On Monday, the date set for the closing of the Grand Prize entries, four countries had made entry of teams—America, Germany, France and Italy. The last-named had nominated six cars, the others five each. The A. C. A. contest committee had no further entries in anticipation. The list was as follows:

FRANCE.	
Clement-Bayard	Lucien Hautvest
Clement-Bayard	Victor Rigal
Lorraine-Dietrich	Arthur Duray
Renault	Francois Szisz
Renault	Lewis Strang
ITALY.	
Fiat	Louis Wagner
Fiat	Felice Nazarro
Fiat	Ralph de Palma
Itala	Henri Fournier
Itala	Alexander Cagno
Itala	Giovanni Piacenza
GERMANY.	
Benz	Victor Hemery
Benz	Rene Hanriot
Benz	Fritz Erle
Mercedes	Poegge
Mercedes	Salzer
AMERICA.	
Acme	Cyrus Patschke
Lozier	Harry Michener
Simplex	J. M. Seymour
National	Emile Stricker
Chadwick	Willie Houpt

Up to Saturday seven of the European drivers had arrived. Alexander Cagno and Giovanni Piacenza, who will drive Italas, came in on the *Koenigen Louise* on Thursday. *La Lorraine*, which arrived on Saturday, brought Felice Nazarro and Louis Wagner, of the Fiat; Lucien Hautvest and François Szisz, of the Clement-Bayard, and Arthur Duray, of the Lorraine-Dietrich team. It is expected that before the week closes all of these drivers will be installed at their training quarters on the Savannah course. Of the seven arrivals, four have been winners of classic international races.

An invitation was extended to William K. Vanderbilt, Jr., who has been referee at all the international races in this country, by the A. C. A. contest committee to serve in the same capacity at Savannah. Mr. Vanderbilt declined, pleading poor health and business as an excuse.

Paul LaCroix and Sidney B. Bowman, representing respectively the Renault and Clement-Bayard in this country, sailed for Europe last week, but will return in time for the Savannah races.

The date set for the closing of nominations for the light car race, which will be run on Wednesday, November 25, was Monday. That day 19 entries had been made as follows:

Car.	Cyl.	Bore. (Inches)	Stroke. (Inches)	Weight.	Driver.
Maxwell	2	4	4	1,100	C. W. Kelsey
Maxwell	2	4 1-2	4	1,150	
Maxwell	2	5	5	1,700	
Maxwell	2	5	5	1,700	
American Aristocrat (2-cycle)	3	3.55	3.5	1,200	K. R. Manville
Cameron (Air-cooled)	4	3 3-4	4 1-2	950	F. E. Cameron
Chalmers-Detroit	4	3 3-4	4 1-2	1,600	Bergdoll
Chalmers-Detroit	4	3 3-4	4 1-2	1,600	Burne
Oldsmobile	4	3 3-4	3 3-4	1,700	
Oldsmobile	4	3 3-4	3 3-4	1,700	
Oldsmobile	4	3 3-4	3 3-4	1,700	
Buick	4	3 3-4	3 3-4	1,550	Easter
Buick	4	3 3-4	3 3-4	1,550	Jeffers
Buick	4	3 3-4	3 3-4	1,550	Hearne
Buick	4	3 3-4	3 3-4	1,550	Burman
Buick	4	3 3-4	3 3-4	1,550	Hilliard
Lancia	4	3.74	4	1,100	Lytle
Isotta Fraschini	4	2.44	3.50	1,500	Juhaz
S. P. O.	4	3.70	3.70	....	Robertson
Gregoire	4	3 2-10	5 2-10	....	

Among the last cars to arrive for the light car race will be the Lancia and the S. P. O. Signor Lancia was given short notice, but cabled he would be able to get through a car in time.

In addition to the *City of Savannah*, which the Automobile Club of America has chartered outright, the club has reserved all the cabin space in the *City of Columbus*, which will also sail the Saturday before the race. The promoters of special trains on the Seaboard Air Line and the Atlantic Coast Line, which will also serve as hotels during the races, already report large reservations.

A Western Hotel Train for Savannah.

CLEVELAND, Nov. 3.—If present plans are successful, a special train will leave this city for the Savannah races. Plans are being laid to secure at least three Pullman loads, and in case this is successful baggage and dining cars will be added. The party will live in the train the entire six days of the trip. President Bonnell of the local club is in charge of the movement.

The Best Route from New York to Savannah

Ferries of This Sort Are to Be Seen Frequently Throughout the South.

MANY readers of THE AUTOMOBILE will remember the series of articles which I wrote last Winter describing my tour m New York to Savannah. It will be recalled that the route ich I covered at that time was by no means the most direct, t led eastward over the National Highway to Columbus, O., d then southward by way of Cincinnati, Lexington, Louisville, shville, Huntsville, and Chattanooga to Atlanta, and thence way of Macon and Statesboro to Savannah. My idea at that ie was not to travel by the shortest route, but by that which ered the most interesting sights and scenes. Furthermore, a tour which I made two years ago, I traveled via Philadel-ia and Gettysburg to Hagerstown, and then down the Shenan-ah Valley by way of Winchester and Staunton to Roanoke, . It recently occurred to me that, if I could map out a de-able route between Atlanta and Roanoke, I would then be e to supply my fellow tourists with complete data for touring a direct route between New York and Savannah.

Through the courtesy of Thomas A. Edison, who two years o spent several weeks in touring through the Carolinas in his o White Steamers, I obtained considerable information re-rding the roads in these two States, and, equipped with this a, I last week set out from Atlanta to drive to Roanoke and s cover the "missing link" between New York City and annah.

Georgia roads are bad—unpardonably so—except in those few nties in which the large cities are located. If I may digress a moment, I would like to point out a recent happening in t State which points toward a rapid improvement of its hways. There had grown up in rgia what is known as the nvict lease" system, whereby the victs were leased to "convict ters" at a nominal sum by the ral counties. The brokers, in , leased out the convicts to the ers of mines, brick-yards, and ber-camps, who worked the con-s "to the limit." As a result, a ll number of very influential ens and office-holders benefited tly by the system, and the con-were never sent out to work ie roads, except in three or four ties. The abuses of the "con-lease" system became so pro-ced that a vigorous campaign st it was started a few months by an influential newspaper, the nta *Georgian*. As a result of campaign, which opened the of the people of the State to iquities of the system, the gov-convened the legislature in session and the "convict lease" m was annihilated by statute.

Just a Touch of Southern Color.

Therefore, there is now nothing for the convicts to do but to work on the roads. If one county cannot use all of its own convicts on its own roads, it must lend them to any other county which applies for them. Thus it happens that an impetus has been given to the good roads movement in Georgia, the importance of which cannot be overestimated.

The good highways in quantity, however, are yet to be built, and on that drizzly October day when we set out from Atlanta we found it necessary to put the tire chains on the wheels of our White Steamer to prevent skidding off the slippery clay roads. The roads are not all of clay. There are many miles of sandy roads with deep ruts made by the farmers' wagons, all of which travel in one track. This is the time of year when the cotton crop is being marketed, with the result that we met countless teams on the road. In many instances, meeting a team meant that we had to stop and lead the horses or mules by our car, or, perhaps, wait until the driver could turn into some cross-road or "take to the tall timbers." Under such conditions, the progress of the tourist is necessarily rather slow.

Our route led by way of Lawrenceville, Winder, Jefferson, and Royston to Hartwell. Six miles beyond the latter town we crossed Brown's Ferry across the Savannah river into South Carolina. By an ingenious arrangement the current of the river operates the ferry. A cable is stretched from shore to shore, well above the level of the river, and the ferry-boat is connected by two chains to sheaves which run on the cable. By altering the relative length of the two chains, the angle of the ferry-boat to the stream is changed so that the current moves the boat in either direction which may be desired by the man in charge.

I might say here that in our entire journey from Atlanta to Roanoke, a distance of 490 miles, we had hardly one hundred yards at a time of level country. We were always going either uphill or downhill. In Georgia, the grades are sometimes very steep—dangerously so, it seems, as one guides his car down a winding road with a surface of wet clay and a deep ditch at either side. But as soon as we crossed into South Carolina we noted that the roads had been laid out much more carefully. The road surface was not much better than we found in Georgia, but the gradients were very much less.

Anderson was the first important town we passed through in South Carolina, and next we reached Greenville, a hustling city located 167 miles from Atlanta. As far as Greenville we had been cutting "cross country," in the sense that we

Odd Landmark Dividing Winston and Salem.

Convicts Smoothing the Way for a White Steamer.

Typical North Carolina Macadam Road.

In the Tobacco Market at Winston-Salem.

had not followed any line of railroad. At Greenville, we struck the main line of the Southern Railroad, and for the next 150 miles, or as far as Salisbury, N. C., we were seldom very far from the main line of this road.

All the way from Atlanta we had been in a cotton country—in fact, we had seen little else being raised. The farmers' wagons we had seen were all loaded with cotton or with cotton seed—the cotton being taken in bulk to the gins and then in bales to the towns for shipment. Starting about at Greenville, we noted a new phase of the cotton industry, namely, the cotton being made into cloth at the point of production, instead of being shipped to Fall River or to Manchester. We began to realize what is meant by the "New South." It means that in every town along the railroad great cotton mills have been built within the last few years, which compare in size with those of New England and excel them as regards up-to-date equipment. It means that vast electrical power plants have been built to utilize the great natural water powers of the State. The current is used primarily to turn the spindles in the cotton mills, but, incidentally, to bring electrical illumination into almost every home in the towns. It means that beside cotton pickers, the South needs masons and electricians and artisans of every kind, and that it is drawing the enterprising and the ambitious from every section of the country.

On we go, through the cotton fields, past the cotton mills, through Spartansburg and Gafney and Blacksburg, and then we cross the State line into North Carolina near the town of Grover. Next we pass through Bessemer City, Gastonia, and Belmont, and then—*mirabiledictu*—we are on a macadam road! For the first time since we left Atlanta, the hand of our speedometer passed the "30" mark—and keeps going. We slow down again when we meet the chain-gang, busily engaged with stone-crusher and steam-roller building more macadam, leading to the ferry, where another of those "automatic" affairs takes us across the Catawba river. We are back on the macadam, and in a jiffy we have covered eleven miles, which takes us into the center of Charlotte, 284 miles from Atlanta.

How South Carolina Came to Have Roads.

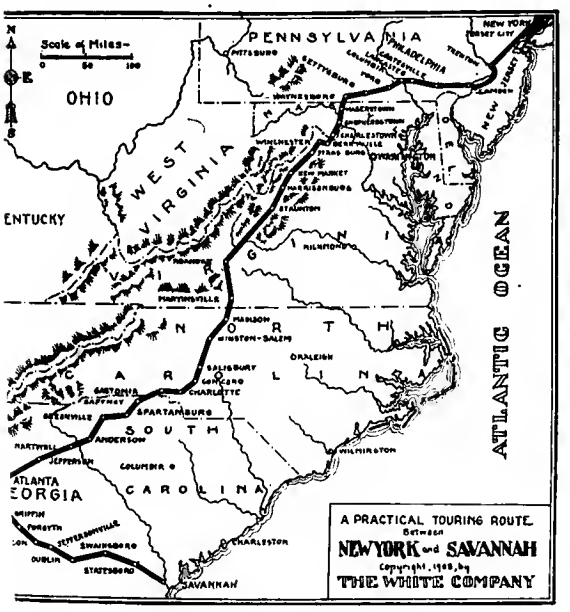
Here we took on as guide, O. L. Barringer, the original good roads man of South Carolina. He told enthusiastically of the progress of the good roads movement in the neighborhood of Charlotte. It seems that some years ago a group of enthusiasts induced the county to build a few miles of macadam road. The farmers along this stretch immediately learned, rather to their own astonishment, that their farm land was worth $10 an acre more than before. Other farmers heard about this, and they wanted a macadam road built past *their* farms. When a good roads movement progresses so that the farmers become actively interested in the cause, the automobilists need no longer worry very much about the matter. In that section of North Carolina the good roads movement is progressing famously, as we could see for ourselves. We drove from Charlotte to Salisbury, a distance of 46 miles, in a little over two hours. The road was not all of macadam, but where the steam-roller and the chain-gang had not yet done their work, we saw piles of stone at the side of the road, betokening that the good work would shortly be accomplished.

The macadam road lasted for a few miles north of Salisbury, and then we came once more to a section where the roads are as yet left to take care of themselves. Gradually we were getting out of the cotton belt and coming into the tobacco-raising country. The tobacco crop had all been harvested, and the farmers were engaged in taking it to market in their queer boat-shaped wagons, which are characteristic of that section.

Forty miles beyond Salisbury we came to the quaint town of Winston-Salem, famed as a tobacco market. Tobacco wagons by the hundreds lined the streets waiting to discharge their fragrant cargoes at the warehouses. We were told that over half a million pounds of tobacco were brought in by the farmers on the day that we passed through the town. Leaving Winston-Salem, we had a stretch of 12 miles of flawless macadam road

Kernersville, the last we were to see on our trip. From rnersville we turned due north and traversed a fair dirt ad through Oak Ridge and Stokesdale to Madison. From s point on we had rather poor going.

Thirteen miles north of Madison we crossed the State line o Virginia, and during the rest of our journey the roads were ite as bad as in the State of Georgia. We followed a single- ick railroad due north as far as Martinsville. Up to this int we had been traveling on the eastern side of the Blue Ridge ountains, which run practically parallel with the coast. The ik which now lay before us was to cross this range into the enandoah Valley. The road across the mountains would prob- ly be reasonably good in dry weather, but it was raining ien we made the trip, with the result that the going was very avy and so slippery that we could not make any progress iatever without tire chains. How many times has the thought curred to me (as it must have to many other tourists) that e makers of accessories have not kept pace with the car makers l many a long, hard tour my steam car has carried me through thout any attention other than filling the oiler, the grease ps, the water tank, and the gasoline tank. But how many ies have I stopped to fuss with one accessory or another.



ad the weather been clear, our journey across the mountains ld undoubtedly have been the scenic feature of the entire , as the foliage of the trees bore a most gorgeous autumnal ring. As it was, with the rain coming down in torrents and tire chains giving us constant trouble, it was with a great ng of relief that we brought our journey to a close in front of iotel in Roanoke.

dry weather, a good amply powered touring car should be to average about 150 miles a day for the entire journey. ainy weather, I do not believe that there are many tourists would average more than 75 miles a day south of Roanoke. uld advise those who are planning to drive from New York ivannah that they start at least two weeks prior to the time e races, so that they may have ample time if they encounter weather. I would further advise no one to start on his vithout taking at least four sets of tire chains for the rear s. As I have indicated above, progress over a wet clay is practically impossible without tire chains. As regards accommodations, one may fare very well along the route. nust, of course, not expect luxurious accommodations, but ly be quite sure that in any town of any size he need not bed hungry, and if one has been driving all day in the

For Miles Only Crop Raised Is Cotton.

open air, the question as to whether the beds are soft or not is entirely academic and not of vital importance.

The accompanying map will show what I regard as the most practical route between New York and Savannah. I have personally driven over every foot of this route, and, therefore, am able to give below exact mileages of the distances between the different towns that dot the course at intervals:

A Cotton Gin at Every Important Crossroad.

New York to Philadelphia	108
Philadelphia to Gettysburg	120
Gettysburg to Hagerstown	84
Hagerstown to Winchestsr	53
Winchester to Staunton	93
Staunton to Roanoke	88
Roanoke to Winston-Salem	121
Winston-Salem to Charlotte	85
Charlotte to Anderson	148
Anderson to Atlanta	186
Atlanta to Macon	102
Macon to Savannah	186
Total	1,274

Cotton Mills Are Numerous in "New South."

WHAT THE WORLD'S ROADS CONGRESS DEDUCTED

By W. F. BRADLEY.

PARIS, Oct. 20.—Europe's fourteen principal states possess pproximately 1,000,000 miles of ade road, estimated to be worth 5,000,000,000, and to have cost in pkeep $160,000,000. France alone as 500,000 miles of highway fit or fast traffic, exclusive of a mass f roads good for light traffic. With the advent of the railroad the ighways of Europe were robbed of heir heavy traffic; in France they vere well kept, but unused, or at ny rate unused for the purpose or which they had been created. Then, instead of means of communication they became playgrounds for the children in the neighborhood of villages, they became an extension of the farmyard, where cattle, fowls and pigs could stray about without fear of being molested.

Why Autoists Are Numerous in France.

When the automobile came into existence ten years ago the few hardy sportsmen who traveled round the country on their noisy machines had a perfect set of highways which they shared with nobody. Suddenly the authorities awoke to the fact that the automobile was skimming over these smooth military-made roads, that they were in such numbers that the surface, once perfect, was rapidly being deteriorated, and that France was in serious danger of losing her proud possession of 500,000 miles of sandpapered highways.

Minister of Public Works Barthou looked the facts squarely in the face, recognized that new systems must be adopted for new methods, and decided to call together an international congress uniting representatives of all nations, and experts from all countries. The response was an assembly of 2,500 members, speaking 29 different languages, and officially representing 28 different governments.

For ten days the twenty-five hundred have deliberated on the future of the roads, have studied the exhibition collected from all quarters of the globe, have visited and compared every example of experimental road work within forty miles of Paris, and have made copious notes.

Roads Unsuited for Fast Mechanical Traction.

It is admitted, as a starting point, that the automobile, more as a result of its speed and its numbers than because of its own special construction, is destroying the roads. To put it more equitably, the roads, as at present constructed, are unsuitable for heavy and fast mechanical traction. L. W. Page, director of the United States office of Public Roads, went into this subject in one of the 102 papers presented, declaring that the damage was done by the tractive force or shear exerted by the driving wheels of motor vehicles.

"At high speeds," he declared, "there is a considerable amount of slip, as is proved by connecting both front and rear wheels with separate speedometers. This slip undoubtedly increases the amount of finely divided material of the road surface thrown into the air. The broken stone road surface has little power to resist a shearing stress, consequently the fine material of which it is composed is carried into the air, subjected to the air currents caused by the body of the car, and subsequently to the wind."

Several other delegates who treated the same subject explained that on paved surfaces the effect of rubber tired wheels was practically nil. The case of the Avenue des Champs Elysées reserved entirely to automobiles, was given as an example of the small amount of damage, the only effect of the rubber tires being to polish the wood blocks smoother. Granite or other hard stone pavement, if laid on a solid foundation, hardly suffered at all from automobile traffic. The binder between granite blocks might be sucked out by the action of the pneumatic tires, but this could easily be remedied by the use of more suitable material. Chains and all anti-skid devices came in for criticism as road destroyers on powerful cars driven at high speeds, one English road builder going to the extent of proposing fine or imprisonment for all who used them. It was quickly pointed out, however, that under a makeshift system it was often necessary to use non-slipping devices, though they might be injurious, which would be unnecessary under scientific methods of road construction.

Robert Philipps, consulting surveyor of the Gloucester County Council, was of opinion that rubber tired vehicles did not require a very strong road, but they must have a smooth surface, the effect of pneumatic tires jumping from ridge to ridge being to file or grind the upper surface of the metal, suck out the binding material and lossen the road. Below twenty miles an hour there was little damage; above twenty miles an hour the effect was serious. Beyond what was due to speed, little damage was done by either solid rubber or pneumatic tires.

Ideal Road Varied from Point of View.

The ideal road varied according to the point of view of the expert, influenced by the conditions under which he had been trained. Smooth granite paving was frequently advocated where traffic was heavy, either for cities or for main country roads. Made brick pavings, and various types of asphalts also found adherents though asphalt was not usually recommended except where traffic was of a lighter nature. "Nothing but granite sets would withstand the constant effort of traffic," declared several of the English experts, supplementing the statement, however, with the remark that the granite must be properly laid on a foundation of cement.

"A smooth basaltic or granite macadam road is the ideal for rubber-tired automobiles," declared Robert Philipps, one of the English delegates. "For both horse and motor traffic it was necessary that the cross section should be as flat as possible, to prevent side slip; this kind of road was not at all detrimental to horse traffic, though rather difficult of drainage. All curves should have a radius sufficient to enable approaching vehicles to be seen around the curve. All roads joining at right angles should be trumpet mouthed at their junction."

The excessive crown of roads was in the opinion of M. Moissenet, chief of roads and bridges at Montauban, one of the causes of unnecessarily rapid deterioration.

In order to preserve pavements and roadways Engineer Caldagues, of the Paris roads and bridges department, insisted on the necessity for more and more proscribing the placing of gas, electric, and water mains under roadways. When a departure has to be made from this rule, the road department should reserve to itself the care of replacing the roadway against reimbursement on a suitable tariff.

Harder and better material was constantly insisted upon for macadam roadways, in order that they might be able to resist the effect of fast traffic. There should be increased cohesion by longer rolling, by the use of proper binders, and by surfacing with tar. Tar roads, which have been very extensively experimented with in France, were not received with full favor by the congress. It was only after long discussion that a non-

commital resolution was passed, in which the conference "recommended paving for a remedy against dust where traffic was heavy and intense. Crude oils and deliquescent salts were a remedy against dust, but were only ephemeral in their results. The congress believed that tar was undoubtedly a remedy against dust, that in a certain measure it protected the roads against the destructive effect of automobiles."

France is more interested in the building of tar roads than any other nation, having at the present time 1,400,000 metres of tar roads, compared with 550,000 square metres for England, and 510,000 square metres in Germany. Dr. Guglielminetti, the president of the Anti-Dust League, was of opinion that if tarring could not replace asphalt or paving on roads of very heavy traffic, it gave excellent results on roads of moderate traffic, and especially where automobile traffic was very intense. The skin of tar prevented the pneumatic tire from sucking up the binding, and for this reason prevented the grinding down of the roadway. In Paris tar surface has increased from 21,000 square metres in 1904 to 360,000 square metres in 1907.

F. G. Carpenter, of the West Riding of Yorkshire, was of opinion that nothing was so effective as the use of tarwashing. The application of tar forms a waterproof sheeting over the surface of the road protecting it from the weather and thereby lengthening its life. The best result was obtained after a new sheeting of metal had been rolled in and allowed to dry, when the tar penetrated the surface much more deeply than on application to an old or partly worn surface. A lengthening of the life of the macadam of about 20 per cent was obtained by the use of tarwashing.

Experiments with Tar-sprayed Surfaces.

A feature of the different visits to Paris and the immediate suburbs was the opportunity for examining the latest experiments of macadam roads with various kinds of tar-sprayed surfaces, and such methods of construction as Tarmac, Pitch-macadam, Aeberli and others, in which the material to be used is prepared and mixed with tar before being brought to the road under construction. As many of these processes were in an experimental stage, the congress, while recognizing that the suppression of the dust nuisance was doubtless to be found in this direction, did not pronounce definitely in favor of any one system. The future will tell.

Road signs were discussed entirely from the European standpoint, the points insisted upon being simplification and a reduction of the number of signs in use. Jacques Ballif, president of the Touring Club of France, protested against unnecessary matter on the government sign posts, asking what use it was to be told on every post that the road was a departmental or national one. The omission of such matter would tend to simplicity. The president of the Touring Club of France agreed to abandon the word signs which are at present in use in favor of a system of wordless signs as used by the Association Generale Automobile. It was decided that four signs were all that were necessary: to indicate danger points, frequent turns, railroad crossings, and dangerous cross roads. The A. G. A. signs, which were used in the last Vanderbilt Cup race are at present about twelve in number, the warning being given by a simple white diagram on a black ground, without any necessity for wording. Several thousand Touring Club of France signs have been put throughout France, and are still useful for slow traffic. For fast motor traffic they have considerably diminished in value, for it is generally impossible to read them at speed, and they are placed too near the danger spot to be effective.

A Typical Road in France, of Which There Are Many.

Roads Exhibition Attracted Attention.

Apart from the deliberative gatherings, a very extensive roads exhibition attracted much of the attention of the members of the congress and the general public. The exhibition united a vast amount of material connected with the building and maintenance of roads, and several useful comparative exhibits from city councils, road departments, etc.

The city of Paris put forth an interesting comparative exhibition of its experiments in the adoption of mechanical substitutes for horse traction in the street sweeping and watering department. The first mechanical sweeper and sprinkler was a steamer adopted in 1901, and still doing service. As its weight, however, is nearly eleven tons, its effect on roads is such that it cannot be considered a complete success. The second mechanical sweeper was operated by a two-cylinder Aster gasoline motor, which gave excellent service and is still in use. Three years ago a larger sweeper and waterer was adopted, the motive power being a two-cylinder De Dion of 15-18 horsepower, driving the vehicle at 8 to 9 miles an hour. Except that the power was found to be rather low, this was considered very satisfactory. It had been decided to take out the two-cylinder motor and substitute a four-cylinder model of the same make. A Mors watering cart was shown for use on wide avenues where traffic was fast and intense. Its four-cylinder 24-horsepower engine gave a speed of 10 miles an hour, which was sufficiently fast to avoid interfering with traffic, and its sprinklers could cover a width of 70 feet at one watering.

There were one or two cases of the conversion of horse-drawn sweepers to gasoline-driven machines, by the adoption of a front drive device, a two-cylinder gasoline engine transmitting power through longitudinal shafts and universal joints to the front road wheels. The rear portion of the machine was unaltered, the drum being revolved from chains on the road wheels, as in the old horse system. The experiment had been found more economical than the abandoning of horse material.

Also in the city of Paris exhibit were several examples of portable single-cylinder De Dion gasoline engines mounted on a suitable stand and driving a wood-block trimming machine. The outfit was naturally for use on the streets, and was used where no electric mains were laid. Where electricity was obtainable it was preferable to use an electric motor link up to the mains.

Among the private exhibits of the application of motor vehicles to road maintenance purposes were several mechanical sweepers, one of the most pleasing being fitted with a two-cylinder Renault engine carried forward and driving by propeller shaft an internal gear to the road wheels, the drum being operated by sep-

ırate shaft and single chain. This idea attracted careful examnation, and proved to be a most interesting exhibit.

Among the American delegates taking part in the congress vere: H. H. Cross, Chicago; Samuel C. Lancaster, Professor Highway Engineering, University of Washington, Seattle, Wash.; Samuel Hill, president Washington Good Roads Association; R. H. Thomson, city engineer, Seattle, Wash.; E. L. Powers, publisher *Good Roads Magazine*, New York; Harold Parker, chairman Massachusetts Highway Committee, Boston; Anstin B. Fletcher, secretary Massachusetts Highway Committee, Boston; Chandler Withington, chief engineer, Department of Finance, New York City; Arthur W. Dean, state engineer, New Hampshire; Nelson P. Lewis, New York; G. L. Clarke, Boston; William S. Hogan, New York.

Papers were presented by Ch. W. Ross, Newton, Mass.; L. W. Page, U. S. Board of Public Roads; Col. Chas. S. Bromwell, Washington; Clifford Richardson, New York City; John A. Pettigrew, Boston, and Philip W. Henry, New York City.

SECOND ROAD CONGRESS WILL BE HELD IN 1910

PARIS, Oct. 26.—The 2,250 members of the first International Road Congress have dispersed to their respective twenty-nine countries, leaving behind as a permanent record an international road office established in Paris, a mass of decisions regarding road building and maintenance for automobile traffic, and a resolution to meet again in Brussels for the second confabulation during the Belgian Exposition of 1910. At this second meeting the delegates will be the guests of the Belgian Government.

Considerable value is attached by all the members, and especially by the American delegation, to the formation of the permanent association, controlled by an international commission, and having offices in Paris. It is this association, composed of two members per nation, and having as its temporary officers those who administered the present Congress, which will be responsible for the second gathering at Brussels. Its most important work will be to collect information regarding experiments in road building, to organize and encourage chemical and mechanical experiments with tar and other road building material, and generally assist in the adaptation of highways to modern conditions of locomotion.

Conclusions of the Final Assembly.—These, after discussion in the sections, are somewhat voluminous, and are not limited in their application. Dealing with the present road the congress found better material should be used, and that greater attention should be paid to foundations. A cement bed 4 to 6 inches thick should be paid for all pavings, whether with large or small blocks. There should be a thin layer of sand between the foundation and the blocks. Experiments with tar or bituminous products incorporated into the road-making material were recommended, in order to arrive at some cheap and efficient method of carrying on this work. Paving with small stones having been reported to give excellent results as regards resistance and cheapness, it was recommended that they should be further tested with various kinds of traffic.

General Methods of Maintenance.—Complete resurfacing, in place of partial repairs, was recommended. Also the entire width of the roadway should be resurfaced at one operation wherever possible, the traffic being turned off into side roads while work was in progress. Hard and homogeneous road material only should be used, the binder should be suitable to the road, and moreover reduced to a minimum. Authority to lay water, gas, and electric mains under paved roads should only be granted in exceptional cases, and for want of any other practical solution.

Anti-Dust Crusade.—Paving and other improved surfaces were recommended as a remedy for wear and tear, as well as to remove the dust nuisance. It was considered that oiling, the use of deliquescent salts, etc., were efficient as a dust remover, but their benefit was not of long duration, and their use could only be recommended for special occasions. Planting of trees along the roadside was recommended with a view to the suppression of dust. The official decision on surface tarring was that when well carried out it was undoubtedly an efficient remedy against dust and that to a certain extent it protected the roads against the destructive action of fast vehicles. Experiments in tar-made roads were not considered to be sufficiently advanced to allow of a decision. Experiments, however, should be encouraged.

Future Roads.—That it should be well constructed of hard material, resisting and not slippery, was understood. In addition the future road should have a single track for all vehicles, with the exception of high-class avenues, and in no case should the width be less than 20 feet. Camber should be as low as possible, compatible with efficient drainage. The radii of curves should be as great as possible, and in no case less than 164 feet, while the outside should be banked slightly. Nothing should be allowed which would obstruct the view at curves; intersecting roads should be visible and very wide; grade crossings should be avoided, or if this were impossible they should be properly announced both day and night. A narrow footpath on the inside of all curves was highly recommended, with a strict law against dumping road material on it. Though multiple track roads were not recommended, except in special cases, it was believed that cycle tracks and horse paths should be laid on the side of the road. The line of the road should be clearly defined by trees.

Effect of New Modes of Locomotion on Roads.—The Congress being composed in majority of professional road-makers, with automobilists poorly represented, there was no attempt to minimize the damage done by mechanical vehicles. Fast vehicles were declared to disintegrate the road by scattering the binder, the damage being in proportion to the speed. Too harsh an application of brakes and rapid acceleration were responsible for injury, while changes of gear did damage, though in a smaller degree. Hardened metal-studded tires were condemned, smooth tires being recommended, or if really necessary, studs of soft metal. Chains, being unknown to Europe, were not discussed. Heavy commercial vehicles should have smooth rims except in special cases and on certain roads. Heavy vehicles were declared to cause injury by depressions and ruts, and to avoid this the pressure per inch of tire should be as light as possible. A maximum of 825 pounds per square inch of tire, with diameters at present in vogue, was voted for.

Road Signs.—A uniform system of marking distances for the entire country was recommended. Unnecessary matter on sign posts should be eliminated. There should be four road signs only, announcing danger spots on the road, sharp turnings, grade crossings, and dangerous cross roads.

Road Services and Mechanical Transportation.—An average speed of 11 and a maximum speed of 15½ miles an hour were recommended for all large passenger-carrying vehicles, omnibuses, etc. The weight of the driving axle should be reduced to a strict minimum and in no case should exceed four tons. Heavy commercial vehicles were given an average speed of 6 and a maximum speed of 9 miles an hour, with an axle weight of five tons, the weight per centimeter of width of tire not to exceed 150 kilos with wheels of existing diameter.

It was the opinion of the congress that light railroads should be laid outside the bed of the road; wherever it was practically possible these lines should be on special tracks leaving a width of roadway of not less than 16 feet. When trolley car tracks had to be laid in the roadway they should be at the level of the surface, without projections or depressions, and without any change of profile, either transversely or longitudinally. The roadway should be such that a width of at least 8 feet would be provided clear of the portion on which the trolley cars run.

ABOUT AUTOMOBILE SPRING SUSPENSIONS

By THOS. J. FAY, President Society of Automobile Engineers.

THE reason for the adoption of springs will best be understood if we take into account a version of the law of the application of forces. As, for illustration, if a "tup" is tripped and it falls 10 feet, provided it weighs 100 pounds, the energy of position of the tup will represent 1,000 foot pounds, and when it strikes the energy will be expended, manifesting itself in heat and other vibrations. It cannot be said that the effective force

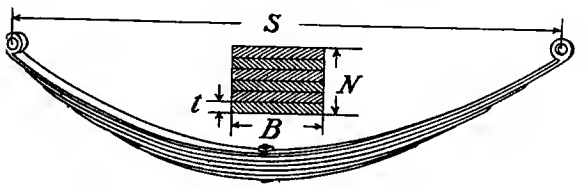


Fig. 1.—(a) Half elliptical spring, showing sections referred to in the formula.

of the blow will be as 1,000 foot pounds, because the effectiveness of the impact of the tup will depend upon the distance in which the motion is arrested. If, for instance, the motion is arrested inside of a distance of one inch after initial contact, the blow will be equal to, say, unity. But if the blow is arrested within one-half inch after initial contact, the force of the blow will be doubled. But should the anvil give but a thousandth of an inch, the force of the blow will be equivalent to *one thousand times the force as first put down.*

In this we have an illustration of the fact that it is not the weight of the body or the distance it migrates that goes to make the sum total of results; indeed, it is a question of the distance in which motion is arrested for the most part. Coming down to the automobile, it is plain to be seen that the spring suspension of a chassis frame and the superimposed body will be effective in proportion as the springs show capability, by way of arresting the motion within the distance said to be agreeable and at a periodicity of the pendulum action also said to be agreeable.

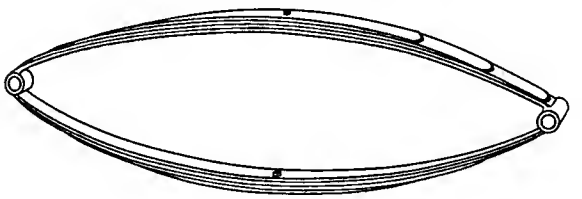

Fig. 2.—(b) Full elliptical spring.

Obviously, then, there is no standard to go by, because what one man calls agreeable, another may call something else. On the other hand, this question of what constitutes an agreeable motion can be put to some extent in dollars cost, since the anticipations of pleasurable riding will depend considerably upon how much the autoist has to pay for the pleasure. If a car is high in price, and the spring action is so terrible as not to compare favorably with the spring action in comparatively low priced cars, the unlucky autoist will consider the action disagreeable, and justly so. If, on the other hand, a car is very low priced, the purchaser thereof may be quite well satisfied with a very inferior spring performance. He may, for that matter, get all that he pays for. Under these conditions, it is difficult to appreciate what should constitute the standard spring suspension from the point of view of result, rather than the point of view of the manner of suspension.

If some types of springs do the work, affording better results than do others, it would seem as if the springs of the inferior results should be eliminated. On the other hand some types of springs work well on certain classes of cars and are valueless in other cases. This being so, it does not follow that all springs should be of the same type and all cars should be swung in the same way.

Several Types of Springs.

In relation to this matter it might be thought the types could be arranged after some fashion logical. On second thought it is to conclude there is no logic in this connection, because the several types of springs were used from time to time on all the types of cars extant. It will not seem out of place, therefore, to enumerate the types of springs largely as they appear on cars at the present time. They may be set down as follows:

(a) Half elliptical; (b) full elliptical; (c) full elliptical, one end scroll; (d) full elliptical, both ends scroll; (e) three-quarter elliptical; (f) three-quarter elliptical, one end scroll; (g) three-quarter elliptical, riveted end; (h) platform; (i) concord; (j) helical.

Each of these types of springs are shown in the illustrations, and each of them will be found in cars, unless it is a fact that the

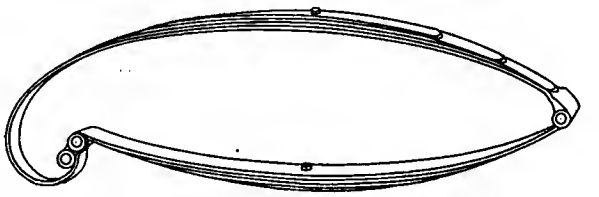

Fig. 3.—(c) Full elliptical spring—half scroll spring.

helical spring is no longer used as a direct suspension, nor has it ever been to any great extent, although it is well represented in the shock absorbers of the day.

Considering laminated plate springs, since they are all modifications, they can all be resolved through the use of a single formula by a step to step process. Such a formula, for illustration, might be as follows:

$$N = \frac{W\ S\ k}{b\ t^2}$$

in which:

S = span in inches (see Fig. 1);
b = breadth of plates in inches;
t = thickness of plates in 1-16 inch units;
W = load in tons (2,240 pounds);
N = number of plates;
k = a figure of convenience = 11 in ordinary work = 15 in the best automobile practice, and can have values between 11 and 15 as the exigencies of the service may indicate.

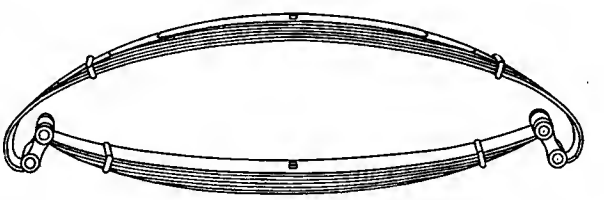

Fig. 4.—(d) Full elliptical spring—both ends scroll.

In laminated springs, ribbed cross sections are more rigid and much used in commercial vehicles, also in connection with pleasure automobiles abroad, otherwise, the plates are usually with

Fig. 5.—(e) (g) Illustrating a three-quarter elliptical spring.

round edges, but are not flat, as may be generally supposed. They are concave, and the difference of the thickness at the center is about equal to 1 B. W. G. thickness. Such plates are used in sizes as follows:

B. W. G. Nos.	Thickness in inches.
0	.34
1	.30
2	.284
3	.259
4	.238
5	.22

In automobile work there are few, if any, examples of springs, in which the thickness of plates will be found, to be thinner than No. 5, or thicker than No. 0, B. W. G.

In some cases the plates are quite rectangular in section, the edges being flat, with a slight radii at the corners. In other cases the spring leaves are ribbed, illustrations of which will be found elsewhere in this article. There is one other point, as shown in Fig. 7, which takes into account the contours of the ends of the short plates. It is believed by some spring makers, and the author has a superstition or two in relation to the same matter, that the behavior of a spring is effected by the shape or contour of the ends of the short leaves or plates. At all events, the short plates should be tapered down toward their ends, and if a supple spring is the aim of the designer it might even be well to terminate the ends of the short leaves in what is designated as the "French" contour. This contour looks very well in the finished product and possesses the advantage of more gradually bringing the shorter leaves to the support of those of greater length.

While this question of suppleness of springs, which might otherwise be termed easy riding qualities, is on the tapis, it will not be out of place to discuss some of the means by which easy riding qualities may be arrived at. In the first instance it is passing strange that the designers of some cars should expect any one to furnish springs such as would afford easy riding qualities. Take, for illustration, a limousine of the most approved artistic appearance, let us say of aluminum, and at a cost of $2,000. If the aluminum is backed by plaster of paris and a goodly showing of hardwood, by way of a framing, and if this limousine is hoisted by means of a traveling crane (suggested because of its weight) onto the chassis of a car in which the center of gravity might be high, not taking into account the effect of the body, as above described, the work the springs would have to do can scarcely be regarded as coming within the province of springs.

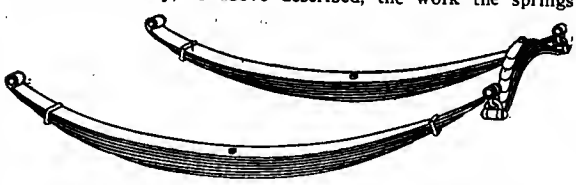

Fig. 6.—(h) Characteristic platform type of spring.

The conditions are not all included, because it is just such a body and just the car described that will have a water tank on the deck of the limousine and perhaps two or three tire cases and other paraphernalia. The "top bamper" will, therefore, mount up to figures quite beyond the "top hamper" that should obtain, even under more favorable conditions. There are no springs, either by way of types, or in the matter of design, that will afford easy riding qualities under the conditions as above illustrated. Indeed, it may be fortunate, but it is a fact, too, that there are no tires that will sustain under such conditions, and so we may say, if the spring problem is severe, the tire problem becomes impossible.

In spring making there are matters to be considered as follows: (a) the materials of which the springs should be made; (b) the facilities for use in fashioning the spring plates; (c) the facilities for use in heat-treating the spring plates; (d) the design of the springs with a view to the work to be done; (e) the manner in which the springs shall be tested. As respects the materials, enough is to say they will be given separate space hereafter. When it comes to the question of the facilities for use, in fashioning the spring plates, it will be easier to state what should not be done rather than to elaborate upon the other phase of the question. At all events, the material comes in mill lengths, and the leaves or plates have to be cut from this material, so that the first thing to consider is whether or not the texture of the material is altered by the shearing process used in cutting the spring plates from the lengths as they come from the mill. The author is of the opinion that the texture of the material is

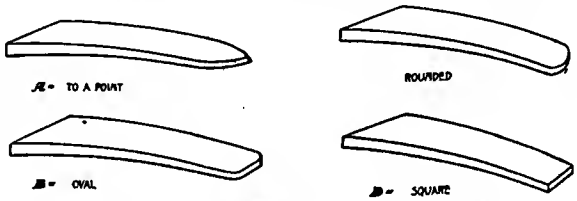

Fig. 7.—Four customary types of end trimmings.

altered for perhaps a full half inch back from the point of shear, and so it would seem that the lengths as cut from the mill lengths to make the leaves should be somewhat longer than will be required in the actual finished product.

The next question to be taken into account is that involving the thickness of the leaves in a given spring. Shall all leaves be of one thickness, or shall we have all of one thickness, excepting the main leaf, which might be of a greater thickness, or shall all the leaves be of a different thickness? The spring maker will have his say, because he sells the springs by the pound and because the more plates he has to handle per pound the more work he will have to do per dollar. If the spring maker fixes the pound price first he will then be inclined to fix upon the least possible number of leaves for the spring, thus giving him the maximum weight for the minimum cost, hence increasing his profit at a previously fixed price.

It is not intended to say that spring makers deliberately start out with the idea of skinning, but it is believed that they may beguile themselves into thinking that the less the number of plates in a given spring the less the chance of breakage for that reason alone. Of course, they know that for a given camber, the thicker the leaf the greater will be the extreme fibre strain, and with them it is a compromise as between cost and risk of breakage, due to overstepping the bounds from a fibre strain point of view. The same spring makers are justified in their course to some extent, for the reason that easy riding qualities are more nearly approached as the fibre strain in the material used more nearly approaches the elastic limit of that material. The danger lies in exceeding the point of safety, from the point of view of kinetic ability of the steel used.

(To be continued.)

WHAT IS THE BEST MOTOR TIMING?*

By LOUIS LACOIN.

VE have already sbown that it is necessary to wait until there is a degree of depression in the cylinder before open- the inlet valve, and it will be apparent that even a considerable will produce but little depression. If the cylindrical volume ¼-litre, or 750 cu. cm., and the dead space ¼-litre, or 250 cm., a displacement of 25 cu. cm., is necessary to produce in cylinder a vacuum of 0.1 atmosphere. Now, 25 cu. cm., cor- ond to 4 mm. of tbe stroke for a piston having a stroke of mm. (Cylinder 89 by 120 mm.=750 cu. cm.) It is hardly essary to state why an excessive lag should not be given the ning of the inlet valve, thougb sucb a practice would not be nded by any serious inconvenience, wbile a premature open- of the valve would permit the entrance of an excessive unt of air. Tbis consideration explains the lag of the motors ady mentioned, as well as the following: *Ours* (1), 15 de- s; *Hotchkiss* (7), 17 degrees; *Brouhot* (9), *Rochet-Schneider Cornilleau Sainte Beuve* (10), 20 degrees; *Berliet* the same *Hotchkiss*, and *Aries* (25), 18 degrees. Larrad recommends legrees.

Which Should Operate First?

his brings us to the third question, which is raised by the ing of the *Mutel* (11), *Larrad* (31) and the *Peugeot* (17) aulieu). Larrad, for example, recommends a 17-degree lag the inlet and 22 degrees for the exhaust. During the inter- ing 5 degrees, both valves are open. Is this an advantage? it can easily be seen that Larrad's theory can be sustained. ves do not operate instantaneously, he maintains. If the t valve begins to open 17 degrees beyond the dead center, egrees later, it will not be open more than a fraction of a limetre. Likewise, if the exhaust valve remains up to the nty-second degree, at the seventeenth it would not have been h nearer to closing, and the advantage is gained that the t and exhaust are both more free during their limited period, le the fact of both valves being open at the same time pro- s, with mechanically operated valves, the same effect as is ized with tbe automatic valve; the exhaust continues as long ere is any excess of pressure in the cylinder, and the aspira- commences the moment there is any depression. This point asily demonstrated as the movement of the gas in the ex- t manifold does not cease instantaneously. The inertia of gaseous mass continues to draw out the last particles of burnt despite the opening of the inlet valve, and when the exhaust s, the inlet already being open, the introduction of the fresh immediately begins. To this, it might be said that if the ning of the aspiration had any great influence on the power e motor, or upon its efficiency, this theory would not be de- le, or would at least, be well justified. But it has neither. slight initial depression scarcely bas any effect on the up- movement of piston, particularly as it is so shortly after- descending under the ordinary depression of aspiration. far as the volume introduced during the admission stroke ncerned, this may be measured by the displacement of the t between the point that the exhaust valve closes and the of closing the inlet valve in turn, assuming in both cases an equilibrium of pressure has been established between terior of the cylinder and the external air. Thus it mat- little whether the inlet valve opens before or after the ex-

If the exhaust closes, for example, when the piston has ded 1.5 mm. of its stroke, and the inlet opens but an t later, the first inrush of fresh gas will begin to fill the traveled by the piston after this 1.5 mm. of the stroke; the introduction of the gas will be somewhat retarded, but it will take place nevertheless. If the inlet valve is closed 6 mm. after the piston has reached the dead center, there will be 6 mm. of the stroke less explosive gas in the cylinder and the useful volume will be reduced by 1.5 mm. at the beginning and 6 mm. at the end, or 7.5 mm., or a deficit of .075 per cent., assuming the length of the stroke to be 100 m. This reduction of tbe volume and the consequent loss of power must be regarded as a necessary evil, for if the valves were opened and closed at the dead center, the loss would be even greater.

Should Both Valves Be Open at Once?

We are still far from having arrived at an answer to the third question and it is now opportune to revert to it. It seems that among those, such as the *Unic* (29), for example, whicb allow an interval of 24 degrees between the closing of the exbaust and the opening of the inlet, and those which, like the *Larrad*, open the inlet before closing the exhaust, there is certainly a sufficient range in which to find a mean. Without exaggerating the lag given the opening of the inlet, it seems to us that it should be slightly later than the closing of the exhaust. Imperfections in the actual timing on the motor itself will soon suffice to modify the predetermined arrangement by 4 or 5 degrees. Take a motor with a complete index on the periphery of its fly-wheel and a pointer on the crankcase corresponding to it, and order a repairman to time it exactly, and it is quite probable, that, whatever be his skill, he will not strike it by several degrees. As a mean average, it may be estimated that this error will amount to 2 degrees each way, or 4 degrees in all, and it would seem necessary from this to open the inlet 4 degrees after the closing of the exhaust. This is the regulation of the *Eudelin* (21), the exhaust having 4 degrees lag, and the inlet 8 degrees, while the *Motobloc* (5), is practically similar with 5 and 10 degrees. The *Hotchkiss* (7), allows slightly more, the exhaust having 10 degrees and the inlet 17 degrees, the *Berliet* (12) being still further apart, *i.e.*, 9 and 17 degrees, or 8 degrees apart. These figures all appear well founded.

Should we, in view of all these diverse timing arrangements attempt to distinguish what may be called the typical regulation? We hardly believe so, for, as we have already mentioned a number of times, the amount of advance or lag depends upon a number of variables in one motor and anotber; we might almost say from one cylinder to another, and those who have made much use of the manograph would probably not differ with this. A standard regulation would then be very poor for extreme cases, and if the little instrument of which we have been speaking, could improve many of the timing arrangements, it could hardly pretend to produce the maximum output or efficiency in every case, as its inventor claims. But in spite of all, we can by way of further information, give a résumé of the mean of all the angles as compared with the *Larrad*. These are:

	Mean average.	Larrad.
Lead given the exhaust valve.....	46°20′	52°
Lag in closing inlet valve.....	25°32′	17°
Advance of the ignition.....	31°15′	var.
Lag in closing exhaust valve.....	5° 8′	22°
Lag in opening inlet valve.....	12°16′	17°.

The *Brasier* (16) shows a remarkably close approach to this mean, coming within 5 degrees of it, while its r.p.m. rate is also near the average, 1,350, instead of 1,370, the length of its connecting rod being the same, 4.5 instead of 4.6. It is not to be inferred from this that many of the others are not equally good. The best are to be found in the *Motobloc* (5), *Hotchkiss* (7), *Cottin Desgoutes* (8), *Cornilleau Sainte Beuve* (10), *Mutel* (11), *Berliet* (12), *Eudelin* (21), *Farcot* (22), *Aries* (25), *Sultan* (27), *Renault* (28), and *Unic* (29). In order to be able to judge

er read before the Society of Automobile Engineers at its nd Meeting, September 18-19, 1908. Translated from the of "Omnia," by Charles B. Hayward. Continued from 07.

—The occasion for the present article was the appearance of e known as the Larrad for indicating proper timing.

of the others, it would be necessary to know more about their mechanical arrangements.

Having divided these degrees of the circumference of the circle so carefully and arranged them as indicated, is it possible to learn the time in which the motor takes to traverse the various divisions? Take for example, No. 30; it makes 1,700 r.p.m., describing in *one second,* 10,200 degrees. Each degree is thus divided into less than 0.0001 second, from which the extreme rapidity of the performance of each one of the parts of its cycle necessary to its efficient working may be realized. And still some designers refuse it a poor little thousandth of a second in which to perfect its exhaust. Those 10 degrees of retard would probably still further improve a motor already remarkable.

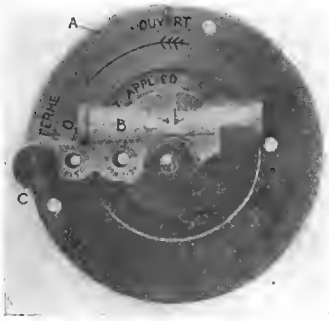

Fig. 1.—Larrad apparatus for regulating the timing of motors. A, disc, pierced with a series of holes; B, spirit level, in the case of which is a hole for each of the preceding series; C, pin to secure holes in different positions. Arrow indicates direction of rotation.

Description of the Larrad.

As shown by the illustrations, Figs. 1 and 2, this device consists of a plate *A,* mounted on a shaft *E,* integral with the piece *D,* a spirit level *B,* and the pin *C.* In the plate are three series of holes, while in the piece to which the spirit level is attached, there are but three holes, one for each series, and the pin is used to insure the registration of any two holes. To use the device, the part *D* is attached to the crankshaft, or any part that turns with it, this being arranged so as to most conveniently suit the circumstances. For example, it could be placed between the cone and the flywheel where it would be firmly held against movement. Its only conditions of mounting are that the shaft *E* must be parallel to the axis of the crankshaft, so that when turned, this shaft will describe a circle round the axis of the motor shaft, and not a cone; second, that once the plate *A* has been fixed in position, it can be revolved without coming in contact with anything. This second condition is frequently very difficult to comply with when a motor is mounted on the chassis, although the *Larrad* can be mounted on the starting crank, but the accuracy of the timing thus secured might be questionable.

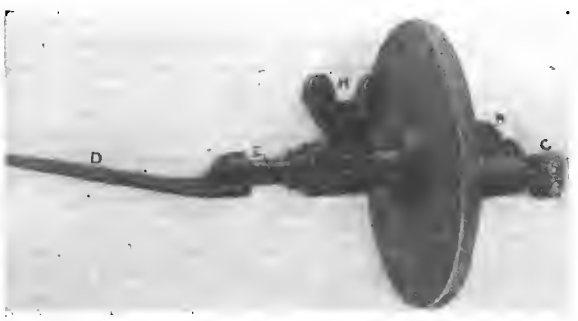

Fig. 2.—Profile view of the Larrad. A, disc; B, spirit level; C, pin; D, blade for attaching; E, shaft to be fixed parallel with the crankshaft; H, winged nut fixing disc A to shaft E.

Assuming that the piece *D* has been attached to the motor with the shaft *E* perfectly parallel with the axis of the crankshaft, the operation is commenced by registering the hole marked *exhaust,* with the hole *zero,* which corresponds to the upper dead center. The motor is then turned over, either with the crank, or by pushing on the flywheel until the piston reaches the upper dead center. The plate *A* is then turned until the spirit level shows that it is perfectly horizontal; the screw *F* is then tightened, fastening the plate *A* to the shaft *E,* and the device is then ready. See Fig. 3, No. 1. Then drawing out the pin *C,* it is inserted in the holes already mentioned, and the motor is turned until the spirit level is again horizontal. This will indicate the exact position at which the tappet should begin to raise the exhaust valve. See Fig. 3, No. 2. All the other essentials of the timing are regulated in the same manner and without removing the device from its support. In this manner, the screw is inserted in the hole *exhaust* of the socket, and the hole marked *closing,* on the plate, the motor then being turned over again until the level indicates the horizontal. The instrument simply indicates the different positions of the crankshaft corresponding to the different essentials of the timing. It must be borne in mind in using it that the cycle occupies two revolutions of the motor, and that the plate *A* to which the level *B* is attached, be so fixed that the direction of the arrow *G,* corresponds with the direction of rotation of the motor. It will be seen that the apparatus is very easily employed and that it permits of great accuracy of regulation, besides avoiding errors. It is quite probably that with frequent use by different designers, they would be able to modify the plate to suit their own motors. Unfortunately, up to the present, the inventor has only provided the single plate mentioned, claiming that the regulation he has outlined is the only perfect one.

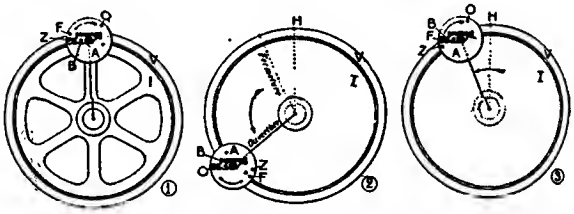

Fig. 3.—Larrad apparatus mounted between the cone and flywheel. 1, position of upper dead center; 2, position of opening of exhaust; 3, position of closing of exhaust. A, disc, pierced with holes; B, spirit level; F, closing of exhaust; H, dead center point; I, clutch cone; O, opening of exhaust; V, flywheel; Z, upper dead center point.

THINGS THAT MIGHT BE LEFT UNDONE.

Familiarity with the appearance of the motor-car on the one hand, and some amelioration of its design on the other, have done much to remove the charge of ugliness that was so often thrown at the auto in its early days. A good deal remains to be done before the eye of the artist will be satisfied, and some things should be left undone. Under the latter heading may be included the undue use of covers. One may approve the carefulness of the man who fits neat dust covers to the upholstery, though somewhat as one may smile at the prim old lady who concealed the legs of her piano in—er—garments for decency's sake, but the running of a car with the lamps swathed in chamois leather bags is surely an example of the unco' careful that is calculated to arouse unfavorable impressions. A bright lamp is doubtless a thing of beauty, but it will not be a joy forever if it is concealed under an article, which, if not a bushel, is equally impenetrable by the eye of man. If the lamps are to be carried and coddled at the same time let them be stowed in an inconspicuous locker constructed for the purpose, not paraded around in a manner suggestive of cocoanut shies and curling papers. But if bright lamps must be hid under a bushel, does it not suggest some other finish for the lamps? Something besides brass, such as oxidized iron, for instance.

NEW ENGLAND SHOPS ARE MORE THAN BUSY

By CHARLES B. HAYWARD.

IF those there be who are still skeptical regarding the present highly prosperous condition of the automobile industry, and the fact that the prospects for the coming year are far and away better than they have ever been at any time in its history, a visit to some of the New England factories would certainly do much to remove this impression. In some things New England is sectional, but as its automobile output finds its way to every part of the country, frequently being as well represented on the Pacific coast as it is in the East, there can be no doubt but that the prosperous conditions prevailing there are duplicated by other automobile manufacturing centers, and that the healthy activity to be found in every plant east of the Connecticut State line is reflected in the full-force working conditions of every automobile factory of note the country over.

Bridgeport Takes Pride in Locomobile Plant.

Bridgeport takes considerable pride in the presence of the Locomobile factory in that city, as was strikingly evidenced recently by its spontaneous outburst of enthusiasm on receiving the news of Robertson's victory in the Vanderbilt race, and its regard for the big plant as a home institution extends to its product as well, for to the Bridgeporter the Locomobile is the one real car, and he is willing to back his belief with his money, as is amply substantiated by the great number of locally owned machines. This pride is further quickened by the spick and span equipment of the fire department supplied by the home factory, and that the reputation of the Locomobile company in this field is not merely local is shown by the presence of several special jobs of this kind now under way at the factory for several other New England cities. Two of these are specially designed chemical auxiliaries and the other is a hose truck. All are being constructed on the regulation 40-horsepower, chain driven Locomobile chassis, a special feature being the use of pneumatic tires on all of them. The tire equipment is being supplied by the Fisk company, and consists of 40 by 6-inch rears, which indicates that New England municipalities are not averse to paying the price of speed when it is a question of getting there a little sooner.

These special jobs are naturally but a very small part of the activities of such a factory as the Locomobile plant, the bulk of the work now being carried on consisting of the first series of the new Model L shaft-driven "Thirty" Locomobile for 1909, which is already coming through in numbers. This is supplemented by the work on the 40-horsepower chain-driven car, which is being continued without any changes of importance for the coming season, and the calls for a car of this type show that it will be a long while before the chain-driven model disappears entirely, if such is ever the case, as for machines above a certain power it has many faithful advocates, who will probably always remain true to their convictions in this respect. This is shown by the remarks of former buyers of Locomobiles who have had an opportunity of viewing the new shaft-driven model. "It's a beauty, but a chain drive would make it perfect," sums up the opinions of many.

In the Making of Motors Particularly.

Although not exactly a New England shop, the Jencick Motor Company's location in Portchester, right on the State border, practically brings it within this category, as it is the first of a long line of plants extending along the shore that make a specialty of marine motors. In addition to its routine work of turning out both automobile and marine motors of smaller sizes after special designs, there is now nearing completion there an eight-cylinder, 200-horsepower motor the ultimate mission of which will be to "trim" the *Dixie II* at the motorboat carnival at Palm Beach next spring. It is intended to form the power plant of the *Richard Croker, Jr.*, the hull of which is now under construction at the Herreshoff works in Rhode Island.

Speaking of motors takes one back to Bridgeport, where the American & British Manufacturing Company has plans under way for a large output of automobile motors during the coming season. The products of this concern is already finding its way into the chassis of more than one assembled car in the East, and it will figure as the power plant of at least one car that will have America's automobile center—Detroit—as its home. Motors of about 25 and 40 horsepower will be specialized, and facilities of the company make it possible to turn these out in large numbers at figures which cannot be approached by smaller builders. The Bridgeport Vehicle Company and the Royal Equipment Company are two other members of Bridgeport's automobile population, and both are hard at work.

Automobile Interests in Every Town.

It is pretty hard to find a town in New England that does not contain at least one factory which contributes its quota to the sum total of automobile building in this country, and there are probably few whose product is more widely distributed than that of the Manufacturers' Foundry Company, located in Waterbury, just north of Bridgeport. Within a comparatively few years this concern has developed the art of automobile cylinder casting to a point where the foreign artisan can no longer compete with the American product. Just north of Waterbury, in the little town of Torrington, spark plugs and other small specialties are turned out by the Standard Company by the thousand.

A twenty-minute ride east from Bridgeport brings one to New Haven, which is the home of the Bowers carbureter, Mayo radiators, Gilbert fabric specialties, tire cases, and the like, and the Cowles and New Haven carriage mountings and trimmings, from which it will be evident that every place "Down East," whether large or small, has its representatives.

Half way between New Haven and Hartford is the town that is probably better known for its silver-plated ware than any other in the world, but in the past few years it has jumped into prominence as the home of the Connecticut coils and other ignition specialties made by the Connecticut Telephone & Electric Company, and the pressure under which this concern is at present running strikingly reflects the demand in general.

Corbins for 1909 Well Under Way.

Within less than half an hour's ride from Meriden is the plant of the Corbin Motor Vehicle Corporation at New Britain, where every effort is now being centered on the production of the new models for the coming season. The first series of the water-cooled Corbins is already well under way, and at this factory the testing cars are put to an even more strenuous test than that of the two or three hundred mile road run under the watchful eye of the factory expert that is ordinarily given them, as the makers of the Corbin utilize their testing cars to a large extent in doing freight duty between New Britain and Hartford, thus expediting the delivery of much needed materials, and at the same time giving them the preliminary running in and inspection that is an essential step in the history of the chassis as it progresses from the first stages to its final delivery to the purchaser. Naturally, the freighters form but a small part of the fleet of Corbin testers on the road, but this utilization of the cars is but one example of the little economies now being practiced by automobile manufacturers, such as the use of the current generated by motors on the testing stand. Formerly this energy was wasted by being dissipated through a resistance, and this is still a more or less general custom.

Since the introduction of the new type of ball bearing developed by Mr. Rockwell, of the New Departure Company, Bristol has come into prominence as an automobile town, and this is to be further accentuated in the near future by its posing as the sponsor of a fleet of taxicabs, which will be the product

of the Bristol Engineering Works, where their building is already well under way. It seems somewhat of a coincidence that Designer Moskovics should also be using his first cars as freighters, and the loads of parts and other materials that they are called upon to tote over short and comparatively long jaunts, such as to New Haven, give excellent promise of their durability in their ultimate field of usefulness.

Hartford Is An Auto Center.

With two large factories and a host of smaller interests, Connecticut's capital city can well lay claim to being a New England center of automobile activity. With the prospect of the plan of reorganization now afoot being speedily completed, the entire plant of the Pope Manufacturing Company has been rushed to more than its full capacity for some time, night work having been the rule for several weeks past. It is said to be the ambition of the Pope Company that every resident autoist should be the owner of a Pope-Hartford, and to judge from the number of cars of this make continually seen about the city, it would seem that this desire has been realized to a very great extent. What with the continual stream of testers issuing from the plant on Capital avenue and the preponderance of privately owned cars of this make that are to be seen on every hand, it strikes the casual observer as if there were nothing but Pope-Hartford cars permitted there.

At the other big Hartford factory present activity gives promise of a brighter future than appeared to be in store for it since the Packard negotiations fell through. It can justly lay claim to having been the first completely equipped automobile plant to be established in this country, and while some of its equipment may now be out of date, there are few factories on this side of the water that can surpass its facilities for turning out work, and by work in this connection is meant as much, if not more of the complete automobile than the average maker produces in his own shop. Some idea of what it is doing in a quiet way, and with far greater efficiency than was the case in its heyday, may be gained from the fact that between September 15 and the end of the year close to 200 of the 30-horsepower gasoline cars and 50 of the Victoria-phaeton type of electrics will not only have been manufactured, but actually sold.

Besides its two large factories, Hartford can boast of a multitude of interests devoted in greater or less measure to the automobile. It is the home of the Hartford and K-B universals, the Veeder tachometers, Richardson ignition specialties, and other parts makers, and is also the headquarters of one of the largest distributing houses, the Post & Lester Company.

Over the Commonwealth's Border.

Just above the Connecticut State line one strikes Springfield, which is congratulating itself on the excellent showing made by two Knox cars of stock pattern for 1909 against specially designed machines of far greater power in the Vanderbilt race two weeks ago, and when one comes to consider how very small these cars are compared with those built for nothing but racing, there is indeed good reason to marvel at their highly creditable and consistent performance, for, after all, what the buyer wishes most is endurance and reliability, and these were shown to a superlative degree. These two Knox cars of 38 and 45-50 horsepower respectively are the representatives of the Knox line for the coming season, on which the factory is now busy, and the prospects are that it will turn out more cars for 1909 selling than ever before in its history. Auto fire apparatus is also a Knox specialty to which considerable attention is being devoted, together with other commercial work.

Springfield is one of the few Eastern cities that can boast of being the home of a two-cycle car—the Atlas. One of the chief activities of this plant during the past year has been the manufacture of taxicabs, which are now to be seen in quite a number of the larger cities, and this will doubtless be the case to a far greater extent during the coming year, as with its extremely simple and reliable power plant the Atlas cab is one that can be entrusted in the hands of the unskilled driver with far greater safety than where there are a number of small parts to be monkeyed with. Although the success met with in this field has caused a large part of the company's time to be devoted to building cabs, the work of turning out the regular models for pleasure use has not been neglected.

In addition to turning out two and four-cycle cars, Springfield can probably lay claim to manufacturing more motorcycles and more metal bodies than any other American town, the works of the Hendee Manufacturing Company, makers of the Indian motorcycles, being close to the Knox plant, while the Springfield Metal Body Company holds forth in another part of town.

Chicopee Falls, while so close to Springfield as to be practically a suburb, is proud of its independence, and, population considered, there is probably no other town in the country that contains within its limited confines automobile interests of such importance, as it is the home of the Stevens-Duryea Company and the Fisk Rubber Company, the plants of both of which are running in full blast. To say that the town is "Stevens-Duryea" through and through is to put it mildly. Outside of automobile circles, it has a reputation as the home of the Stevens firearms, and it also contains other important factories, but in the past few years the big automobile plant, which is constantly enlarging, has overshadowed them all. At present it is running through two or three hundred of the new Model X, four-cylinder cars, the specifications of which were made public last Summer. And as things go quickly at the Stevens-Duryea plant, there are cars in swarms. Soon it will begin to turn out the first series of the "Big" and "Little Six" cars, which will come forth this year in a considerably altered guise.

As for the Fisk plant, the most that can be said of it is that it is turning out tires and then more tires, and as that is its business in life, what more is there to tell about it?

Activities Further Eastward.

Worcester has numerous auto interests in the shape of the Baldwin Chain & Manufacturing Company and the drop-forging plant of the Wyman & Gordon Company, that turns out crank-shafts and other forged parts in large quantities; the White & Bagley Company, oils; Coates Clipper Manufacturing Company, Graton & Knight, the Windsor Manufacturing Company, etc. Boston has a multitude of auto activities, particularly when its numerous outlying suburbs, such as Waltham, where the Orient is produced; Beverly, the home of the Cameron; Lynn, where the G. E. Co.'s auto shop is located; Amesbury, with the Gray & Davis lamp works; Jamaica Plain, with the Napier, and a host of others too numerous to mention, are considered. It is the headquarters of the National Brake & Clutch Company, of cork insert fame, beside a number of other accessory interests, and is considered the best auto selling center east of New York, besides being the sponsor of more freak designs than have ever come out of any one town. The E. T. Burrows Company is bending its efforts toward making Portland, Me., an automobile manufacturing town, and the result will probably be seen at the shows.

Turning southward on the circuit, one strikes Providence and Pawtucket, the former the home of the American Locomotive Company, which is at present very busily engaged on a number of things that it does not wish to say anything about, while its entire force is kept working at high pressure to turn out enough taxicabs to meet the demand, as this is a specially designed machine throughout, and is built independently of the line of four and six-cylinder pleasure cars, not to mention the attention that the company is devoting to commercial work.

The Brown & Sharpe Company, Providence Engineering Works, Standard Machine Company, and American Ball Company are some of the other concerns a large part of whose product goes to swell the city's automobile output. As the home of one of the Maxwell factories, Pawtucket is another Rhode Island city that can lay claim to automobile fame, and the activities of the Maxwell plant there bid fair to carry its name all over the country during the coming year, if not to more remote parts of the globe.

LETTERS INTERESTING AND INSTRUCTIVE

THE SPECIFIC GRAVITY OF GASOLINE.

Editor THE AUTOMOBILE:

[1,613.]—Tel me bow to read a Baumè hydrometer. The meter sank in tbe gasoline to 65 degrees. * * * * * *

Bastrop, La. A. G. KNOX.

The specific gravity, in degrees Baumè (equivalent) for liquids lighter than water, will be found (at a given temperature) by means of the Baumè hydrometer scale. If this hydrometer has also a thermometer, the utility of the same will be obvious, since the specific gravity and temperature may be noted simultaneously. A separate thermometer would answer the same purpose.

The specific gravity of the gasoline is not constant under conditions of varying temperature, and it is best to reduce the temperature (always) to the same point (say 60 degrees F.) before noting the specific gravity in degrees Baumè. The temperature can be regulated by merely submerging the test tube (holding the gasoline) in a bath of water and regulate the water temperature by means of ice or hot water.

In conclusion, however, it may not be out of place to state that gasoline is not graded by the refiners, on a basis of specific gravity, and it is probable that the specific gravity even when measured, will avail nothing at all.

The fractional distillates of the hydrocarbons are graded within limits of temperature, at or near the mean temperature of ebullition, of the components. It is the temperature of ebullition then (at the atmospheric measure) that is wanted; not the specific gravity (mean of the components). Since the value of fuel is dependent upon its adaptability and that, in turn, is governed by the temperature at which the gasoline vaporizes.

USE OF LIVE AXLE WITHOUT DIFFERENTIAL.

Editor THE AUTOMOBILE:

[1,614.]—Kindly advise me in your "Letters Interesting and Instructive" wbsther a 1,500-pound automobile, with 98 inches wheelbase, could be operatsd without a differential; by this I mean using a solid live axle. Or wouid the strains in rounding corners tend to break the axle and cause severe wear on the tires—these to be of solid rubber? Supposing considerable care was exercised in making the turns, could the automobile be handled successfully?

Staten Island, N. Y. HARRY LAWRENCE.

Unquestionably the automobile could be handled without the differential, but it would hardly be advisable to do so under ordinary circumstances, for every-day use. We believe that some machines of the high-wheel buggy type dispense with the differential, but these drive the rear wheels by ropes or wire cables, which allow a certain amount of slip. On the other hand, some high-powered racing cars have been built with solid live axles. If your machine is of the high-wheel type, and is not intended to make more than twenty miles an hour, you may do without the differential; but fitting one would be safer.

WHAT IS THE TERMINAL PRESSURE?

Editor THE AUTOMOBILE:

[1,615.]—I will appreciate an answer through "Letters Interesting and Instructive" to tbe following question: What is the pressure in the cylinder of a 4 by 4-inch motor just before the time of the opening of the exbaust valve, the motor, of the four-cylinder four-cycle type, running at 900 r. p. m. As the compression epace of the motor varies greatly, I will ask you to take any standard motor.

Nsw York City. C. N. H.

It might approximate thirty pounds per square inch. In a given motor this "terminal pressure" is a variable depending upon the conditions as follows: (*a*) the carbureter; (*b*) the areas of inlet valves in relation to the areas of pistons; (*c*) the shapes of cams; (*d*) the design of the intake; (*e*) the speed of the piston; (*f*) the leaks of compression will lower the pressure; (*g*) the efficiency of the spark; (*h*) the timing of the spark; and other minor details, as cooling, etc. A statement of pressure, then, is the merest approximation.

IS THE STROKE PRODUCTIVE OF POWER?

Editor THE AUTOMOBILE:

[1,616.]—Please state through your columns which of the following two engines will develop the most power going at the same speed. First one witb a bore and stroke of 4 1-2 by 4 1-2 incbes, and one with a bore of 4 inches and a stroke of 4 1-2 inches.

East Orange, N. J. SUBSCRIBER.

$$H\ P\left(\frac{d^2\ l\ n\ s}{10^9}\right)4$$

When d^2 = square of bore of cylinders in millimeters;

l = stroke in millimeters;

n = number of cylinders;

s = speed of crankshaft r. p. m.:

For the $4\frac{1}{2} \times 4\frac{1}{2} = 108 \times 108$ m/m, approx.

$$H.\ P. = \left(\frac{108^2 \times 108 \times 4 \times 1000}{10^9}\right) 4 = 20, \text{ approximately.}$$

For the $4 \times 4\frac{1}{2} = 101 \times 108$ n/m approx.

$$H.\ P. = \left(\frac{101^2 \times 108 \times 4 \times 1000}{10^9}\right) = 17.6, \text{ approximately.}$$

This is on a basis of 1000 revolutions per minute, which is not the maximum power speed. The probable maximum (conservative) speed would be about 1300 r. p. m. You ask for the relative ratings however; hence, the maximum power speed may be disregarded.

KEROSENE IS BETTER THAN NOTHING.

Editor THE AUTOMOBILE:

[1,617.]—I am very much interested in "The Automobile," and look forward eagerly to each new issue. "Letters Interesting and Instructive" are of much value and may be made more so if careful observers will report their experiencee. Automobile "doctors" certainly disagree widely and a driver of small experience is at his wits' end to know wberein the truth lies.

Your answer to "A. G. D." about the kerosene treatment for carbon deposits in cylinders would indicate a very limited experience for the writsr when be says: "We have never heard any objections to this practice and do not see any cause for them except laziness." I have found it a frequent topic of inquiry and argument when two or three of the elect are gathered. The makers of my car, a four-cylinder, 35-horsepower, advise its use, but their New England road expert (endurance driver and Glidden "godder") says no, and I have followed his advice the last 1,200 miles witb good results. Why does a certain decarbonizer advertieement say, "No kerossne"? To me that suggests the existence of an adverse opinion.

As regards decarbonizers, it ought to be known by this time whether they will do the work without injury to the engine. If they have not got it right yet, they will soon have it. One of tbe oldest and greatest scientific authorities writes me: "We have independent information of tbe successful use of a chemical compound for the removal of the eolid products of combustion deposited upon cylinders and valves of automobiles and similar engines. It is guaranteed not to damage the metal in any way, simply volatilizing the carbon which passes out of the exhaust with the gases of combustion."

Descending hills I cut out the spark and give the engine about all the gas it will take, and have an idea it serves to clean out the cylinders, etc. Is there any efficiency in that? Does it serve any good purpoee to apply kerosene along the eides of the springs?

Have tests ever been made to determine how far a given amount of gasoline will drive a car at different speeds; in other words, what is tbe ratio of increased fuel consumption to increase of speed? J. H. NETTLETON.

New Milford, Conn.

Irrespective of the incidents in the history of this subject, it is a fact that kerosene oil has been much used in cylinders to avoid evil influences of carbon deposits. One of the companies at one time provided facilities, by way of a tank of kerosene and suitable means, by which the operator of the car could inject kerosene oil into the cylinders at frequent intervals.

Motors so treated seem to thrive and the carbon deposits do not seem to grow in the cylinders. A great many people have used kerosene oil in the cylinders for the same purpose, and the kerosene undoubtedly will creep in behind the crust and loosen

the same from contact with the metal; once loosened, it will, of course, blow out as soon as the motor is started.

If you used a decarbonizer (and the same is efficient for the purpose) it would seem superfluous to employ kerosene oil as well. As to the efficiency of decarbonizers, there seems to be no question at all, and they differ from kerosene oil in that they prevent the forming of any considerable crust, whereas kerosene oil will loosen the crust after it is formed. One is a preventive; the other a cure. Wisdom dictates the use of the preventive, and if the makers of the decarbonizers guarantee that they will not etch the polished surfaces of the cylinders, the guarantee may he taken no douht, since they are the best judges of what they use and its action on metals.

You can best scavenge your motor on a descent by cutting off the gasoline and allowing a free circulation of air; if you are not equipped to separate the gasoline from the air, the presence of the same will do no damage unless by a "muffler shot" when you switch in the spark. Springs should not have an application of kerosene oil; it is better to jack the body upwards to relieve the springs of their weight, pry the leaves apart, and, with a squirt can, apply oil to the bearing surfaces of them. The leaves are concave, thus affording a space for this oil, and the slippery surface resulting will prevent squeaking, on the one hand, and the unequal distribution of strains on the other; while it is true as well that rust formations will be absorbed.

The fuel consumption will depend upon the wind resistance above 20 miles an hour, and the wind resistance in turn depends upon the front area of the car. Simultaneously with these considerations will be the question of the road condition, as it will affect the mechanism of the car, etc. Below the point at which you have to take into account wind resistance, the fuel consumption will be proportional to the power required to drive the car, if the carbureter is exactly suited to the purpose and if the motor is driven at its most efficient speed, which demands that all speed changes be made through the good office of the gear set.

Having fixed all of these conditions, if you then determine the draw-bar pull of the car (which is not the same for all cars) and the gasoline required per ton mile at that draw-bar pull, the consumption within the limit stated may then be approximated. We have records of tests of this character under conditions of actual practice, but they are of no value whatever excepting in connection with the very car involved.

SOME FINE CARS HAVE WOOD FRAMES.

Editor THE AUTOMOBILE:

[1,618.]—I am planning a light runabout and would like to know if you think a frame built of hickory or white oak would be efficiently etrong to eupport about 750 pounds and etand the usual road straine and ehocke. The car ie to have a wheelbase of about 90 inchee. Of hickory or white oak, which is the best suited for the purpoee? What would be the proper dimensions of the wood for a frame of thie kind? AN INTERESTED READER.

New York.

Either hickory or white oak, if well seasoned and second growth, would suit your case admirably. It is not so easy to fit the dimensions without knowing as to the locations of the laterals. If laterals come well spaced the thickness of the side member can be reduced, and vice versa. As a general statement, we would think the section might be one and one-half inches thick by four and one-half inches deep, and that the side members could he tapered off to three inches at the ends. The iron work will have some to do with the ability of tlie finished frame, but these are all matters in relation to which you are no doubt already well informed. Ash, rather than the woods you mention, is employed altogetber by the makers of the Franklin cars, owing to its great resiliency. It is made in laminated form.

MR. SOREHEAD ON THE CHAUFFEUR.

Editor THE AUTOMOBILE:

[1,619.]—The word chauffeur is a name applied to that species of genue homo which causes the benzine-propelled phaetone to climb walls and frighten street cars. This name hails from France, the cradle of the motor car, and hae the literal meaning of "firsman"; many persons agree that this appiles to their post-mortem vocation. To be a chauffeur is to rank among "the chosen," as the more earthiy of the ewarm will deign to inform you; wbo does the choosing may be readily imagined from the reverent expietives in common use among the ieather-clad brethren.

Some few of theee reckless road-kings can lay claim to an efficient training in cushion-greasing and lamp-breaking, but the majority wear a tin breastplate labelled "License" only for the reason that Fortune turned over the required fee as the result of a good poker hand. To the uninitiated it would appear that the duties of a chauffeur would be the care and operation of the vehicle in hie charge, but in reality hie sole obligation is to accept his "salary" from that favored mortal, hie employer. When you ask what the owner has to cash up for the privilege of occupying ths left front seat, the chauffeur will haughtily aesert, ae he tucks in his paper collar, "Forty per." But to see him in his glory you must invade the evil-smelling interior of a garage, where in a far corner you may observe one of "the boye" produce an inner tube from his chariot and hand it quickly to a novice owner, receiving in exchange a substantial roll of the pea-green scrip. You may wonder if this is a practical demonstration of graft, but be wise and refrain from inquiry.

In another corner of the shop, a pair of French heels loom up under a front axle, and there is a buey "tap, tap" of a hammer and chieel upon eome bolt-head whose spanner had been sold for the price of a hop-soda. Suddenly there is a dull thud and "'mid eounde unholy" the hammer goee skimming across the concrete floor, finally taking paint from a wheel freshly painted. The eulphuroue vapor ie even woree than the richest mixture his ignorance can produce. Compared to this lurid blasphemy the vocabulary of the ecafaring tar ie but infant'e prattle. Pulling your fingers from your ears on a quiet eide etreet, you recall seeing the advertisements giving among the attainments, "three languages spoken." It is easy to realize the advantagee enjoyed by an accompliehed linguist both in the matter of alleviating pain and in frightening the refractory machine into docility.

While you ruminate upon the peculiar features of this estimable profeeeion, a big car comee up the pike with the lateet automobile raiment behind the wheel. Ae you ehrink back against a building, the flying juggernaut dashee for the curb and stops with a heaven-reaching screech one-quarter inch from the back end of a big dray. Your heart stande etill as the thing at the wheel riees and stalke toward you. His floating robes seem about to enguif you and hie goggle-eyee burn from the deviliah racing hood. It speaks: "Say, feliah, yuh ain't got a hell-stick, hev yuh?" Recovering your breath, you hand over your "iast" and watch "It" speed away—on the high gear from the etart. What a creation! Small wonder equinee refuee to ehare the road with euch evil-looking goblins. But many of the so-called "mecaniciene" require a rather extensive wardrobe to cover their ignorance of things automobile. Would that their gallantry and courtesy aleo rivalled the ancient knight.

One deiightful pastime indulged in by the gasolins fraternity causes more nervous wrecks and loss of weight than sanatariume and weighing machines can take care of. To get experience in person—or rather body—seek the busiest corner of your city, and when the traffic becomes hopelessly congested, etart for the opposite sidewalk. Invariably a big dray will oppose your progress, and you turn back, but—"Honk!"—a steaming foreign radietor punchee you smartly in the ribs. Amid the picturesque reprimande of the chauffeur, you weakly drag your trembling limbs to the sidewalk. It avails naught to glare and curse at the receding auto. Be satisfied you are not "pinched" for marring that expensive cooler—the car wae only going "twenty" anyway.

The curse of the American highway! Prison stripes for 'em all! Sour grapee? Rot! Why, you wouldn't be claseed in that "Auto School" your eye hae caught an "ad." of in the paper you're waving about. "$300 a month guaranteed. Latest French models." Oh, possibly there are a few decent men at the business, and even if there are none, you carefully cut out the advertisement as a means to uplifting the profeeeion. L. D. F.

Auburn, N. Y.

KENTUCKY WANTS TO SEE THE GLIDDEN TOUR.

Editor THE AUTOMOBILE:

[1,620.]—I am making an effort to have the next A. A. A. tour for the Glidden trophy come down into Kentucky, and it is my suggestion that the tour start from Chicago and the route include South Bend, Kokomo, Ind., Louieville, and Bardstown, visit the Abbey of Getheemani, Lincoln Memorial Farm, and Mammoth Cave, then by way of Evansville to St. Louie and to Denver. The Lincoln Memorial Farm at Hodgeville will be dedicated as a national park before the 1909 tour. Mr. Glidden writes me that it would afford him a great deal of pleasure personally to have the tour come to Kentucky. "Collier's Weekly," because of its interest in Lincoln Farm, ie also intereeting iteelf in having Kentucky included in the route. CLAUDE W. WILSON.

Bardstown, Ky.

THE Autocar Company of Ardmore, Pa., has entered the field of the commercial vehicle, and has put on the market an entirely new line of cars. Fads and sensations, by the way of new models each year, have been dispensed with, and these new cars, instead of being called 1901 Autocars, will be "Type XVIII" cars, following the policy of bringing the construction to a standard manufacturing basis.

Two styles of chassis have been designed: first, with a long chassis and solid rubber tires; and, second, a shorter chassis, using pneumatic tires. The long chassis is intended for light delivery work with 2,000 pounds load capacity. This chassis can be fitted with open or closed delivery bodies or with a twelve-passenger bus body. The short chassis is intended for passenger work, and can be fitted as a town car, victoria, or station wagon body. For certain chassis of light, quick delivery work it can be fitted with a small box body.

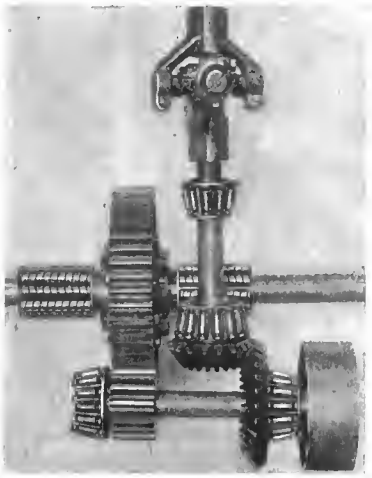
Most Commodious Bodies.—In order to get a maximum size of body on the shortest possible wheelbase, the motor is located under the driver's seat. This seat structure is separate from the body proper, and either can be removed without the other. Accessibility to the motor has not been compromised by this location. Small doors at the side of the seat provide easy access to the spark plugs and valves. The seat itself is hinged, and the whole structure may be thrown back, as shown in one of the illustrations. The motor and transmission case are mounted upon a pressed steel frame, the motor is secured by four bolts, through feet on the sides of the cylinders, and the transmission case by four bolts, through its legs. The removable power plant eliminates the necessity of spare cars in any delivery service, as an extra power plant only need be substituted while repairs are being made on the original one.

Some Power Plant Features.—The motor is of the two-cylinder opposed type, 4¼-inch bore by 4½-inch stroke, and is rated at 18-horsepower (A. L. A. M.). The cylinders are of a fine grade of grey iron, rough bored, annealed, finish bored, ground to size, and finally lapped in with pistons and rings. By means of this method of manufacture a perfect fit is assured. The valves are both on the upper side of the cylinder, and can be readily removed. They are both mechanically operated from the same camshaft and are interchangeable. The valve heads are of such shape that warping is reduced to practically zero, and that in case of a valve head cracking it cannot enter the space traversed by the piston. The pistons are of the same grade of grey iron as the cylinders, and are accurately ground to size before the lapping operation. They are fitted with three 5-16-inch piston rings, all located above the piston pin. The piston pin is hardened and ground to size, and is held in place by means of a "snub" and spring. The connecting rods are of high carbon steel, drop forged and heat treated. The piston pin and crank pin bearings are of bronze. The crank pin bearing is adjustable, the cap being held in place by means of two 9-16-inch bolts. The crankshaft is also of high carbon steel, drop forged and heat treated. All journals are accurately ground to size. The crankshaft is mounted on extra large Hess-Bright ball bearings of the silent type, and carries two flywheels, one on each end. The front flywheel has fan blades cast in it. In the long chassis this flywheel carries a throttle governor which limits the speed of the motor to 1,300 R. P. M. The rear flywheel carries the clutch.

Showing the Accessibility of the Autocar Power Plant.

The crankcase is split horizontally into two parts. The lower part carries the cylinders, crankshaft, water pump, and camshaft, while the upper part carries the push rods and guides, the magneto, the oiler, and a gear for driving the water pump. This part of the case is easily removable, carrying its parts with it, and giving access to the crank pin bearing, without dismantling the motor. The magneto is standard equipment, and is attached to the top of the crankcase by

means of two winged holts. It can he removed and replaced without altering the timing. This magneto is of the low tension type, delivering its current to an induction coil, mounted on the side of the seat structure. Thus, a dual system of ignition is provided. The oiler is of the force feed type, and delivers the oil, through a sight feed, to the crankcase, whence the cylinders, camshaft, crank pins, etc., are lubricated hy splash. The oiler is hcld in place hy a single winged holt and dowel pins, secure, and at the same time easily removable.



Rear Axle Double Gear Reduction, and Roller Bearings.

A Very Satisfactory Transmission.—The clutch is of hronze, floating ring provided with cork inserts. The forward end of the clutch shaft is centered in a bearing in the rear end of the crankshaft. The transmission is of the progressive sliding gear type. The countershaft is located below the main shaft; all shafts rotating on Timken roller bearings. The case itself is cast in one piece, with two hand-hole openings. The hand-hole opening permits the adjustment of the gear shift fork. The sliding train operates on the squared main shaft, and provides three forward speeds and one reverse, high speed, direct drive, through the transmission.

The power is transmitted from the gear case to the rear axle through two universal joints and a drive shaft. The rear axle contains a douhle gear reduction. The bevel pinion, connected at the end of the drive shaft, drives a large bevel gear on a short transverse jackshaft. From this shaft the drive is transmitted to the differential housing by means of a pair of large spur gears. The bevel pinion shaft and jackshaft run on Timken roller bearings, which are mounted in caps, screwed into the axle housing. One of the jackshafts extends through this housing and has the emergency brake drum mounted on it.

Axles, Wheels and Control.—The live axles are heavy, and are provided with squared ends. The square on the inner end slips into the differential gear, and it, on the other end, drives the wheel which is secured to it. These axles are mounted on Hyatt roller bearings, at their inner ends, and on Timken roller hearings, at their outer ends. The thrust of the wheels on a curve is taken through the two axles to the Timken hearing on the inner side of the curve. The axle housing is of malleable steel throughout, and is in five pieces. The spring seats and brake supports are integral with the tubes, and no parts are riveted.

The front axle is tuhular with the Elliott type of steering knuckles. The spindles carry Timken roller hearings, on which the wheel huhs are mounted. The cross-link, connecting the two knuckles, is in front of the axle, and the steering link lies transversely across the car, connecting the steering gear arm to the knuckle arm on the opposite side. One foot pedal controls the clutch and the other the service hrakes on the hubs of the rear wheels, while the side hand levers control the gear shift and emergency brake. When the brake lever is applied the clutch is automatically released before the hrake tension is noticeable. The steering gear is of the hevel and sector type. Two short levers above the wheel control spark and throttle.

The Armored Wood Frame.—The frame is of armored wood, constructed of pressed steel channels, reinforced with wood members. The front springs are semi-elliptic, and the rear springs are full elliptic.

The wheels are of the artillery type and constructed from selected hickory. On the short chassis they are equipped with Goodyear detachable rims and 32x4 pneumatic tires, and on the long chassis with 32x3½ solid tires. The short chassis has a wheelbase of 85 inches, accommodating a hody platform 48 inches wide and 68 inches to 90 inches long if so desired. The long chassis has a wheelbase of 97 inches, accommodating a body platform of 48 inches wide and 80 inches to 100 inches long.

WINTON SECOND "UPKEEP" CONTEST BEGINS.

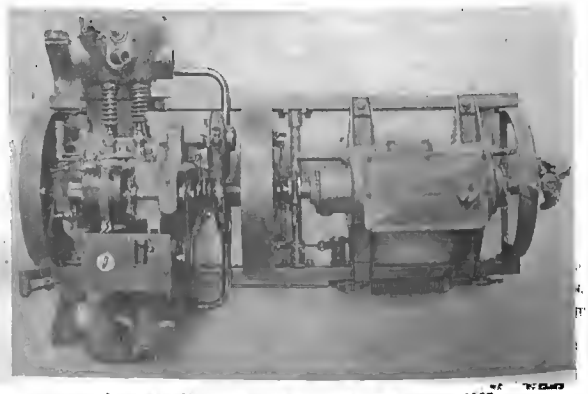
The second annual $2,500 upkeep contest for Winton "Six" chauffeurs opened November 1 and will continue to June 30, 1909. Contestants must he employed drivers of Winton Sixes, any model, and will he required to file monthly reports of mileage and expenses. At the end of the contest these reports will be passed upon by a committee of disinterested judges, who will award the cash prizes. The chauffeur making the best service record will receive $1,000. Second prize is $500, third $250, fourth $150, fifth to tenth $100 each. There is no entrance fee.

It will be recalled that the ten winners in the first annual contest drove their cars 65,687.4 miles on an upkeep expense of $15.12, an average of $1 for each 4,343 miles, or less than 25 cents for each 1,000 miles—unquestionahly a world's record.

"We are reaching the point in the automobile industry," says Mr. Winton, "where upkeep expense is of cardinal importance to buyers, and we propose to prove hy these public tests—all records open to every interested person—that Winton Sixes are the best investment the market affords. Low upkeep expense signifies more than ahsence of repair bills—it means continuous, satisfactory service, hecause the car that encounters repair bills is also a car that disappoints its owner in the character of its performances."

FAVORABLE CUSTOMS RULING ON FORGINGS.

It has taken the Board of United States General Appraisers just two years to decide that drop forgings are forgings and should be admitted as such when imported from abroad. Thomas Prosser & Son, New York agents for the Krupp firm, have been importing connecting rods, crankshafts and similar parts made hy the drop-forging process, and the government decided they were "manufactures of metal," accordingly assessing them 45 per cent., instead of 35 per cent., which is the duty on "forgings." Two years ago, a suh-hoard of appraisers reached the same decision, hut the question was then taken out of its jurisdiction and litigation extending over the interim has been necessary for the general board to determine the merits of the question of whether a piece of metal that has been die-forged is really a forging.



Autocar 18-horsepower Power Plant for 1909.

Rapid 5-Ton Truck for 1909

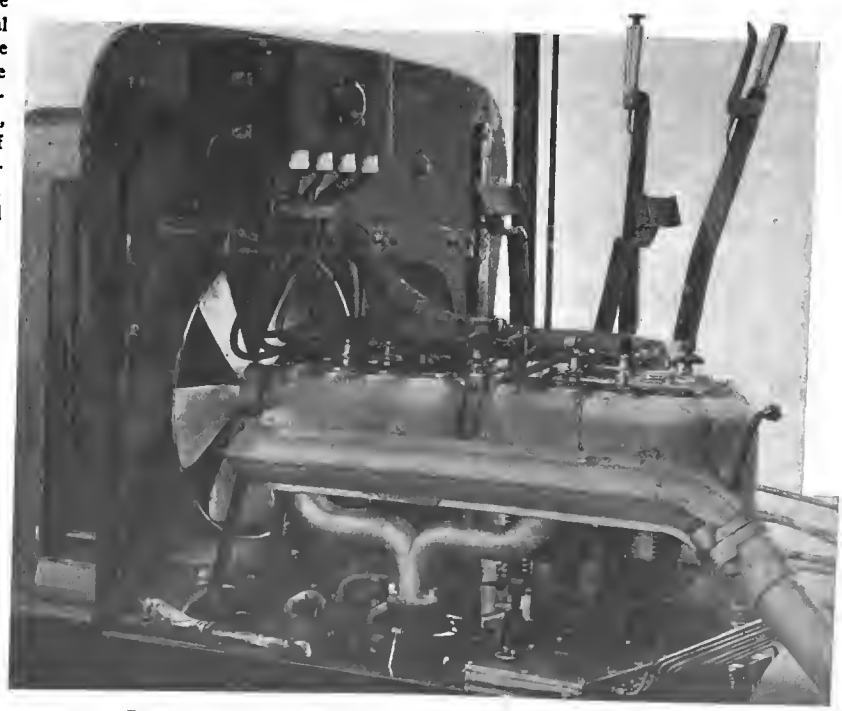
THE illustrations will show better than a word picture, the symmetry and strength present in the design of this bidder for utility favors. In commercial work, involving unskilled labor more often than not, the power plant is of the utmost importance, and in connection with this truck, an effort has been made to so perfect the several features, as to eliminate the squirt can, the screw driver and the monkey wrench.

Motor Characteristics.—The motor is of the four cylinder type, conventional four cycle, 5 1-2 x 6 1-2, bore and stroke respectively and is rated by the makers at 60 horsepower. The cylinders are cast in pairs, water cooled, with integral head and this difference, *i. e.*, the heads of the water jackets are separable. This construction permits cores to be properly centered; the complete removal of core sand, and, after cleaning, if the occasion in service should require. The pistons are long, packed with four concentric rings, with intervening oil grooves, while the cylinders and the pistons are of a special close grain iron. The crankshaft is of nickel steel, forged and "slabbed" and after profiling is machined with an allowance for grinding. For the connecting rods drop forgings are used, the same of a special grade of toughened steel, while the wrist pins are hollow, hardened and ground.

Realizing the arduousness of the service and the lack of attention the plant will be given in the ordinary run, the projected area of the respective bearings is greater than that likely to be found in other branches of service and sufficient to assure long life and the absence of annoying, if not costly, interruptions. The valves are large with special nickel steel heads and carbon steel stems in long guides. The cams are separable on a special steel camshaft and impart a silent, uniform motion. The half-time gears are separately housed, which housing in turn is packed with grease. The water circulation is by means of a gear-driven centrifugal pump, while the cooler is adequate in point of capacity to abort steaming. Lubrication is by splash with suitably devised oil ducts and troughs, assuring a slippery surface and a profusion of the oil supply at every zone of pressure. The ignition system consists of a magneto on the valve side of the motor, with an auxiliary battery and spark coil system for cranking, and if the magneto fails, which, however, is a remote contingency, there are other nice features in connection with this power plant, as for illustration, the exhaust manifold is of large diameter and separably flanged, moreover, the intake is designed with a view to a continuity of the flow of gas and is separably flanged, and we might say, before departing from the subject, that there is a certain nice symmetry about these features that extends beyond utility and pleases the eye.

Transmission System.—Beginning with the clutch, it is to note a multiple disc type, housed in the flywheel, the numerous discs submerged in oil, backed by ample surface, assures a continuity of the clutching functions. From the clutch, the propeller shaft is short, and is terminated in a universal joint at both ends. But there is no perceptible angularity of the transmission, hence the joints are required to do no more than to transmit the power and take care of mere deflections. The transmission set is of the selective type with chrome nickel steel gears, from materials by "Krupp," and an assurance of life, aside from nice material, come by way of a coarse pitch of the teeth and a wide face of the gears. Flanging is resorted to wherever possible, as for illustration, the flywheel to the crankshaft and the bevel gear to its shaft.

The truck is the product of the Rapid Motor Vehicle Compan, of Pontiac, Mich.



Power Plant of the Rapid 5-Ton Truck as Seen from the Left Side.

THE AUTOMOBILE FOR JUVENILES COMES AT LAST

A NEW company has been started at Newark, N. Y., styled the Omar Motor Company, to build the "Browniekar," a car suitable to place in the hands of youthful autoists. An inspection of the illustration showing the car, will indicate that it is a very graceful little automobile most comfortably arranged, and sufficiently racy in appearance to send a thrill of pleasure through the hearts of juvenile auto aspirants.

Motor of the Browniekar.

Besides affording a real car, with an actual power plant, and all the facilities of an automobile, the designer very cleverly kept uppermost in mind the need for simplicity, on the one hand, and safety on the other. The car is very light, hence the impact, should it collide with an obstruction, will scarcely be felt at all. The mechanism is accessibly situated, and a good deal of thought has been given the details thereof, rather with the hope that repairs will be a minimum, yet easily effected, should the occasion require.

The Power Plant Complete.—The motor, it will be noted, is of the single cylinder, vertical type. As will be noted it is of the water-cooled genera, with integral jackets, mechanically operated exhaust valves, while the inlet is automatic. Care has been exercised not to overpower the car, but rather to provide a harmonious relation of the power of the motor to the weight of the car, in view of a safe speed. The control of the speed is through spark and throttle, with a speed range from a maximum of ten miles per hour down to a minimum, dictated by necessity. The clutch is nested in the flywheel, as the illustration plainly shows, which clutch, in turn, is actuated in the usual way, through the good offices of suitably disposed foot pedals.

The Transmission and Other Features.—The speed control is by a clutch pedal, operated by the left foot. When this pedal is pushed forward it tightens a belt and drives the car in a forward direction, while, if the pressure is relieved, the belt slacks. A second pedal, operated by the right foot applies the brake during the interim of slack belt and stops the car. With the idea of illustrating something of the efficiency of the transmission, the designer of the car states: "The car will make from thirty to fifty miles on a gallon of gasoline, while a gallon of cylinder oil will serve during a period represented by from five to six hundred miles of travel."

The Body Work and Finish.—The body is of metal, roadster type, with metal mudguards, and a bonnet of the same material. The finish is what the designers style "medium red, with a black stripe." Oil, sidelights and a tail-lamp are shown, the steering wheel tilts at a rakish angle, and the general appearance is brought up to a high standard. The approximate weight of this car is some three hundred pounds, which is brought about by divers economies of design, taking advantage of the thermo-syphon system of water cooling, and such other modes of procedure as are well known to designers of skill. The builders of this car lay stress upon the particular features, viz.:

The Browniekar—An Auto for the Younger Generation.

(*a*) The "Browniekar" is an automobile possessing all the usual functions as respects power and control.

(*b*) Its perfect simplicity and harmonious relation of parts indicates economy of maintenance.

(*c*) An eye to safety in the hands of juveniles was considered *first, last, and all the time.*

NORTHWEST WANTS AND IS BUYING AUTOS FOR CASH

MINNEAPOLIS, MINN., Nov. 2.—The most noticeable thing to be heard among the dealers in this territory, is prosperity. The reason is the abundance of money in the vicinity, and the readiness of people not heretofore in the market for cars to listen to the arguments of the dealers. Judging from the recent activities of Eastern factory representatives, the Northwest will at last be accorded that recognition for which it has been fighting for several years past. The recent panic and the subsequent showing made by Minneapolis and surrounding towns seems to have caused an awakening among the Eastern manufacturers, who now seem to realize that territory with acres and acres of good wheat land working to bring in the money, with wheat a dollar a bushel, is worth of the closest attention.

Vic Syromquist, for years identified with the Packard interests in this city, has closed with the Corbin people and for the present is located on South Sixth street until his new garage building on "Motor Row" is completed. The Corbin car is fairly well known in Minneapolis, although it had not had active representation for some time. Stromquist has a roadster demonstrator and expects to be able to make early deliveries.

Kemp Brothers have closed with the Brush runabout and have begun receiving them in carload lots. This firm is also carrying on negotiations for a line of higher priced cars.

Harvey E. Haynes, brother of Mayor Haynes, besides the Welch car, has closed with the Pennsylvania people and is looking for quarters in the neighborhood of "Motor Row."

The Fawkes Auto Company, handling the Rambler and Overland, have added the American to their list and have commenced taking orders right from the start.

An evidence of the general Northwestern prosperity is the fact that the Pence Auto Company, selling the Stevens and Buick lines, have placed an order for 1,800 (eighteen hundred) cars for the coming season. This includes the runabout and buggy types of Buicks and the Stevens touring car.

USEFUL THINGS FOR THE AUTOIST TO KNOW

THE proper lubricant for the bearings of the water circulating pump is a stiff mineral grease similar to vaseline. Grease containing animal fats softens considerably under heat, and is melted by the water and carried through the circulating system. Mineral grease, on the other hand, retains its consistency up to fairly high temperatures and is also very much better adapted for this use than other grades. A good grease will frequently serve to keep the pump from leaking where the packing is no longer what it should be and tightening the gland nut is of no further avail.

Feeding Mineral Grease to Bearings.
